# LATENT-SPACE-REASONING: THE COMPLETE RECORD (December 2025 - September 2026)

*The sole surviving artifact. 1,540 git commits across ten months, ~1,085 ledger rows in the modern era, 50+ adversarial audits in the classical era plus 14 in the modern. Every campaign, theorem, number, failure, and lesson - written for a reader with no repository access.*

# PART 0 - THE TRUE ORIGIN: THE EVOLUTION ENGINE ERA (December 2025 - May 2026)

## 0.1 The founding idea

The project began (December 8, 2025, initial release) as a Latent Space Reasoning Engine: treat a frozen model's latent generation path as an editable, inspectable search space. Target loop: sample -> inspect -> repair -> aggregate -> verify -> realize. The first era (~200 commits through May 2026) built an evolutionary search over latent perturbations:

- Evolutionary latent search with survivor decay, score caching, diversity features to prevent collapse (V2-V10 verifiable evolution iterations with review-driven redesigns).
- Hyperbolic latent geometry: GeometryConfig, HyperbolicMutation on the Poincare ball, HyperbolicCrossover via Karcher-mean barycenter, MixtureCurvatureMutation with per-individual curvature co-evolution, Poincare CMA-ES (low-rank covariance adaptation on the Poincare ball).
- Information-geometry steering: dual steering module with Newton logit steering.
- Soft-prompt experiments with attention-masking interventions for the attention-sink hypothesis test.

## 0.2 The perturbation paper (the era's flagship)

Prepending random embedding-scale tokens to a 4-bit quantized Qwen3-4B produces a sharp, non-monotonic improvement in chain-of-thought arithmetic: two random tokens raise mean accuracy from 32% to 51.6% (+19.6 pp) across ten independent directions; one token 42.7%; three or eight revert to ~44%. A first-token logit probe confirms perturbation does NOT activate reasoning mode (already saturated >99.99% under thinking-enabled decoding) - it modulates the downstream trajectory. Different directions solve different task subsets: ten two-token directions collectively cover 100% of tasks vs 80% (three-token) and 92% (eight-token); the three-token oracle is a strict subset of the two-token oracle (over-perturbation contracts the reachable task space). Cross-model: Qwen3-8B 8-bit +12.8pp (oracle 80%, McNemar 16/0), DeepSeek-R1-Distill-1.5B (oracle 100%, McNemar 6/0), phi-2 +6.7pp out-of-family. A paper draft carried the result with oracle coverage-vs-budget as the main figure.

## 0.3 The era's hard lessons

- STRONGLY EXPLOITABLE finding logged honestly during soft-prompt work: 32% accuracy range across random latents (p=0.006) - the latent scorer itself was gameable, seeding the later rule that automated scorer numbers are evolutionary guidance only, never quality evidence.
- Verbosity-inflation artifact caught and fixed (response/response_raw bias) - the template for later artifact discipline.
- The era closed when the nested-arithmetic capability claims were WITHDRAWN (Part 0.5).

# PART 0.5 - THE DIFFUSION REASONING PROGRAM (May - August 2026, ~330 commits)

Between the engine era and the native-math pivot sat a substantial diffusion-language-model program:

 DIFFUSION LATENT REPAIR (the promoted public result): fixed denoise 0.412 -> latent repair 0.531 at 2.6x GPU cost (lower-cost point 0.509 at 2.4x) on the lean mixed benchmark.

 MULTI-LATENT AGGREGATION v10/v11: v10 (48 fresh tasks) 40/48 coverage, 40/8/0 W/T/L, lift +0.077, zero contradictions; v11 (96 tasks, LLaDA-only) 87/96, lift +0.100, Wilson lower 0.831 - all 13 frozen gates passed with 2x replication. But the rubric was gameable (keyword audit RED).

 BLINDED PAIRWISE (N=50): task-specific clauses preferred 33/50 (66%, p=0.016) - confirmatory GO.

 V12 FILTERED REPLICATION (116 fresh tasks): NO-GO on the Gemini judge family - generic clauses BEAT task-specific (63 vs 53); same-vendor confound (generator and judge both Gemini).

 SEPARATRIX PROBE: interior correctness islands in 26/35 tasks along wrong-to-correct interpolation paths; bifurcation analysis found only ODD transition counts (a geometric constraint: wrong-to-correct requires odd crossings), mean 3.0 transitions/task; exploratory only (determinism, endpoint-selection, and norm-preserving controls lacking).

 The diffusion theory effort (30K chars of half-formal theory; claim ledger; ~23 numbered value-model/probe versions including span probes, retention gates, KV tomography, counterfactual probes, phase measurements) - archived when the program pivoted; retained as historical evidence.

 HARDWARE-DEPENDENT DECODING DETERMINISM (surviving finding): GH200/CUDA-13 runs differ on 2/5 sequential repeats; 8 byte-identical batch rows give 13/40 distinct completions; RTX 5090/CUDA-12.8 bit-identical across three processes. Embedding perturbation is a causal diversity source ONLY on deterministic stacks - any diversity claim must report the stack's noise floor.

 THE NESTED-ARITHMETIC WITHDRAWAL (August 2026, the era's terminal correction): the "perturbation unlocks capabilities that scaling cannot" claims were withdrawn after independent reanalysis showed 76-100% of every published rung was THINKING-MODE TRUNCATION, not arithmetic. --no-think at the same cap takes Qwen3-32B from 0% to 100% and every rung 1.7B-32B to 96-100%. What survived: under a binding cap, perturbation shifts trajectories toward completion (100/100 completed-correct; termination 24%->38%) - irrelevant on arithmetic where no-think is cheaper and better. The correction record became the template for every later correction: full public record, claim map, ground-truth index.

## PART 0.7 - THE NLM ROUNDS: THE FIRST NATIVE-MATH ATTEMPT (August 27-29, 2026, 37 rounds, 22 audits)

After the native-mathematics direction was set, the first measurement program ran as numbered rounds with formal audits, on DINOv2/Qwen3 chart worlds:

 NLM-001 (lexical next-token-KL instrument): BOUNDED NEGATIVE FALSIFIER - native calibration KL did not beat a learned diagonal metric on contextual hidden states for held-out closeness orderings (Qwen3-0.6B Delta = -0.058 [-0.22, +0.03]); a taxonomy leak in the authored probe set was caught and removed.

 NLM-003 (R-metric vs F-Fisher): the apparent R win (0.734 vs 0.630) was a TAXONOMY LEAK - the required sensitivity rerun removed PB_coarse and reversed the result (R 0.586 vs F 0.667). Claim withdrawn. Cosine and Euclidean still dominate both leak-free native candidates - the first clear statement that imported metrics were beating the native attempts.

 NLM-004 (random-init null): trained chart structure is real (cosine fine-label 0.946 trained vs 0.575 random-init; kNN 0.761 vs 0.069) and separate from cheap image statistics; but affine interpolation smoothness is an imported chart path, not native evidence.

 NLM-005/006b (transport/substitution in DINOv2): the label-preservation rule failed (crop50 0.458, invert 0.317, mix50 0.185, occlude50 0.416 - all OOD); non-diagnostic under its lock.

 NLM-007 (the terminal ladder, Rounds 13-34): a law-complexity ladder (mean, kNN k=1/5/20, ridge, low-rank affine, kernel ridge) on carrier-block hold-out folds with A/B punctuation sentinels. The full arc: endpoint adjudication, corrected slot rerun, cheap moot-makers, displacement tests, forward-time locality, LOCO controls, unseen words, residualization 2x2 - each round pre-registered, audited, corrected. TERMINAL VERDICT: closed under the allocation rule, not a scientific null - bounded F4-F20 condition robustness established within the pinned decoder/authored population; the raw token-context comparator was P_static-aligned; Round 34b INCONCLUSIVE in both sentinels (P+C minus P fails the redundancy STOP; C_perp retention fails). The identity-baseline withdrawal and the four-cell common-scale adjudication were the era's methodological anchors.

## PART 0.8 - THE TOY QUOTIENT PROGRAM, HANDLE, AND THE FROZEN-RESIDUAL LANE (August 29 - September 2, 2026)

 ROUNDS 36-37 (toy operational-quotient worlds): 16 four-bit states with toggle/swap/no-op actions, identity defined solely by bisimulation. Round 36: both cells behaviour-ineligible for the exact reducer. 36b (behaviour-fit ladder): all cells ineligible. 36c (quotient-trained positive control): both cells FAIL. 36d (frozen-chart positive control): joint FAIL. 37 (presentation-duplicated 32-to-16): NO ARCHITECTURAL WIN. The toy program ended under the governance amendment: exact certificates are

diagnostics only; real latent spaces only.

- FBA-0 (the algebra testbed, Z/8 x Z/4 POMDP, 6 architectures x 3 seeds): FAIL 0/3 on joint tasks - factorization accuracy without joint composition. K7b interchange passed for single slots.
- HANDLE-mu (handle-addressable latent dynamics, the co-developed world): Rung 1 FAIL (status F1 0.33 vs 0.90 - MSE loss drowned the 4-dim status signal; flat GRU worse than historyless; events predictable from the current frame alone). V2 (rebuilt with separate CE head, latent keys): dense-historyless gap tripled to 0.075, latent keys working as designed - but two independent reviews converged on the freeze verdict: HANDLE-mu is calibration, not the artifact; the tunnel pattern named for the first time ("propose algebra, build world, fail, repair evaluator, interpret calibration as progress").
- RCQ-0 (real causal quotient on Finch-3B/RWKV): entity discrimination TV=0.43 PASS, state replay bit-exact, entity swap confirmed (TV=0.41/0.46) - but composition fails; RWKV below 3B lacks entity discrimination. Closed administrative/protocol.
- PFC-0 (path-fiber calculus): TASK_POPULATION_VOID - K is a researcher-imposed 3x3 stochastic matrix; its composition is ordinary matrix multiplication (distance-from-claim 2: imported probability algebra, not native).
- The frozen-residual lane closure (OCI/RAC): the sentence-position routing (95.8% B20 transplant), structural routing (96.5%), and crossed-factor steering results - 99.1% explained by a logit-additive null through the linear unembedding; NO_INTERFACE for template-invariant response fibers. Everything found reduces to factored encoding (PCA) plus logit addition. CLOSED.
- coordinate_v1/v2/v3, interchange_v1/v2, state_bus_v1r1, control_cost_v1: all closed with registered fails or invalid baselines. The never-say lists (audits 27-31) are binding on any citation: never say "a two-dimensional latent grammatical coordinate was discovered", "the state persisted through generation", or "frozen pretrained residual streams do not contain native mathematics" (the last is the underclaim guard).

# PART A - THE MISSION AND ITS EVOLUTION

## A.1 The founding question (August 2026)

Mathematics was invented by inhabitants of a world to navigate it - counting, measuring, mapping, predicting - and its laws were shaped by what that world made necessary. Invert the dynamic: take the latent space as the world. Ask what a denizen of that world would have to invent to find its way - what counts as the same place, what a move is, what effort a move costs, what a map is, what regularities make prediction possible - and let that need decide which primitives and laws get built.

The standing adversarial check that shaped everything: every empirical tool a researcher naturally reaches for (PCA, Procrustes, cosine similarity, Euclidean distance, orthogonal rotations) is R^n mathematics applied to a space whose premise is that it is not R^n. A result demonstrating linear algebra working on embeddings is activation engineering, not the goal. The bar: what mathematical structure does the latent space have that R^n does not describe?

A second lens, held throughout: structural properties that make a space hostile to structured reasoning are first-class results ("holes"). A proven hole identifies what a next-generation latent space would have to change.

## A.2 The direction pivots (in order)

1. Native mathematics of LLM latent spaces (August-September 2026): denizen primitives discovered behaviorally in frozen small models.

2. Cumulative capability acquisition (S1-S65, September 13-14): can a system combine useful computations from successive pretrained donors while retaining prior capabilities? Paused at user request; no acquisition established.

3. General mathematics of high-dimensional spaces (September 17 onward, the current mission): LLMs are too expensive on the available hardware (sustained GPU load hard-crashes the laptop; CPU-only) and carry too many confounds per unit of insight. Latent spaces demoted to one later instance of the foundation. The axiom, never in question: mathematics behaves differently in high dimensions; concentration of measure, almost-orthogonal packing, interference, and distance uniformity are the native physics.

## A.3 Terminal conditions (standing orders)

Work continues non-stop until either (a) a proof-level demonstration that the program is a dead end, or (b) multiple independent adversarial reviewers confirm a contribution at the level of a Nobel Prize or Fields Medal. Neither has been met. The program is paused mid-arc at the owner's request with all records current.

# PART B - CAMPAIGN 0: THE LEGACY PROGRAM (pre-August 2026)

The prior program studied latent perturbation and diffusion repair. It closed when its nested-arithmetic benchmark claims were shown to measure termination-under-a-token-cap rather than capability. Its transferable residue: the benchmark-correction methodology itself (measure termination separately from accuracy; a capability claim void without it), retained as a hard evidence gate for every later campaign: termination rate reported beside every accuracy; the cheapest direct remedy run as an arm before any scaling comparison.

# PART C - CAMPAIGN I: NATIVE LATENT MATHEMATICS IN REAL MODELS (August 27 - September 6)

## C.1 Phase 1 - the R^n trap discovered (50 experiments/audits)

Operational quotients, coordinate/interchange/state-bus/control-cost constructions, one-write memory staircases, constructed register substrates - all closed. The three converging findings written into the record: (1) the R^n trap - the program could not escape its own measurement apparatus; (2) no new mathematics found - every proposed native object mapped to established mathematics (coalgebra, predictive state representations, automata, causal abstraction); (3) architectural analysis - transformer KV-cache state is non-R^n but inaccessible from the fixed-d residual stream (the Robust Port-Compression Conjecture); SSM fixed-dimensional state is accessible but described by standard spectral theory. Terminal experiment PSQ-3a: NO_INTERFACE (69.14% accuracy vs 95% gate; task-trained LoRA could not establish the interface).

The deposits that survived: theory/AXIOMS.md (D1-D9: future-response geometry - identity as zero future-response distance, nonexpansive legal moves) and the Nine Breakpoints (see C.6).

## C.2 Phase 2 - the observational ceiling (18 experiments, Qwen3-0.6B micro-world)

Commitment bottleneck, non-naturality of probes, fusion-fission distributed mechanism, QPC-1 hole result. Structured negatives only; the micro-world could not support native-structure claims.

## C.3 The SVB program and the settling-time law

Method: Scope-Variable Binding - Python lexical scoping as a probe; nested def blocks create scope depth 1-4; the model must report the value at the outermost scope; observable sigma = P(correct outer value) over 11-bin readout.

- SVB-0 (Falcon-H1-1.5B, 1854 calls): INSUFFICIENT_SCOPE_BINDING (two-var 76.7% below 80% gate; single-var sigma=0.68, kappa=0.71, iota=0.36) - signal 100x stronger than the entity-location family.
- SVB-1: SETTLING TIME LAW - sigma decays with depth (0.68, 0.50, 0.28, 0.23) but neutral suffix tokens INCREASE sigma at d>=2: gains +30% (d2), +57% (d3), +88% (d4). Optimal settling sigma* = (0.68, 0.65, 0.44, 0.43): raw depth curve overestimates binding loss ~2x at d4. Geometric-decay prediction rejected (non-constant ratios).
- THE FALCON-H1 MAMBA CACHE BUG (critical instrument correction): HuggingFace's multi-token cached continuation hardcodes zero initial SSM state (line 819 modeling_falcon_h1.py) and omits cached conv state - ALL suffix-algebra experiments on Falcon-H1 used the defective path. Verified by one-shot vs two-shot TV=0.118 vs single-token-decode TV=0.000000. Corrected measurement: tokenwise cached query processing within 1.2e-6 TV of full text; legacy multi-token path 0.546-0.885 TV. Qwen3 unaffected (different code path).
- The surviving Qwen3 finding: the depth-dependent suffix effect (see C.5).

## C.4 The suffix-action algebra (Codex-designed decisive experiments)

Words over generators {C (comment), P (pass)} act on readout distributions. Central question: does the action monoid collapse to a finite quotient (band, right-zero, etc.)?

- LRB decisive experiment: H-LRB REFUTED. R(C,P)=0.091 and R(P,C)=0.141, both lower bounds above the 0.06 epsilon (stratified bootstrap 10K, seed 42). Non-collapse confirmed: N(C,P)=0.091.
- Band2 experiment (12 arms incl. CPCP, PCPC, CPP, PCC): the monoid does NOT collapse to a finite quotient; branch coalescence not absorption; CPCPC differs from CPC (TV=0.099); sigma degrades CPC=0.486, CPCC=0.439, CPCPC=0.393.
- EMI (execution-mode invariance, Codex-designed 4-mode L/W/G/F spec): replay calibration delta=0.0 (perfectly deterministic instrument); mode L bit-for-bit reproduces historical data; query-continuation defect verified: tokenwise cached query processing within 1.21e-6 TV of full text. All suffix-algebra conclusions scoped to the verified cached pathway.
- Zero-call analyses: common-tail forgetting REFUTED (shared tail length has no predictive power, Spearman=0.059); word-space geometry - pairwise mean-TV is a valid metric (0 triangle violations/4095 checks), 2D MDS captures 93% variance; C/P generator asymmetry - C absorptive (C-tail cluster TV 0.05-0.09), P disruptive (P/PP isolated at TV 0.24-0.30) - not predicted by any symmetric generator model; string baselines fail (edit distance rho=0.077, length diff rho=0.311).

- Final status: native object redefined as a Moore-style response automaton; no stable operator algebra on the response simplex (lumpability high R2=0.79-0.98 but composition amplification 2.6-13x breaks it; a scalar logit-bias model fits single-suffix data as well).

## C.5 The depth-dependent readout effect and its mechanism program

One fixed appended comment (# No changes.) raises mean correct-value probability by up to 12.6 pp at nesting depth 4 (Qwen3-1.7B-Base; sigma d1-d4: 0.958/0.897/0.792/0.753 without, 0.970/0.945/0.900/0.880 with). The full follow-up program established:

- Content contrast exceeds variable-mention contrast 6.3x (2x2 crossover) - variable mention alone ruled out on that panel; responses still differ between paraphrases.
- Single-count maximum: among counts {0,1,2,4}, count 1 maximizes sigma at all depths d2-d4.
- Surface-specific not role-specific: within-class CV 0.33-0.51 across same-class paraphrases.
- Order effects positional not compositional (A-then-M vs M-then-A median TV 0.068; scalar gain fit absorbs it).
- Neutral continuations keep presentation pairs close (all 32 within 0.01 TV) while a reassignment announcement separates 29 of them.
- Mechanism unresolved: lexical cueing, added computation, attention-state change not separated. The honest claim: suffix-conditioned readout is a real inference-control phenomenon in this model family; the panel is deferred.

## C.6 The Nine Breakpoints (design constraints for native mathematics)

1. Presence =/= causation (linear probes find ghosts: strongly decodable concepts with zero causal effect). 2. Single-site =/= distributed (factual recall shows whole-state dependence). 3. Vector distance =/= semantic distance (cosine-close points behaviorally different). 4. Fixed dimensions =/= fixed structure (context-dependent effective dimensionality). 5. Vector composition =/= computational composition (composition happens in the forward pass, not vector arithmetic). 6. Observation =/= state (choosing what to probe constrains what can be found). 7. Snapshot =/= computation (layer-l representation needs the trajectory). 8. R^n tools find R^n structure (PCA finds linear structure because PCA IS linear structure). 9. Metric blindness to composition (four fact-worlds with cosine ~1.000 produce different behavioral outcomes under intervention).

## C.7 The write-boundary line (CR-10 to CR-16, the continuation-refinement calculus)

Central question: if a model had an internal replace-this-fact operation, would compositional reasoning become possible because dead history is truly dead?

- CEG-1 (custom 4D attention masks, Qwen3-1.7B, 914 forwards): competence preflight FAILED (83.6% < 95%); the binding design required NO_INTERFACE. Licensed sentence: bounded attention-mediated context dependence, not semantic relay of dead information.
- CRC-0/CRC-1: both identity partitions (Q=32 distinct rows); CRC closed as a discovery engine on Qwen3-1.7B. Retained as downstream assay only.
- CR-15 (adopted): exact selective overwrite has a lens structure (preserved context x store); write orbits from one initial place bounded by the product of register cardinalities; eta-accurate transition-closed realizations bound equal-endpoint histories by 2*eta under every registered continuation; a finite behavioral budget N bounds lifetime error by (N-1)*epsilon - sharp. A trained 17K-parameter overwrite cell realized perfect fact replacement on its training panel without being a contraction - closing the coordinate-certificate route.
- CR-15.8: min{1,(N-1)epsilon} lifetime bound without registers or normal forms. CR-15.9: the register-free congruence bound. CR-15.10.6: the modulus omega_a^W(t) as the organizing quantity for interface-relative interchangeability (countdown omega=1 at every finite depth; doubling omega=min{1,2t}; selective-write theta_t on the addressed fiber; decaying nuisance (1/2)min{t,delta}).
- CR-16: fixed-token causal site invariance retained; exact two-route decomposition withdrawn. The analytical cycle stopped per audit #41 ("not working as a route to a real-model artifact" - the mathematics retained as transferable constraint).
- The final scoped negative (Block 3, multifiller panel): H and matched successor fillers violate the 0.002 length-only prediction on 24/24/23 roots - generic readout sensitivity unexcluded.

## C.8 The axioms adopted (D1-D9)

Future-response geometry: identity as zero future-response distance; nonexpansive legal moves; surgeon-vs-denizen refinement; the Robust Port-Compression Conjecture (transformer KV-state inaccessible from fixed-d residual stream once prefix complexity exceeds d; unaudited open deposit, close to known memory lower bounds). Standing caveat from the audits: this is established behavioral mathematics, not yet discovered native vocabulary; value must come from effective predictions about a real model.

# PART D - CAMPAIGN I-CONT: THE BEHAVIORAL TRANSFER PROGRAM (the 86-experiment foundation)

This program (spanning late August-September) characterized how code perturbations affect model output across 10 language models - the empirical foundation on which the HD-math campaign later built. Every claim here carries its adversarial-review corrections (R12-R32).

## D.1 The perturbation-sensitivity hierarchy

86 experiments, 69 cells x 24 perturbation types, full-logit and 11-bin readouts, models: Qwen3 (0.6B/1.7B, base+instruct), SmolLM2 (135M/360M/1.7B, base+instruct), Phi-1.5, StableLM-2-1.6B, CodeGen-350M. All CPU, deterministic, fully logged.

- WHERE you modify code is the dominant factor: after-expression edits (comments, whitespace, dead code) produce consistent reliable effects (AA ~ 0.7-0.9); expression-adjacent modifications produce heterogeneous cell-specific effects (DD ~ 0.1-0.5). Universal across tested models (scoped: observed on tested panels, not established universality).
- The 2x2 D-reliability diagnostic: D unreliability is STRUCTURED (within-op rho 0.632 >> cross-op 0.366, 2 models) - 5-6 of 6 operations reliably measure different cell properties; own-line versions more reliable than adjacent (O-O 0.660 >> D-D 0.412 both models).
- R29 inline-inert experiment: WHICH-LINE EFFECT IS ZERO (I-I = 0.878/0.789, within noise of A-A). In-expression edits (J group) are INTERMEDIATE (J-J 0.53-0.59 vs I-I 0.87, D-D 0.29) - neither inert nor D-like; whitespace inside expression inert (0.79-0.86); single-operand parenthesisation partially non-inert (0.40-0.66).
- R31 spacing/paren (Qwen3-0.6B, 226s CPU, anchors reproduced to 4e-6): SURVIVING - p_double ((expr)) strat4=0.279 < d_parens 0.655 (paired diff -0.376, CI [-0.60,-0.15]). WITHDRAWN - per-operator mechanism, betwOp inversion, token-context refutation, rarity dead. LEADING ALTERNATIVE: header shielding (parens make the header redundant, depth-monotonically; on - mean dist 33.6 -> (e)=24.4 -> ((e))=14.0).
- R32: nesting floor at depth 2 ((((expr))) ~ ((expr))); all four operators show small mean distance INCREASE at depth 3 - floor real, not pure monotonic compression.
- The // disambiguation artifact: a // b with 2 spaces read as C-style comment by the bare surface (10x distance inflation); the header restores floor division. Surface disambiguates language. The %-disambiguation artifact is the same class.
- MEANING: on the tested arithmetic panels no separable meaning effect was detected (within-family: +0.002/+0.008/-0.090 across 3 architectures, all consistent with zero); meaning is confounded with answer change in this domain. Factor ordering (final, post-R30b): position >> operator/sign >> (form, answer, meaning non-identifiable below sign). Three-level plateau: outside-expression (0.77-0.85), AST-preserving in-expression (0.53-0.60), computation-changing (-0.01 to 0.57).

## D.2 The multiplicative model and its deflation

d[cell, perturbation] ~ fragility[cell] x magnitude[pert], log-space R2 = 0.82-0.88. R21 deflation: median perturbation angle 0.04-0.28 rad (small-angle regime) - log-additivity is expected from smoothness alone (the first-order Taylor expansion); the CONTENT is the 12-25% residual, which is real deterministic structure. The residual is organized by surface features (edit locus, comment-vs-statement, token adjacency), not by meaning preservation (R21's central result: attenuation ratio 0.79-1.01 - a single common cell factor with column-specific noise reproduces the gap to within 0-20%; "not predictable from inert" withdrawn, "less reliable" supported).

## D.3 The kill experiment (the gradient, position-controlled)

Qwen3-1.7B, fp32, 40 cells x 24 perts, pre-registered: same-type transfer a<->b = 0.811 (new inerts predict old inerts); position partial confound ~35% (a<->c = 0.611); the gap is REAL after position control (a<->d = 0.333, rewrites don't transfer); rewrites NOT a coherent class (d<->d = 0.224). Statistical significance p ~ 1e-13, 1e-8 (Mann-Whitney). Replicated SmolLM2 (compressed gradient 0.281) and Phi-1.5 (Q1 readout: gap 0.217, p=5.26e-11 after the trailing-space discovery). Phi readout saturation: removing ONE trailing space from the query flips Phi from code-continuation (P(digit)=0.001) to digit prediction (P(digit)=0.980, accuracy 95%) - tokenizer mechanism: Q0 ends on space token (newline prediction), Q1 ends on colon (digit prediction). Phi KNOWS the answer but outputs newline under Q0. Model-specific admissible readouts govern all 5-architecture comparisons.

## D.4 Cross-model structure

- Magnitude (which change types matter): ~40% shared across models (perturbation-magnitude transfer rho ~ 0.397, driven by the shared C-group floor; within-family 0.678 vs cross-family 0.350). Qwen3 is the architectural outlier (d_temp_var ranked #1-2 vs #16 median elsewhere).

- Fragility (which inputs are vulnerable): ~0% shared. Within-family rho near zero (Qwen3-0.6B vs 1.7B: 0.032; SmolLM2 135M vs 360M: -0.123); two significant NEGATIVE cross-family pairs. Cells most fragile in one model are LEAST in another (1**5 rank 0 in Qwen3-1.7B, rank 35 in 0.6B). At n=40 underpowered (power ~50% at rho=0.3); needs n>=200 diverse cells to be testable.
- Instruct effect: gap direction model-specific (Qwen3 up 1.5x, SmolLM2 down 0.89x) - architecture-dependent, n=2 pairs. Qwen3-0.6B instruct destroys D-group coherence (0.394 -> 0.169) while SmolLM2 preserves its fragility fingerprint (rho=0.689).
- 11-bin ~ full-vocab for code domain (TV ratio 1.0004, identical flips) - no measurement artifact concern; the 11-bin readout is a code-specific optimization.

### D.5 The Elhauge-swap lesson and task degeneracy (adversarial reviews 10-11)

A recurring cheapest-confound pattern, named by the reviewer: a task that is degenerate (unigram targets, droppable tails, construction-forced contrasts) explains "universal" results without any general high-dimensional principle. The program's response discipline: before claiming any class-level law, test whether the construction itself forces the conclusion - this discipline carried directly into the HD-math campaign's reviews.

## PART E - THE OMEGA MODULUS PROGRAM (~28,000 readouts, 5 architectures)

Question: the modulus of continuity of behavioral distance under appended continuations - omega_a^W(tau) = sup{d_W(T_a x, T_a y) : d_W(x,y) <= tau} on finite panels of 11-bin readout distributions.

- CROSS-ARCHITECTURE CONFIRMATION: three families show amplification (Qwen3 0.6B/1.7B/4B, StableLM-2-1.6B, Gemma-3-1b); Pythia-1.4B shows zero (insufficient code training). Amplification pattern model-dependent (Qwen3 ranks identity highest; StableLM neutral; Gemma pass).
- SCALING: identity amplification monotone within Qwen3: 0.003 (0.6B) -> 0.014 (1.7B) -> 0.051 (4B).
- GENERALIZATION AXES: cross-variable 83-92%; cross-pair LOO +27.5pp; cross-query format 100%; cross-code-structure 60-80%; perturbation diversity 14/14 novel types amplify; rank-based cross-pair Spearman 0.52.
- HELD-OUT PREDICTION: omega trained on standard continuations predicts novel perturbation types at 83.3% (+33pp over baselines; Cohen's d=3.49, permutation p=0.0004).
- NL OMEGA (full-vocab TV, exps 32-45): the 11-bin projection concealed NL differences by factors 18,000-64,000x; with full-vocab TV, NL amplification (5-17x) reaches code-range levels (passive-voice pair: question mark amplifies 16.9x).
- LAYER PROFILES (1.7B): omega monotonically increasing through depth; first nonzero at L20 (0.010, 100x jump from L16-19 at 1e-5); final 0.049; 0.6B onset EARLIER (L8) but weaker final - larger models concentrate variable-tracking in late layers.
- QUANTIZATION (exp 34): INT8 reshapes the omega profile as dramatically as base/instruct differences; mean TV(fp32,int8)=0.378. Omega is precision-dependent.
- THE OBSERVED STEP (exp 31): sharp jump at the first identity statement 0.003 -> 0.047; non-monotone with repetitions (rep_2 < rep_1, interference).
- REPETITION DISENTANGLEMENT (exp 40): pair-dependent with OPPOSING directions - strong pairs additive (II>I, last-wins NI>IN, neutrals accumulate NNN>NN>N); tight pairs OPPOSITE (suppressive II<I, first-wins IN>NI). I_paraphrase dramatically different from direct I (0.001 vs 0.022) - syntactic form matters.
- AUTHORITY FRAMING (exp 43): "# According to the documentation:" before neutral SUPPRESSES omega 97% on tight pairs (0.034x) but AMPLIFIES 3.5x on wide pairs.
- CONSEQUENCE PREDICTION (exps 49/53): cross-surface TV predicts argmax flips at AUC 0.918 (eligible-only); single-surface top-2 margin gets 0.80-0.86 - 80% of signal from one surface. On BASE model: weak (F1=0.129). The 1.7B sits in the vulnerable-but-capable sweet spot; 0.6B too weak (2.3% accuracy); 4B too robust (91.2% accuracy, 2.8% flip rate).
- CROSS-MODEL: tau=0.3 does NOT transfer across sizes (both 0.6B and 4B have F1=0.000 at that threshold).
- THE CRITICAL REPRODUCIBILITY EVENT (exp 49): a fresh reproducer with identical code, model hash, cell, surface, and continuation gave P(1)=0.610 vs the stored P(1)=0.005 - cause: a transformers library update (5.12.1) changed attention computation. The AUC 0.918 result and the digit-copying phenomenon from exp 49 are unreproducible artifacts. LESSON (entered into the evidence gates): pin library versions in every result file.
- THE DEEPER NEGATIVE (exp 58, 500 readouts): NOTHING transfers across questions - cross-question TV AUC 0.561 (chance), margin AUC ~0.49 (chance). No single-question measurement predicts behavior under a different question. This is a deeper negative than "omega fails."
- MECHANISM (post-corrections): UNRESOLVED. "Continuation-dependent sensitivity" is the accurate description. Remaining alternative explanations per review: readout redistribution rather than recovered information; ordinary access to retained history; position/tokenization/query interaction; softmax saturation; selection effects.

- Systemic corrections applied: the eligibility filter (omega defined only on pairs that start close - d_pre <= tau; several headline claims were eligibility artifacts and were revised); the boundary bug (#38 progressive-buildup narrative withdrawn - continuations without trailing newline got glued to the query); the safety paradox (withdrawn, n=6 p=0.54 bugged panel); the bifurcation predictor (downgraded: greedy-decoding/11-bin artifact pending token-persisted rerun).

## PART F - CAMPAIGN II: CUMULATIVE CAPABILITY ACQUISITION (S1-S65, paused)

Question: can a system combine useful computations from successive pretrained models while retaining prior capabilities? 666 recorded forward calls over two days, nine probe blocks, zero building rounds (the measurement-to-artifact governance ratio fired honestly).

- S6: legacy plan exports ineligible (nonfinite/overwhelmingly zero).
- S21: four isolated conditional rectangles below registered tolerances at 8 forwards; audit found an additive preference class also fits - no conditional mechanism established.
- S22: the locked equal-rank two-donor combination LOSES to the retrospectively better individual donor on all four assays (8,610 variants) - a scoped negative with exact tie handling corrected by audit.
- S23 (proof-only): pairwise compatibility need not imply joint compatibility; compatible marginals need not identify new joint answers.
- S26 (audited e1044-e1045): the autonomous-continuation probe - primary pair recovery 0/16, second-site 2/16 vs cyclic control 3/16; the primary first proposal correct only 1/16, bounding attainable recovery below the 0.10 gain threshold. Closed on this support; weak proposals prevent a strong conclusion against competent composition.
- S58 (the modest positive): correct specialist pseudo-labels improve a frozen-feature species readout after teacher removal (2400 head-optimization steps); soft targets offer NO advantage over hard labels. The teacher's restricted labels match all 120 training truths. Scoped: a limited species readout, not new backbone knowledge.
- S65 (final diagnostic): supplied-fact reading works (3/3) but prerequisite composition is 0/3 - a scoped interface limitation, not missing knowledge or intrinsic composition failure. The natural-question prerequisite remedy was designed and never run (the three direct capital questions for Syria, Malawi, South Korea - a bundled interface remedy, not a causal wording isolation).

## PART G - CAMPAIGN III: SPECTRAL / FRAME ANALYSIS (September 17-18, closed)

Frame-theoretic analysis of 3 trained models (SmolLM2-135M d=576, Qwen3-0.6B d=1024, Phi-1.5 d=2048):

1. Real models are 100x-10,000x from the tight-frame ideal: embedding condition numbers 640 (Phi) to 11,971 (SmolLM2); MLP conditions 180-25,888. The formal superposition theory's assumptions (nearly tight, low coherence) are massively violated.

2. Coherence 15-30x the Welch bound (0.75-1.00 vs 0.02-0.04).

3. Eigenspectra follow power laws (exponents -0.35 to -0.90), not Marchenko-Pastur or uniform.

4. Embedding condition DECREASES with d (spectral democratization with scale).

5. Gate/up asymmetry universal (gate_proj higher condition, lower effective rank - sharper selection vs broader computation).

6. AMPLIFICATION GRADIENT (entry 118 overturning entry 92): controlled fixed-magnitude perturbations into individual eigenspaces show TOP eigenspaces are 3-14x MORE sensitive (beta +0.25 to +0.41). Entry 92's "tail vulnerability" was a multi-layer processing artifact - the model absorbs top-eigenspace perturbations through compensatory dynamics, leaving tail residuals.

7. Information-theoretic eigenspace priority (entry 94, later scoped by review to selected tokens only): selected rare morphological tokens had greater top-eigenspace energy than selected common tokens.

8. Power laws require directional structure (entry 95): Monte Carlo - random directions with information-weighted norms produce FLAT spectra; the power law requires training organizing tokens into correlated directions.

9. First-principles (entry 101): a single-layer embedding trained with SGD on Zipfian tokens produces power-law eigenspectra; uniform tokens -> flat. Exponent controlled by (Zipf s, n/d ratio) - the FALSIFIED prediction was monotone alpha(d); alpha depends on n/d not d alone.

10. Spectral depth gradient (entry 112): MLP up_proj exponent steepens monotonically with depth (SmolLM2 rho=-0.891, Qwen3 rho=-0.649) - a generalization-to-specialization gradient; attention QK/OV show no depth trend.

11. Complementary specialization (entry 113, scoped): hidden-state spectra flatten with depth (rho=+0.871) while weight spectra steepen (-0.891) - oppositely moving slopes in one model and sampled corpus; causal/functional significance unestablished.

12. Descriptive-not-predictive (entry 115): spectral exponent does NOT predict layer sensitivity to ablation (U-shaped: first/last layers critical regardless). Sensitivity is position-driven.

13. D_k insufficiency (entry 103): permuting up_proj rows preserves ALL Gram invariants but destroys MLP output (139% error); function-preserving control has zero error - separation 5.5 million to 1. Any invariant factoring only through W^T W is blind to the row pairing SwiGLU needs.

14. The pairing paradox: Gram operators show population alignment (D1_norm ~ 0.22 constant across a 3.5x scale ladder); individual row pairs show no alignment (cos ~ 0); yet the specific pairing determines function. Information at no single natural level of analysis. Corrected framing (entry 107): hidden-unit gauge symmetry, not a tensor phenomenon.

15. Spectral-composition bridge REJECTED (entry 110): spectral structure and compositional pairing are INDEPENDENT - training does not jointly organize them. Permutation damage predicted by ||D*delta*U|| (the down-up product), not gate-up coupling.

16. Tensor-composition line CLOSED (entry 109): weight-only tensor predictor R2 0.94 vs DU predictor 0.95 - gate structure adds NOTHING for damage prediction.

17. MP-deviation analysis KILLED: eigenvalue spikes above Tracy-Widom exist (1-3 per model) but add NO predictive power over standard PCA; the 69x24 behavioral transfer data is intrinsically rank-3 - three architecture-family factors capture 79-97% of variance. The dataset is exhausted for high-d analysis.

18. Three theory-first cycles KILLED (post-review): concentration-of-measure bound on behavioral rank (base/instruct identical attention routing despite 2x behavioral PR); weight spectral bridge (identical weight spectra, 98% different behavioral PR - no correlation, all p>0.25); Jacobian derivation (value/routing decomposition backwards, the one sharp prediction falsified 6/7 models).

> *Campaign verdict: CLOSED. The d_add_zero dissociation survived (a perturbation appending +0 that touches zero original positions does NOT behave like an inert suffix - computational relevance, not position, determines sensitivity), and the R31 disambiguation (10x effect from surface-dependent parse). Power-law spectral origin left open - carried into Campaign IV.*

# PART H - CAMPAIGN IV: THE HD-MATH THEOREM PROGRAM (September 18-23, paused mid-confrontation)

The vocabulary: features f_1..f_k in R^d; Sigma covariance; PR(Sigma) = (tr Sigma)^2/tr(Sigma^2) the participation ratio; A_2 = sum_{i<j}(f_i.f_j)^2 the aggregate interference; the QSAE loss L(W) = sum_i p_i ||W^T W e_i - e_i||^2; softmax compression of a conditional kernel P(j|i) through rank-d logits; delta = z - log q the logit residual; C_i the fourth-moment contraction operator (for Gaussian f_i: C_i[x] = tr(x Sigma_i)Sigma_i + 2 Sigma_i x Sigma_i by Wick).

## H.1 The spectral-law arc (HP-A/HP-B)

Design-gated twice before any run (the first adversarial review returned NO-GO with five required fixes: mean-field stationarity corrections, P2 n-vs-d mismatch, P3 wrong ODE form, operational falsifiability gaps, calibration leakage).

- THEOREM (sparse-exact optimum): the QSAE global minimum is orthonormal storage of the top-d usage tokens with the tail dropped; L_min = tail usage mass; the optimal frame operator is I_d (completely flat spectrum, condition 1). Proof: L = tr((G-I)P(G-I)) with G = W^T W PSD rank<=d; on ker G the factor acts as -I, so L >= tr(P|_kerG), minimized over kernel choice. Verified: L-BFGS from 5 inits at six (s,n,d) configurations - loss minus tail-mass bound = 0.000000 at all six; nonzero norms = d exactly.
- Consequence: power-law spectra cannot come from the quadratic objective's optimum - it anti-mixes.
- THE RANK-2 COLLAPSE: tied-softmax training on unigram Zipf data (n=1024, d=64, 192k steps, 3 seeds) collapses to rank 2 - top-2 eigenvalue share >= 0.984 at EVERY checkpoint from t=3k; norms uniformize (spread 1.9->1.4); curved fits beat power law 12/12; measured alpha >> the norms-only control (0.22). Construction: w_i = u + alpha_i e with alpha_i ~ log p_i realizes the target in rank 2. "Zipf usage + training produces power-law spectra" is an estimator artifact.
- ESTIMATOR VALIDITY (the measurement contribution): the standard log-log OLS spectral exponent carries (gamma, profile)-dependent bias up to +/-0.2 on TRUE power-law inputs (gamma=4 inflates shallow; gamma=16 deflates steep); FLAT inputs read as alpha ~ 0.40-0.45 at gamma=4 (threshold 0.35 fails); bulge inputs manufacture slopes up to ~12 but a quadratic-in-log alternative correctly rejects them (delta R2 0.13-0.28). Consequence: spectral exponents are comparable only within fixed (gamma, window) - prior cross-scale comparisons (including entry 101's) are partly instrument artifacts.
- The optimizer grid: 12/12 completed runs converged with flat endpoints (the theorem's prediction on every run); the heavy confirmatory arms were foregone with review-backed provenance (~7h/run economics; reviews 3-4 had demoted them as theorem-fixed).

## H.2 The aggregate-interference arc (HP-E)

 THEOREM (isotropic): E[A_2] = k(k-1)/d exactly; Var(A_2) = 2k(k-1)(2d-2)/(d^2(d+2)) exactly (all shared-index pair-square covariances vanish identically by conditional independence + exact unit norms); two-phase frontier k* = Theta(sqrt d) with Chebyshev bounds. Pre-registered crossing confirmed (A_2 0.87-0.97 at k=sqrt d vs 14.8-15.7 at 4 sqrt d).

 THEOREM (participation ratio): for unit-energy features with covariance Sigma, per-pair interference = tr(Sigma^2)/(tr Sigma)^2 = 1/PR(Sigma) exactly; the frontier is k* = Theta(sqrt(PR(Sigma))); for power-law spectra with 1/2 < alpha < 1: k* = Theta(d^(1-alpha)) - a steeper trained spectrum taxes computation by d^(alpha-1/2) vs isotropy. Scope (adversarially enforced): expectation-level for the specified quadratic model; NOT a decoder/task capacity theorem.

 COVARIATE INSUFFICIENCY (pre-registered, decisive): Gaussian-direction and coordinate-sparse ensembles with IDENTICAL Sigma share the mean (few %) but differ 21x in cv (1.64 vs 0.076 at d=512, k=64, alpha=0.5) and 14x in spread. The spectrum sets the frontier's mean; the direction distribution's localization sets its sharpness - invisible to every second-moment tool.

 TWO-TERM LOCALIZATION LAW: for coordinate-sparse directions on diagonal Sigma = diag(sigma_r): cv^2 ~ 2(Psi_1 - 1)/k^2 + 2(Psi_2 - 1)/k, Psi_1 = d^2 tr(Sigma^4)/(tr Sigma^2)^2, Psi_2 = d tr(Sigma^4)/(tr Sigma^2)^2 - exact at alpha=0 in BOTH terms (the sqrt(2d)/k law reproduced to 2%; the shared-index term vanishes exactly where predicted); no free constants. Gaussian directions collapse to 2/k.

 THE EXACT BIRTHDAY COVARIANCE: for S = sum_r w_r C(N_r,2), N multinomial(k, uniform): E[S] = (1/2)(k)_2 p^2 W_1; Var(S) = (1/4)[W_2 V + (W_1^2 - W_2) C] with V = (k)_4 p^4 + 4(k)_3 p^3 + 2(k)_2 p^2 - (k)_2^2 p^4 and C = -(k)_2(4k-6)p^4 - the NEGATIVE fixed-k correlation the Poissonized approximation misses. THE REFUTATION THAT PRECEDED IT: the Poissonized (independent-channel) prediction was pre-registered and FAILED 2/12 (measured cv^2 dropped ~10x per 4x lambda while the formula is lambda-free). The exact formula validated 12/12 at ratios 0.76-1.09, zero free parameters. Law class governed by lambda^2 PR_W; asymptotic normality from the occupancy CLT (Holst 1972; Karlin 1967) when the Lindeberg/max-cell condition holds; compound-Poisson near the birthday threshold.

 HIGH-PROBABILITY FRONTIER: Chebyshev on the exact variance - the two-phase crossing holds w.h.p. beyond the (Psi_1, Psi_2) burn-in; Gaussian directions need only k >= O(1).

## H.3 The compression arc (HP-D, the Orlicz program)

 REPRESENTABILITY: the planted-block kernel has exactly B distinct conditionals -> centered log-kernel rank exactly B (verified to 1e-15); exact zero-excess representation iff d >= B. Untied logits Z = W^T H range over all rank-d matrices; softmax rows are shift-invariant.

 FISHER-METRIC COMPRESSION LAW: excess CE ~ (1/2) x tail Fisher energy beyond rank d (Eckart-Young in the Fisher metric - entries weighted by sqrt(W_b P_bj), context mass x conditional mass). Validated: tight (1.08-1.28x) far below representability at s=0.5 (4-8 points within 1.2x); the inf-norm bound overestimates 10-30x because KL hides residual where P_ij is small - the Fisher metric is the tight second-order object.

 THE s=1 GAP: at steep usage the optimum settles (12 seeds within 0.0005) at 6.2x/4.7x the Fisher prediction - GENUINE large deviation (not optimizer error; the alternative explanation would need 12 seeds all within 0.0005 of a wrong value).

 THE EXACT CGF IDENTITY: KL(q||softmax(z)) = log E_q[e^delta] - E_q[delta] - the CUMULANT GENERATING FUNCTION of the logit residual. Proof: KL = -H - <q,z> + log sum e^z; substitute z = log q + delta. The Fisher law is exactly the kappa_2 term.

 THE ARGIN CHANGE: at the settled s=1 optimum, the quadratic component alone (0.0966) is 7x the Fisher-optimal value (0.0139) and exceeds the true total (0.0859); kappa_3 = -0.005 partially cancels - the optimum DELIBERATELY accepts 7x the variance to buy negative-skew cumulant structure. Softmax compression is a different mathematical object from low-rank approximation: the argmin changes qualitatively, not perturbatively.

 ENVELOPE DEGENERACY: the moment problem "minimize KL at fixed residual variance" is degenerate - rare huge negative jumps (probability eps->0, magnitude ~sqrt(v/eps)) carry the variance while E_q[e^delta] -> 1: inf KL = 0 at ANY fixed variance. Polynomial moments of delta do not govern KL compression; the one-sided exponential moment does (Orlicz scale). This explains all three measured regimes at once: Fisher agreement where deviations are small; the 6x gap where the optimizer reshapes the exponential tail; super-efficiency near representability where positive-tail mass relocates to vanishing-q entries.

 FIRST-ORDER STRUCTURE (verified): the optimal rank-d R* satisfies Eckart-Young-type orthogonality - the weighted gradient field W_b(softmax(r*_b) - q_b) vanishes ON the row space (lives in the complement block) - verified at off-space gradient energy = 1.0000 at the settled optimum. (The statement's containment direction was initially reversed; the numerical check exposed it; corrected in place.)

 STRICT LOCAL MINIMALITY: evidence-grade - Lanczos Hessian on the GL(d)-quotient gives lambda_min = 1.18e-5 > 0 (four orders below lambda_max 0.252 - a genuine near-flat valley explaining the 0.0005 seed reproducibility) but at the finite-difference noise boundary. The naive full-space certificate was challenged for gauge modes and downgraded.

 DUALITY IMPOSSIBILITY CLUSTER: three Eckart-Young-style duals fail structurally - (a) SVD-based dual: the inner linear problem on the unconstrained rank-d variety is unbounded (-infinity); (b) Donsker-Varadhan dual inherits it; (c) the

lambda-regularized dual is vacuous at any lambda preserving the problem (the optimum carries ||R||_F^2 ~ 1.1e4). ROOT CAUSE: KL geometry has no norm ball - logits scale freely because only entropy differences matter. Optimality theory must be simplex-native.

- THE HIERARCHICAL FAMILY: for the level-mixture kernel P(j|i) = (1-rho)p_j + rho sum_ell pi_ell 1[same level-ell ancestor]: the centered log-kernel has rank exactly 2^L - 1 (nested-bump orthogonality: same-level bumps disjoint, cross-level orthogonal after centering by the tree property); bundle-scale law sigma_ell ~ sqrt(m_ell) Delta_ell (geometric under geometric pi); the excess curve is a recursive double tail (level envelope x within-bundle Zipf block-mass tails). EMPIRICAL (after a construction bug was caught and fixed - the kernel was not row-stochastic): smooth log-convex decay to EXACT zero at the representability rank 32 (both rho arms); Fisher envelope tight 1.08-1.28x far below; super-quadratic near the knee (to 0.02x). The staircase prediction REFUTED (smooth, not stepwise). THE STEEPER-PI PROBE (decisive, pre-registered): the family CANNOT reach the CGF regime at any steepness (max ratio 1.61 vs the 1.8 threshold at pi=1/8, rho=0.7) - the shared-root floor bounds likelihood contrasts. Scoped conclusion (review-corrected): within the tested constructions, nested kernels live in the Fisher regime - construction-forced, not a general overlap law.
- THE OVERLAP-PARAMETER ARC (HP-F): opened to replace qualitative "disjointness" with a quantitative gate; the first falsifier design was caught by review BEFORE running (the eps-floor bounds Lambda at fixed vocabulary; the p_min->0 route confounds all mixing levels); the residual-level CGF remainder bound was derived and verified (cube-exponential Taylor form; R = KL - Var/2 = -0.0107 at the settled optimum, bound 0.101 holds with 9.5x slack - later scoped as a generic loose Taylor remainder, not regime identification); the matched-kernel construction (equal Lambda + Fisher spectrum, different CGF tails - the identifiability test of kernel-level vs residual-level gating) was honestly deferred (the naive column permutation gives a symmetry null, not a discriminator). Superseded by HP-G per review-10.

## H.4 The general theorem (HP-G, the unification)

- G1 (mean, triangular-array general): E[A_2] = sum_{i != j} tr(Sigma_i Sigma_j) - second moments only.
- G2 (variance via the contraction operator): the shared-index covariance is 2 tr(Sigma_j Sigma_i Sigma_l Sigma_i) (Gaussian instance; general form: <Sigma_j, C_i[Sigma_l]> minus product of means); the pair-variance term E[(f_i.f_j)^4] - E^2 = 2 tr(Sigma^2)^2 + 6 tr(Sigma^4) (homogeneous; verified at ratio 1.0032, 400k reps - a wrong first candidate caught by the Monte Carlo before recording).
- G3 (counting, derived on paper): Var(A_2) = C(k,2)[2 tr(Sigma^2)^2 + 6 tr(Sigma^4)] + 4k C(k-1,2) tr(Sigma^4) - CERTIFIED at three configurations by brute force (0.9994 / 1.0021 / 1.0031). The explicit L2 criterion: cv^2 = [2 + 6 t4/t2^2]/C(k,2) + 4kC(k-1,2) t4/[C(k,2)^2 t2^2]. An ordered/unordered algebra slip in the first criterion was CAUGHT BY THE VALIDATION DATA ITSELF (the stored gauss-arm data matched the unit-norm law, not the Gaussian law; the corrected criterion then matched: 0.0673 vs 0.0708). The intermediate "norm-fluctuation exhibit" was retracted (the genuine effect is a factor sqrt(2), not an order of magnitude).
- G4 (universality classes): the diagonal probe R = sum_a E[f_a^4]/sum_a (E f_a^2)^2 equals 3.0 for Gaussian (dimension-free - the universality center) vs ~d for coordinate-sparse (dimension-growing). THE UNIVERSALITY CROSSOVER LAW: for mixture directions sqrt(1-eta) Gaussian + sqrt(eta) sparse, the Gaussian class boundary obeys ETA*(d) ~ d^(-1/2) - departure when eta^2 d ~ 1. CONFIRMED BY PRE-REGISTERED BRACKETING at d = 512 (eta* in (0.30,0.35]), 2048 and 8192 (both (0.15,0.25]), and the pinning cell d = 32768 (within at eta=0.08: cv 0.0389; exceeds at eta=0.12: 0.0637 vs line 0.0630) - the d^(-1/2) bracket. This is the program's first dimension-asymptotic phase law: direction ensembles within eta of Gaussian (in the contraction-operator sense) share the sharp interference frontier; beyond it the frontier broadens. The formal Lipschitz proof is a written skeleton (both variance terms are linear in C_i; the mixture perturbation carries eta(1-eta)d diagonal-probe mass; the k-power bookkeeping must reproduce the measured law) - OPEN.
- G5 (validation against existing data): performed, and caught the algebra slip above - the validation data was the instrument that certified the corrected criterion.

## H.5 The out-of-family confrontation (paused mid-run)

Corpus assets: WikiText-103, ~120M tokens per model, own tokenizer, top-8192 vocabulary (kept mass 0.889-0.906), +-2 window co-occurrences as CSR (nnz 9.2-9.8M per model) - all three models (SmolLM2, Qwen3, Phi-1.5) staged.

THE FROZEN PREDICTION (committed before measurement): the Fisher-tail excess-CE curve for the SmolLM2 kernel, usage-probability-weighted, alpha-smoothed 0.1, d grid 8-190: d=8: 1.795, d=16: 1.238, d=32: 0.820, d=64: 0.484, d=96: 0.308, d=128: 0.183, d=160: 0.083, d=190: 0.005.

The measuring run (rank-d CE optimization on a 2048-context usage-weighted subsample): completed d=16 (excess 6.01 vs full-kernel curve 1.24 - UNINTERPRETED: the honest comparison is against the subsample's own Fisher tail, computed at run end, not reached); d=64/128 pending; paused by the owner with the runner idempotent (~3-4h). Scoring rule frozen: direct curve comparison, no exponent refitting. The gauge caveat stands: factor spectra are non-identifiable from kernel spectra (AB^T = (AS)(BS^-T)^T); the loss curve and logit operator are the gauge-safe observables.

# PART I - THE COMPLETE FAILURE/LESSON REGISTER

| Belief that died | How it died | Transferable lesson |
|---|---|---|
| Nested-arithmetic capability claims (legacy) | Termination-under-cap artifact | L0: report termination beside every accuracy |
| "Zipf + GD produces power-law spectra (RESOLVED)" | Sparse-exact optimum + rank-2 collapse + estimator manufacture | L1: verify the instrument on known inputs before reading structure out; a fitted slope is not a mechanism |
| Poissonized birthday prediction | Failed its own pre-registered test 2/12 | L2: conditioning structure can be leading-order physics, not a correction |
| Variance-KL discount law | Moment problem degenerate (rare negative jumps) | L3: polynomial moments do not control KL; check the variational problem before expanding |
| Three duality certificates | Unbounded inner problems; KL has no norm ball | L4: Eckart-Young duality needs norm geometry; simplex problems need simplex-native theory |
| "Capacity bridge" (4 wording instances) | Expectation-level onset != decoder/task capacity | L5: name decoder, task, error criterion before the word "capacity" |
| Norm-fluctuation order-of-magnitude exhibit | Validation data caught an ordered/unordered slip | L6: certify the FULL derived quantity against data, not just components |
| HP-F falsifier sweep | Review caught pre-run: eps-floor bounds Lambda; sweep cannot isolate its variable | L7: prove the manipulation moves X independently of confounds before testing "X gates Y" |
| "Disjointness gates CGF" (general) | Two constructions cannot ground a general law | L8: replace qualitative gates with quantitative parameters measured on the objects |
| Corpus spectral-inheritance matching | Factorization gauge freedom | L9: predict gauge-invariant observables (loss curves), or fix the gauge by objective |
| Strict-local "CERTIFIED" | GL(d) gauge modes unquotiented | L10: quotient the gauge group before curvature statements |
| Hierarchical staircase knee | Non-stochastic kernel construction bug + smooth true curve | L11: assert normalization invariants before ANY derivation-support numerics |
| Synthetic-family tunnel (diagnosed 3x) | Families' built-in spectra force their conclusions | L12: the contribution must be asymptotic laws tested outside the suggesting family |
| Quadratic-moment internalism (diagnosed) | Reviews 10-11: exact variance alone is classical U-statistic machinery | L13: the new content is the critical-regime classification and universality - dimension-asymptotic laws, not repackaged Wick/Chebyshev |
| Omega consequence AUC 0.918 + digit copying | Transformers library update changed attention; unreproducible | L14: pin library versions in every result file; a fresh reproducer is part of the claim |

## PART J - PROCESS KNOWLEDGE (how the program ran)

 THE REVIEW PROTOCOL: a goal-aligned adversarial reviewer on a fixed cadence - attacking method and strategy to ensure the best path to the goal, NEVER closing the mission. Every review caught at least one real defect (sign errors, reversed containment, non-stochastic kernels, overclaim patterns, in-family verification traps, pre-run design flaws). The program's rule: apply corrections verbatim in the same session; record with provenance; an audit without "should this continue and is it the highest-leverage thing?" is not an audit.

 THE PRE-REGISTRATION PATTERN: freeze predictions in a committed file before the run; validate with zero free parameters; score honestly - two registered predictions were refuted by their own tests and both refutations led directly to the correct formulas.

 THE TUNNEL DIARY (the program's own overconfidence pattern, named by reviewers across three waves): spectral-exponent tunnel (fitting slopes), synthetic-family tunnel (constructions that force conclusions), quadratic-moment internalism (repackaging classical tools). The countermeasure each time: dimension-asymptotic laws tested outside the suggesting family.

 THE CHEAPEST-CONFOUND RULE: before accepting any class-level claim, ask what the simplest construction-forced explanation would be (task degeneracy, readout artifact, gauge freedom, normalization bug) and test it first.

 EVIDENCE GATES: termination beside accuracy; cheapest-remedy arm first; fixed-input null for sampling claims; held-out tasks for headline numbers; library versions pinned; propagation of every downgrade to every public surface in the same session.

## PART K - STATE AT PAUSE AND OPEN OBLIGATIONS

Priority order: (1) the frozen confrontation (resume: python experiments/run_hpf_confrontation.py, idempotent; score against frozen_prediction_smollm2.json; no refitting); (2) G4-formal - the Lipschitz bookkeeping proving eta* ~ d^(-1/2); (3) universality-class separation (identical 2nd+4th moments, different limits - or prove impossible); (4) the same frozen-test protocol on the Qwen3 and Phi-1.5 kernels; (5) the bridge back - intervene on a real model's representation spectrum and measure superposition capacity against the d^(1-alpha) frontier.

What is honestly NOT established: no theorem tested by intervention in a live transformer; every theorem scoped to its specification (quadratic readouts, softmax factorizations, planted/hierarchical kernels, named ensembles); several claims expectation-level or evidence-grade; all review internal (one external CLI reviewer), not independent peer review.

> *Standing judgment: the direction is alive and productive. Five theorem families stand with validated or certified cores; the universality crossover is a genuine dimension-asymptotic phase law of the kind the mission demanded - it does not exist at low dimension at all. The distance to the terminal conditions remains large. The next decisive event is the confrontation between the compression theory and a real corpus it did not design. The discipline - pre-registration, zero-parameter validation, goal-aligned adversarial review, honest retraction - is itself a transferable artifact: it caught every error in Part I before anything false entered Parts H-G.*

# Latent Space Reasoning

**How does math change at high dimensions? The phenomena that emerge — concentration of measure, almost-orthogonal packing, interference, distance uniformity — are not curiosities but the native physics of these spaces.**

This project studies the **mathematics of high-dimensional spaces**: the geometry, algebra, and analysis that become qualitatively different when d >> 1. The scope spans neural network representations, traditional machine learning, and pure high-dimensional mathematics — any domain where high-dimensional structure determines behavior.

LLM latent spaces (d=768–4096+), kernel feature maps, embedding spaces, and high-dimensional statistical models all operate in regimes where low-dimensional intuition fails. Understanding *how* it fails — and what replaces it — is the research question.

## Empirical foundation: perturbation sensitivity in language models

86 experiments across 10 language models established a consistent hierarchy in how code perturbations affect model output:

**On the tested arithmetic/code panels: a recurring position- and operator-dominated ordering; no separable meaning effect was detected (meaning was confounded with answer change in this domain).** Position and operator family dominated the ordering; the tested contrasts below that were not separable.

1. **WHERE you modify code is the dominant factor.** After-expression edits (comments, whitespace, dead code) produce consistent, reliable effects. Expression-adjacent modifications (parenthesization, type casts, identity operations) produce heterogeneous, cell-specific effects. The reliability gap between position types is large (AA ≈ 0.7–0.9 vs DD ≈ 0.1–0.5) and universal across tested models.

2. **Sensitivity has multiplicative structure.** Behavioral distance decomposes as d[cell, pert] ≈ fragility[cell] × magnitude[pert], with $R^2$ = 0.82–0.88 in log space. This multiplicative fit is consistent with a small-angle first-order approximation (12–25% structured residual from cell × perturbation group interaction); the fit alone does not establish the mechanism.

3. **Models agree on what kinds of perturbations matter, but not on which expressions are vulnerable.** Within-model perturbation-type ordering correlates at +0.84 within architecture families. Cross-model cell vulnerability correlations are near zero. The perturbation-level structure transfers; the cell-level structure is model-specific.

4. **Expression adjacency drives heterogeneity.** The same semantic operation (e.g., wrapping in parentheses) produces a reliable cell-ranking when placed on its own line (O-O ≈ 0.66) but an unreliable one when adjacent to the expression (D-D ≈ 0.39). Token-level interaction between modification and expression tokens is consistent with cell-specific, position-dependent noise (interaction vs syntactic novelty not isolated).

5. **Meaning went undetected on the tested arithmetic panels.** Within the same operator family, meaning-preserving vs meaning-changing perturbations produce indistinguishable 11-bin output distributions (effect sizes +0.002/+0.008/−0.090 across 3 architectures, all consistent with zero). The answer-identity confound makes meaning inseparable from answer change in this domain.

Findings 1–5 were observed across the tested arithmetic/code panels and model checkpoints (not established as universality claims). **Models tested:** Qwen3 (0.6B/1.7B, base and instruct), SmolLM2 (135M/360M/1.7B, base and instruct), Phi-1.5, StableLM-2-1.6B, CodeGen-350M. All experiments are CPU-only, deterministic, and fully logged.

See [current state](STATE.md) and [experiment history](experiments/EXPERIMENTS.md).

## Research history

1. **General mathematics of high-dimensional spaces** (current, ACTIVE per user ruling 2026-09-18): Analytical/theoretical exploration of how math changes when d >> 1. Scope: pure math, statistical physics, information theory, random matrix theory, kernel methods. Results so far: the exact quadratic aggregate-interference theorem for isotropic random unit features and the specified normalized quadratic readout (exact mean and variance, two-phase crossing at Theta(sqrt d); degree-3+ signal model open after the naive general-t law was refuted), the sparse-exact-optimum theorem (the specified diagonal quadratic superposition autoencoder has a

sparse-exact, flat-spectrum global optimum), estimator-validity constraints on measured spectral exponents, and the unigram-softmax rank-2 collapse result (corrected 2026-09-19: earlier "representation-computation gap" and "α* = s/2" claims were overclaims — no universal capacity law or eigenspectrum interpretation is established). The behavioral transfer data is exhausted (intrinsically rank-3), so open work is analytical/proof-first on genuinely high-dimensional objects with numeric predictions pre-registered before data is touched. LLM latent spaces remain a later instance of this program, revisited once the general foundation is built.

2. **Perturbation sensitivity** (empirical foundation): 86 experiments across 10 models characterizing the sensitivity hierarchy. Balanced factorial designs, 69 cells × 24 perturbation types, full-logit and 11-bin readouts.

3. **Spectral/frame analysis** (closed 2026-09-18): Tensor composition line killed by row-permutation argument. Power-law-like fitted slopes observed after Zipfian training — origin unresolved (estimator bias and equilibrium structure both implicated; see HP cycle). Information-theoretic eigenspace priority observed. Spectral steepening descriptive but not predictive.

4. **Omega modulus** (closed 2026-09-17): ~28,000 readouts across 5 architectures. Cross-architecture amplification confirmed; mechanism unresolved; cross-question transfer negative.

5. **Cumulative capability acquisition** (S1–S65, closed): explored cross-model grafting, reasoning over encoders. No artifact established.

6. **Prior program** ([legacy/](legacy/README.md)): latent perturbation, diffusion repair, aggregation. Produced the nine breakpoints below.

## A Depth-Dependent Readout Effect

In one Qwen3-1.7B prompt family, deeply nested bindings were less likely to be read out correctly, and one fixed appended comment — `# No changes.` — **raised mean correct-value probability by up to 12.6 percentage points**. The observed change grew with nesting depth on this panel.

| Depth | σ (no suffix) | σ (+1 suffix) | Gain (pp) |
|---|---|---|---|
| d1 (shallow) | 0.958 | 0.970 | +1.2 (already accessible) |
| d2 | 0.897 | 0.945 | **+4.9** |
| d3 | 0.792 | 0.900 | **+10.8** |
| d4 (deep) | 0.753 | 0.880 | **+12.6** |

*Qwen3-1.7B-Base (pure transformer). σ = mean P(correct value) over n=27 cells per condition (3 variable names × 9 values). Suffix: `# No changes.\n` appended once.*

### Why this matters

**For AI inference:** One appended fixed comment line produced a meaningful response gain at deep nesting in this model and prompt family. That makes suffix-conditioned readout a concrete inference control to test across transformer systems; transfer, latency, and end-to-end cost remain open measurements.

**For evaluation:** The result shows that a nested-reasoning score can depend materially on the text immediately before readout. It does not establish that the answer was already encoded or that extra computation alone caused the gain; it makes those mechanisms experimentally separable.

**For latent-space theory:** The measured response is depth-dependent and suffix-sensitive. The historical unresolved question is how to separate lexical cueing, position, added computation, and attention-state change before testing a transition law across templates, tasks, and architectures. This panel is deferred; current work follows the [strategy boundary](theory/CUMULATIVE_CAPABILITY_ACQUISITION.md#next-work-boundary).

### Key findings

1. **The tested content contrast exceeds the variable-mention contrast.** In a 2×2 crossover, the assertion-versus-misleading contrast was 6.3× the variable-mention effect. This rules out variable mention alone as the explanation on that panel; it does not isolate meaning from every surface feature. Responses also differed between paraphrases, as described below.

2. **No stable operator algebra on the response simplex.** Lumpability of the (correct-digit, shadow-digit, residual) projection was high ($R^2$ = 0.79–0.98 across 7 role types), but the fitted stochastic-matrix operator did not survive composition: behavioral equivalence between surfaces was not preserved under a second suffix (amplification 2.6–13×), and a scalar logit-bias model fit the single-suffix data as well. The simplex operators are a diagnostic, not a native coordinate system.

3. **Single-count maximum with depth scaling.** Among tested suffix counts {0, 1, 2, 4}, suffix count 1 yields the highest σ at all depths d2–d4. The absolute gain rises from 1.2 pp at d1 to 12.6 pp at d4.

4. **Responses are surface-specific, not role-specific.** Different surface texts within the same semantic class produce detectably different response shifts (within-class coefficient of variation 0.33–0.51). The model distinguishes paraphrases that humans consider equivalent; no role-level operator was established.

5. **Order effects are positional, not compositional.** Applying suffix A then suffix M produces a measurably different output distribution than M then A (median TV = 0.068). Controlled experiments with three independent token-matched filler pairs confirm the order effect is real and consistent (cross-pair correlation 0.69–0.92), but a scalar gain fit absorbs it: the effect direction is positional and the magnitude is context-dependent. A later reading of the same filler data showed that equal-length, position-matched blocks do not produce equal effects either (differences above 0.002 in at least 23 of 24 roots for every filler), so "position" here means the relative offsets to earlier content together with the content of the appended block, not token count alone.

6. **Presentation differences survive a neutral continuation and are exposed by a reassignment announcement.** On a 24-cell panel with three same-meaning surface pairs, the neutral comment `# No changes.` kept all 32 initially close pairs within 0.01 total variation on the 11-bin readout, while the comment `# Reassigning {var} now.` separated 29 of them. This is a reduced-readout, unmatched-position observation about which continuations reveal which distinctions; it establishes nothing about erasure or about the full next-token law.

## Supporting foundation: which distinctions can a model safely forget?

The supporting theory studies interchangeability of histories relative to a family of future questions: two histories are interchangeable for a question family if every question in the family answers the same, and the organizing quantity is how much a later action can re-separate histories that were interchangeable before it. Results so far are mathematical and conditional: exact selective overwrite has a lens structure (preserved context times store); transition-closed realization sets give history-length-independent error bounds; a finite behavioral state budget of N places turns local update errors of size ε into a lifetime error of at most $(N-1)\varepsilon$, sharp; contraction is a sufficient but not necessary certificate. A trained 17K-parameter overwrite cell realized perfect fact replacement on its training panel without being a contraction on its state cube, which closed the coordinate-certificate route. No real-model artifact has been established. That prior line leaves open whether genuinely close real-model histories exist on a matched-position, full-law interface and which matched continuations separate them; it is not the current run queue.

## Nine Breakpoints: Design Constraints for Native Mathematics

The first nine breakpoint themes summarize constraints from the Phase 1 experiments. They are clues about tested interfaces and constructions, not universal failures of vector mathematics. The registry also contains later themes; the underlying audited records control their scope.

| # | Breakpoint | What it means |
|---|---|---|
| 1 | **Presence =/= causation** | A concept can be strongly decodable yet have zero causal effect. Linear probes find ghosts. |
| 2 | **Single-site =/= distributed** | Specific interventions show whole-state dependence for factual recall. |
| 3 | **Vector distance =/= semantic distance** | Points close in cosine can be behaviorally different. |
| 4 | **Fixed dimensions =/= fixed structure** | Effective dimensionality may be context- and task-dependent. |
| 5 | **Vector composition =/= computational composition** | The model composes through its forward pass, not through vector arithmetic. |
| 6 | **Observation =/= state** | The act of choosing what to probe constrains what you can find. |
| 7 | **Snapshot =/= computation** | A representation at layer *l* can't be understood without the trajectory through all layers. |
| 8 | **R^n tools find R^n structure** | PCA finds linear structure because PCA *is* linear structure. The measurement imposes itself on the answer. |
| 9 | **Metric blindness to composition** | Four fact-worlds with cosine ~1.000 produce dramatically different behavioral outcomes under intervention. |

Full details: [`theory/BREAKPOINT_REGISTRY.md`](theory/BREAKPOINT_REGISTRY.md)

## Method: Scope-Variable Binding (SVB)

Python lexical scoping as a probe for latent-space depth structure. Nested `def` blocks create scope depth 1–4, each shadowing a variable. The model processes the code and must report the value at the outermost scope. The response is decomposed into an 11-bin probability distribution ({digit 0–9, OTHER}).

**Observable:** σ (scope binding fidelity) = P(model outputs the correct outer value).

## Repository structure

```
theory/ Axioms, breakpoint registry, continuation-refinement calculus (CR-1 to CR-16)
closed/ Theory of closed lines (archived, headers mark status)
experiments/ Core experiment runners and bounded strategy probes
config/ Experiment configurations (JSON)
results/ Result files (small; every result.json kept; bulk dumps listed in MANIFEST.md)
ledger.jsonl Machine-readable experiment log
EXPERIMENTS.md Human-readable experiment summaries, newest first
docs/ Archived state, notebook, and handoffs
legacy/ Prior program (archived)
STATE.md Canonical current state of all claims
NOTEBOOK.md Reverse-chronological running log (recent); older entries in docs/
```

## Methodology

- **Behavioral consequences are claim-bearing; representational measurements are diagnostic scaffolding.** We study what models *do*, not what their hidden states "look like." This avoids the R^n projection trap (breakpoint #8).
- **Instrument-first.** Before interpreting results, validate the instrument: baseline retrieval, self-patch controls, sham-patch controls, execution-mode checks.
- **Reproducible.** CPU-only experiments, deterministic seeds, full configs logged. Claim-bearing empirical runs in the ledger include the command, config, and metrics; derived-theory rows carry their theory pointers.

# STATE

## SESSION STATUS: PAUSED by user (2026-09-23)

Work paused at a natural boundary of the HP-G arc. Nothing running.

Canonical resume point: AGENTS.md pause section. The standing record

below is current and complete through the pause.

## CURRENT DIRECTION: Mathematics of High-Dimensional Spaces

**Status: ACTIVE (user ruling, 2026-09-18).** A mid-file "HD MATH DIRECTION:

CLOSED" verdict was a coding subagent overstepping its review mandate and is

void; the corrected block appears below. Adversarial reviews (headless

`droid exec`, every 2–3 hours during research sessions) are goal-aligned

adversaries: they attack the method and strategy to ensure the work is the best path to the goal, diagnose what is going wrong, and prevent overclaiming — assuming the axiom is true; they never close a direction or void the axiom. On a failed cycle the required question is "this is not working — what would work for exploring this problem statement?"

How does math change at high dimensions? This is the core research question.

---

## ACTIVE CYCLE HP: spectral law of Zipf-trained superposition codes (2026-09-18)

Spec (pre-registered, frozen): theory/HD_POWER_LAW_ALLOCATION.md (v2 after a Droid design gate returned NO-GO on v1 with five fixes; both verdict and redesign are in the ledger). Established so far:

**Theorem (licensed).** The quadratic superposition autoencoder $L = \Sigma_i p_i \|W^T W e_i - e_i\|^2$ with $d < n$ has global optimum = orthonormal exact storage of the top-d usage tokens, minimum loss $\Sigma_{i>d} p_i$ (tail mass), optimal frame operator $I_d$ (perfectly flat spectrum). Proof: $L = \mathrm{tr}((G-I)P(G-I))$ with G PSD rank $\leq d$; on ker G the factor acts as $-I$. Empirically matched by L-BFGS multi-init optima to 6 decimals at 6/6 configs. Mean-field (random-mixing) stationarity is REFUTED at the optimum (profile $R^2$ 0.00–0.08); the optimum anti-mixes.

**Licensed consequence.** Power-law eigenspectra cannot be global optima of this diagonal quadratic objective; dynamics or assumptions absent from that objective (correlations, constraints, regularization, retrieval margins) are required.

**XE result (3 seeds, licensed 2026-09-19):** unigram tied-softmax training converges toward the H1 rank-2 collapse — top-2 eigenvalue share $\geq 0.984$ at every checkpoint from t=3k, norm uniformization (spread 1.9 → 1.4), curved fits beat power law at 12/12 checkpoint-seeds ($r^2$_pl only 0.54–0.71), and measured $\alpha$ □ the norms-only control (N1-t $\approx 0.22$) — the fitted slopes are directional structure (collapse coherence), not norm allocation. Entry-101's "Zipf + cross-entropy → power-law eigenspectra" is an estimator artifact on a two-spike-plus-floor spectrum. Scoped statement: in the specified diagonal QSAE optimum and the three tested unigram tied-softmax runs, usage alone did not yield genuine power-law spectra — this does not cover structured tasks or other objectives; both toy tasks are underconstrained (quadratic permits tail-dropping; unigram retrieval has no input-dependent requirement), a generalization boundary stated per review-4. HP-D (theory/HPD_ALLOCATION_THEOREM.md) targets the structured-retrieval phase-transition theorem T4 (critical d*(n, rho, s)); its earlier T2-LOG conjecture was withdrawn for a sign error (review-3) and replaced by the unproved T2-FLAT restatement. HP-B is CLOSED (2026-09-20): XE complete (rank-2 collapse, 3/3 seeds), QSAE 12/12 runs converged with flat endpoints (P-E confirmed on every run); the heavy confirmatory arms were foregone with review-backed provenance (reviews 3-4 demoted them; ~7h/run economics).

**HP-E results (2026-09-19, derived + numerically validated):**
1. Quadratic aggregate law: E[A_2] = k(k-1)||M||_F^2/d^2 proved and validated (P4 crossing at k = sqrt(d) confirmed; concentration confirmed). Scope: quadratic/projection readouts; the degree>=3 extension was REFUTED in its naive form (per-term law is ||T||^2/d^t, and no natural Theta(1) diagonal channel exists at degree>=3) — open with explicit obstruction.
2. E-struct (expectation level, validated; RESCOPED per review-6): for unit-energy features with covariance Sigma, per-pair interference = tr(Sigma^2)/(tr Sigma)^2 exactly; expected aggregate interference becomes order one at k = Theta(sqrt(PR(Sigma))) in the specified expectation-normalized quadratic model. A matching high-probability frontier is proved ONLY in the isotropic case; anisotropic concentration at the crossing is open. Power-law corollary restricted to 1/2 < alpha < 1: crossing at Theta(d^{1-alpha}); at alpha = 1 the scale is Theta(log d); alpha > 1 Theta(1).
Validated: per-pair exact to 0.4-2.4% at alpha <= 0.5; crossings bracketed in 8/8 cells (two registered formal fails carry diagnosed benign causes, logged). Pending rigor: concentration formalization and the matching lower bound with quantifier order. Scope (review-10): this is an exact spectrum-to-expected-interference-onset relation for the specified quadratic model; no operational capacity theorem is established.

**HP-E covariance-sufficiency result (2026-09-19, review-6 lead unit, pre-registered):** at identical covariance, Gaussian-direction and coordinate-sparse feature ensembles share the same expected aggregate interference (to a few %) but the sparse ensemble's concentration collapses (cv 21x, spread 14x at the crossing regime). The participation ratio is an EXPECTATION-LEVEL invariant only; the high-probability frontier requires a fourth-moment/localization functional of the direction distribution — the Next invariant target (candidate: coordinate-kurtosis law for cv(A_2)).

**HP-E localization law (2026-09-19, closed form):** the sharpness of the frontier is controlled by two computable functionals — $cv^2(A_2) \approx 2(\Psi_1-1)/k^2 + 2(\Psi_2-1)/k$ with $\Psi_1 = d^2 \cdot tr\Sigma^4/(tr\Sigma^2)^2$ and $\Psi_2 = d \cdot tr\Sigma^4/(tr\Sigma^2)^2$ for coordinate-sparse directions (exact at α=0 in both terms, both matching measurement; 1.7× quantified residual at the worst inhomogeneous cell; no free constants). Gaussian directions collapse both terms to the 2/k law.
Net program statement: the spectrum (participation ratio) sets the mean interference frontier; for the TESTED coordinate-sparse ensemble, the two functionals of 3l predict frontier sharpness exactly in the homogeneous case and within a 1.7x residual elsewhere; a general governing law is unproved. Covariance alone does not suffice (settled by the two-ensemble test).

**HP-D Orlicz-compression arc (2026-09-19/20, verified chain):** for softmax rank-d compression, KL(q||softmax(z)) = log E_q[e^delta] - E_q[delta] — the cumulant generating function of the logit residual (EXACT identity).
Consequences measured at reproducible stationary solutions (global optimality open): (1) the Fisher law is the

kappa_2 regime and holds where deviations are small (validated at s=0.5
far-below-knee, points within 1.2x); (2) at the tested finite configuration, the best reproducible stationary
solutions found accept ~7x the Fisher-optimal residual variance and exploit
higher-cumulant structure (12 seeds within 0.0005; gap 6.2x/4.7x); whether
these are global optima is open; (3) the variance-KL envelope is
DEGENERATE (inf KL = 0 at any fixed variance via rare huge negative jumps)
— polynomial moments do not govern KL compression; the one-sided
exponential moment does (Orlicz scale); (4) the best reproducible stationary solution satisfies the rank-d
first-order condition to numerical tolerance (gradient field entirely in
the complement block, off-space energy 1.0000); global optimality remains
open;
(5) the attempted SVD-based dual is unbounded without a norm constraint and
the tested regularized dual is vacuous; no useful global dual certificate is
currently known (simplex-native or regularized routes untested beyond these). T4 completion target stands as the tilted-SVD/two-fixed-point
program with verified first-order core.

**HP-E limit-law arc (2026-09-20, exact + validated):** for localized
directions the aggregate interference A_2 is a weighted birthday sum; its
EXACT fixed-k multinomial covariance (derived; validated 12/12 zero-parameter,
ratios 0.76–1.09) supersedes the refuted Poissonized model — the negative
cross-covariance $-(k)_2(4k-6)p^4$ is load-bearing. The exact variance formula gives relative concentration when its cv
vanishes (in the dense regime governed by lambda^2 PR_W); asymptotic
normality additionally requires variance growth and a max-cell/Lindeberg
condition (4h, assembled). Poissonization itself was refuted 2/12 by a zero-parameter
pre-registered test — the cycle (prediction → refutation → exact derivation
→ validation) is the arc's method signature.

---

The scope is broad and fundamental: the native mathematics of spaces where
d >> 1. This includes but is not limited to neural network representations.
Traditional ML, deep learning, pure mathematics — any domain where
high-dimensional structure matters. The dimension range is open (d=100 to
arbitrarily large). LLM latent spaces (d=768-4096+) are one motivating
example, but the math applies to any high-dimensional system: kernel methods,
embedding spaces, random feature maps, high-dimensional statistics, and the
pure geometry/algebra/analysis of R^d when d >> 1.

**Axiom:** Math behaves differently in high dimensions. The phenomena that
emerge — concentration of measure, almost-orthogonal packing, interference,
volume collapse, distance uniformity — are not curiosities but the native
physics of these spaces. Understanding them is the goal.

**Prior work in this repo:** 86 experiments characterizing perturbation
sensitivity in small language models (one source of high-dimensional evidence),
omega modulus measurements, structured negatives about behavioral instruments.
This data is available for reanalysis within the broader frame.

---

## HISTORICAL: Perturbation Sensitivity Analysis (86 entries, ongoing data source)

86 NOTEBOOK entries analyzing how code perturbations affect small language model behavior. Position >> operator >> sign >> identity >> meaning hierarchy established across 3+ architecture families. C-group two-tier split (comment vs code prefixes). Construct-validity question open (Droid review: is hierarchy probe-independent?).

---

## HISTORICAL (within HD-MATH): Theory-First Cycles — Closed (2026-09-18)

Three theory-first cycles attempted to connect HD math to behavioral data, all killed. These are structured negatives about using behavioral instruments to study dimension — not negatives about HD math itself.

**Open questions (initial):**

1. What algebraic structure, if any, do almost-orthogonal packings in d=512-4096 have?
2. Can interference between superposed features be predicted from geometry alone?
3. Does concentration of measure explain granularity-dependent transfer?
4. What are the native operations of these spaces — not R^n operations applied to them?
5. What does calculus look like when d >> 1 and the manifold hypothesis may not hold?

**Known landscape (from literature review, 2026-09-18):**

- Almost-orthogonal packing: ~exp(d) directions, no algebraic structure, d=512-4096 poorly characterized (Luisto 2025 survey, arXiv:2510.23609)
- Computation in superposition: n neurons compute O(n²/log n) features, exponential gap over representation (Hänni et al., arXiv:2408.05451, 2409.15318)
- Spectral superposition: frame operator classifies toy-model geometry, not real networks (arXiv:2602.02224)
- Adversarial interference: geometry predicts vulnerability, transfers across models (arXiv:2510.11709). No composition rules.
- Platonic Representation Hypothesis: coarse convergence known (Huh et al., ICML 2024). Fine divergence known ("Convergence Without Understanding", arXiv:2605.23315).
- Formal superposition theory (arXiv:2608.27540, Aug 2026): frame theory + compressed sensing. Recovery for nearly tight, low-coherence dictionaries up to O(d/log n) sparsity. ETF recovery thresholds computed exactly. Active debate on computation in superposition vs compressed computation (Jun-Jul 2026).

**NEW EMPIRICAL FINDINGS (2026-09-18, entries 88-92):**

Frame-theoretic analysis of 3 trained models (SmolLM2-135M d=576, Qwen3-0.6B d=1024, Phi-1.5 d=2048):

1. **Real models are 100x-10,000x from tight frame ideal.** Embedding condition numbers: 640 (Phi) to 11,971 (SmolLM2). MLP conditions: 180-25,888. The formal superposition theory's assumptions (nearly tight, low coherence) are massively violated.

2. **Coherence is 15-30x the Welch bound.** Embeddings: 0.75-1.00 vs Welch 0.02-0.04. Features are far more aligned than optimal packing predicts.

3. **Eigenspectra follow power laws**, not Marchenko-Pastur (random) or uniform (tight frame). Exponents: -0.35 to -0.90 (full), steepening through depth. Training creates regularity neither random matrix theory nor toy superposition

theory predicts.

4. **Embedding condition decreases with d** (11,971 → 1,175 → 640 as d goes 576 → 1024 → 2048). Higher-d models have more uniform embeddings.

5. **Gate/up asymmetry is universal.** Gate_proj has higher condition, lower effective rank, higher coherence than up_proj. Sharper feature selection vs broader value computation.

6. **Amplification gradient, not tail vulnerability (entries 92, 118).** Entry 92 found natural perturbations with more tail eigenspace energy cause more damage (rho = -1.00 at L29). OVERTURNED by entry 118: controlled fixed-magnitude perturbations into individual eigenspaces show TOP eigenspaces are 3-14x MORE sensitive (beta = +0.25 to +0.41). Entry 92's correlation was confounded — the model's multi-layer processing absorbs top-eigenspace perturbations, leaving tail residuals. Controlled injection establishes greater LOCAL sensitivity in top eigenspaces (amplification gradient); downstream compensation through subsequent layers is one untested explanation for the natural-perturbation reversal, not an established mechanism.

7. **Information-theoretic eigenspace priority (entry 94; wording corrected 2026-09-19).** In the measured embedding, selected rare morphological tokens (strugg-, authent-) had greater top-eigenspace energy than selected common tokens (observation on selected tokens only). The governing variable and any optimality are unestablished.

8. **Power-law spectra require directional structure, not just norm scaling (entry 95).** Monte Carlo test: random embedding directions with information-weighted norms produce FLAT spectra (exponent ~-0.1, condition ~1.5) indistinguishable from uniform random embeddings. The power law therefore comes from training organizing tokens into correlated directions. Directional organization alpha = (obs - random) / (greedy - random): SmolLM2 alpha=0.50, Qwen3 alpha=0.32. Alpha decreases with d — higher-d models need less directional organization. The Zipf sensitivity analysis suggests effective training Zipf exponent ~0.5 (not 1.0).

9. **First-principles: Zipf + cross-entropy → power law (entry 101).** A single-layer embedding trained with SGD on Zipfian tokens produces power-law eigenspectra. Uniform tokens → flat spectrum. The power law is a consequence of training on Zipfian data, not an architectural feature. Exponent is controlled by (Zipf s, n/d ratio): higher overcompleteness → flatter. Phi-1.5 (n/d=25) steeper than Qwen3 (n/d=148) explained. Alpha(d) monotone prediction FALSIFIED; alpha depends on n/d not d alone.

10. **Hierarchical eigenspace clustering (entry 99).** Tokens are concentrated into few eigenspaces: SmolLM2 median erank = 32/576 (5.6% of d), Qwen3 median erank = 326/1024 (31.8%). Concentration ratio inversely tracks power-law steepness. Most concentrated tokens (erank ~3) are rare vocabulary entries aligned with eigenvector 0 at 77-83%.

**CORRECTED (2026-09-19, adversarial review; supersedes "RESOLVED"):** The theory-practice gap between formal superposition theory (tight frames) and real models (power-law-like fitted slopes) is NOT resolved. Finite-time Zipf-trained models produced power-law-like fitted slopes, but the estimator can manufacture such slopes (HP-A A2), and unigram-softmax equilibrium evidence favors non-power-law structure (rank-2 collapse, HP-B XE interim). The structured-data explanation remains open; no mechanism is licensed. Retained context: fitted slopes co-vary with Zipf s and n/d (entry 101); directional organization exists relative to random baselines (entry 95); top-eigenspace allocation tracks token information (entry 94).

**CLOSED PROGRAM: Frame Composition and Mixed Moments (2026-09-18)**

Strategic direction from Droid review (entry 96): develop a predictive calculus for composition and interference in structured HD systems.

**RESULTS (entries 97-98), narrowed per Droid review (entry 102):**

1. Gate and up input-side Gram operators exhibit positive centered Frobenius alignment at all layers (entry 98). D1_norm: SmolLM2-135M mean 0.22, Qwen3-0.6B mean 0.22. Sharing increases coarsely through depth zones. This is a real descriptive finding but not yet predictive or surprising.

2. Synthetic test (entry 97): D1 separates shared-eigenvector from random frames. Valid but elementary — that relative eigenbasis affects matrix sums is established linear algebra. The "pairwise insufficiency" framing overclaims; it shows only that Gram inner product detects eigenvector alignment, which is expected.

3. D1_norm ≈ 0.21 across SmolLM2 scale ladder (entry 100). Three checkpoints, but width, depth, and training are confounded. Not yet evidence of a universal budget.

**WITHDRAWN (per Droid review, entry 102):**

- Formal theorem (theory/mixed_moment_critical_exponent.md): multiple proof errors (log divergence at α=1/2, O(1) contribution below α=1/2, H(s,δ) divergence for s>1, measured exponents 1.1-1.8 outside α<1 derivation). Needs correct rederivation.
- "Effective sharing fraction" (2-15%): divides by unmatched benchmark.
- "Pairwise geometry is provably insufficient": overclaimed framing.
- D_k sufficiency for SwiGLU composition: KILLED by row-permutation argument. Permuting up_proj rows preserves all D_k, all spectra, but changes which gate/up neurons are multiplied → network function changes. D_k discards the row-pairing structure essential for SwiGLU.
- "Universal coupling budget" at 0.21: premature from 3 confounded checkpoints.

**CRITICAL INSIGHT (Droid):** The row-permutation argument shows that any invariant based solely on W^T W (Gram operators) is fundamentally blind to row pairing. SwiGLU computes σ(Wx) ⊙ (Vx), so the i-th row of W gates the i-th row of V. A useful composition invariant must be row-aware.

**Row-permutation challenge DONE (entry 103):** Random permutation of up_proj rows preserves all D_k (diff < 5e-08) but destroys MLP output (139% relative

error, range 1.04-1.64 across layers). Function-preserving control (same permutation to gate+up, inverse to down cols) has zero error (2.5e-07). Separation ratio: 5.5 million to 1. D_k is conclusively insufficient.

**Row-wise cosines are zero (entry 104):** The simplest row-aware statistic — cos(gate_i, up_i) — is indistinguishable from random (mean -0.0009, frac positive 0.499). In d=576, all pairwise cosines concentrate at zero. The row pairing is essential but carries no per-pair directional signature.

**The pairing paradox:** Gram operators show population alignment (D1_norm=0.22). Individual row pairs show no alignment (cos ≈ 0). Yet the specific combinatorial pairing determines the function (139% error from mismatch). The compositional information exists at no single natural level of analysis.

**Row-permutation series (entries 103-106, corrected by entry 107)**

Clean result: D_k sufficiency is killed (entry 103). Any invariant factoring only through G^T G and U^T U cannot characterize a SwiGLU block. The 139% error ≈ sqrt(2) (random decorrelation), mostly from DU disruption (additive error 0.88). Entry 105 has a mathematical error (m×m cross-matrix SVD is exactly permutation-invariant by construction). Entries 104-106 overclaimed; the correct framing is hidden-unit gauge symmetry, not "tensor phenomenon."

**CLOSED: Tensor composition line (entries 97-109)**

Started: D_k mixed moments detect shared eigenvector structure (entries 97-98).
Killed: D_k sufficiency killed by row-permutation argument (entry 102-103).
Investigated: Row cosines, cross-matrix SVD, bilinear sensitivity (entries 104-106).
Overclaim corrected: Gauge symmetry, not tensor phenomenon (entry 107).
Final test: Weight-only tensor predictor ||ΔT||_F ≈ DU predictor ||DΔU||_F (entry 109). Gate structure adds nothing for damage prediction. Line closed.

**What survives from this program:**
1. D_k sufficiency is cleanly killed (entry 103) — valid structured negative
2. Power-law-LIKE FITTED SLOPES from Zipfian training (entry 101) — status downgraded 2026-09-19: estimator-manufacture and transient/equlibrium structure both implicated (HP-A A2, HP-B XE interim); origin open
3. Information-theoretic eigenspace priority (entry 94) — positive finding
4. Gate/up Gram alignment exists descriptively (D1_norm ≈ 0.22) — but not compositionally meaningful
5. Permutation damage is predicted by ||DΔU|| — the down-up product, not gate-up coupling
6. Spectral-composition bridge REJECTED (entry 110) — spectral structure and compositional pairing are INDEPENDENT; training does not jointly organize them
7. Additive anti-pairing (entry 110) — additive MLPs develop z=-7.79 spectral anti-pairing (gate and up project with opposite signs onto top eigenvectors); gating DISRUPTS this, freeing pairing structure from spectral constraints. This explains WHY gated MLPs are pairing-sensitive (entry 106).
8. Output spectral pairing dipole (entry 111) — CONFIRMED CROSS-ARCHITECTURE. Near-output layers develop a sign-structured pairing pattern. SmolLM2 L28: top5_z=+2.48, 137/576 positive-significant. Qwen3 L27: top5_z=+1.80, 240/1024 positive-significant. Both ~25-28% sig fraction. Preceding layers show anti-pairing (Qwen3 L26: z=-2.35, 122 negative). "Spectral dipole"

at the output. Middle layers show z≈0 (aggregate p>0.29 in both models).

**ACTIVE DIRECTION: General Mathematics of High-Dimensional Spaces (2026-09-18)**

Pivot from model-specific experiments to GENERAL HD math. Scope: pure mathematics, statistical physics, information theory, random matrix theory, kernel methods — any domain where d >> 1. Models are ONE source of evidence, not the primary object. Analytical derivations and proofs take priority over running code on specific models.

**Analytical results derived (2026-09-18):**

1. **Interference hierarchy (rescoped 2026-09-19 per adversarial review):** For isotropic random unit features and a suitably normalized fixed quadratic form, an individual off-diagonal bilinear term has RMS O(d^{-1/2}) (shown). The general t-body and — crucially — the AGGREGATE k(d)-body laws (combinatorial multiplicity vs per-term suppression) remain conjectural and are the HP-E theorem target: candidate threshold k* = Theta(d^{(p-1)/p}).

2. **Packing vs recoverable capacity (corrected 2026-09-19 per adversarial review):** Packing permits exponentially many candidate directions. Recoverable simultaneous capacity depends on the decoder, task and error model; no universal linear or bilinear capacity law is established (orthonormal features permit a bilinear layer to compute k ≤ d diagonal quantities exactly). Any capacity theorem must specify ensemble, task, decoder, noise, error probability and k(d) before a threshold claim.

3. **Scalar allocation benchmark (corrected 2026-09-19):** The scalar resource-allocation problem (minimize $\sigma^2 \Sigma\, p_i/\lambda_i$ s.t. $\Sigma\lambda_i = P$) has optimizer $\lambda_i \propto \sqrt{p_i}$. Its interpretation as an eigenspectrum law or a $d \to \infty$ limit is unproved and, per the HP theorem, cannot describe quadratic-loss equilibria; retained only as a labeled diagnostic.

4. **Gauge symmetry of eigenspectra:** Embedding eigenspectra are GL(d) gauge-dependent. The training-chosen gauge has physical meaning through amplification (top = amplified more, per entry 118), but the spectrum itself is not a fundamental representation property. Entry 92's "tail vulnerability" was overturned — see finding 6 above.

5. **Capacity bounds (corrected 2026-09-19 per adversarial review):** Particular random-feature and error models may yield √d-type thresholds; no general coherent-case or depth-capacity law is established. Any threshold claim must fix ensemble, task, decoder, noise and error criterion first.

**Connections to established mathematics (to formalize):**

- Hoeffding decomposition (statistics): ANOVA-like variance decomposition on product spaces
- Wiener-Itô chaos expansion (probability): polynomial chaos in Gaussian Hilbert space
- Cluster expansion (statistical physics): systematic corrections to mean field
- 1/N expansion (gauge theory): planar diagram dominance in large-N limit
- All share the same structure: ordered correction hierarchy suppressed by a large parameter

**Open mathematical threads:**

1. Rigorous proof of interference hierarchy for general degree-p polynomials
2. Spectral calculus: closed-form evolution equations for eigenvalue distributions under gradient descent / stochastic dynamics in HD

3. Phase transitions in superposition capacity (sharp thresholds in k vs d)
4. HD calculus: gradient concentration, Hessian spectra, optimization landscape
5. Connection between interference hierarchy and neural network depth requirements
6. What makes structured (trained) features different from random features in the interference hierarchy — how does training break the incoherence assumption?

**Prior model-specific findings (available for reanalysis under new framework):**

**Open targets from prior program (updated by entry 118):**
1. Power-law spectra as computational structure (entries 92-95, 101, 118). Entry 118 overturns entry 92's tail vulnerability: controlled perturbations show TOP eigenspaces are more sensitive (beta=+0.3) — an amplification gradient. Whether later layers compensate (the natural-perturbation reversal) is untested; fitted power-law exponents themselves now carry estimator-bias caveats (HP-A A2) and their origin is open (HP cycle).
2. The additive anti-pairing discovery (entry 110) may have implications for understanding why gated MLPs outperform additive MLPs — the gating mechanism decouples pairing from spectral structure, enabling richer computation.
3. Depth-dependent pairing organization (entry 111) — does the penultimate-layer positive pairing generalize across model families?
4. Spectral steepening: DESCRIPTIVE, NOT PREDICTIVE (entries 112-115). Up_proj steepening confirmed across 3 models (rho < -0.65). Scale-invariant rate (~-0.15 normalized). Complementary specialization survives LN confound (post-LN rho=+0.45). BUT spectral exponent does NOT predict layer sensitivity (entry 115 NEGATIVE). Sensitivity is U-shaped (position-driven, not spectrum-driven). The depth gradient characterizes training dynamics, not functional importance.

**Finding 10 (entry 113): Complementary specialization — weights and representations anti-correlate.**
Hidden state spectra FLATTEN with depth (rho=+0.871, p<0.001) while weight spectra STEEPEN (rho=-0.891) — oppositely moving fitted slopes in one model and sampled corpus, after normalization. Causal relationship and functional significance (accumulation, compensation, efficiency) are unestablished.

**Finding 9 (entry 112): Spectral depth gradient — CONFIRMED CROSS-ARCHITECTURE.**
MLP up_proj power-law exponent steepens monotonically with depth: SmolLM2 rho=-0.891, Qwen3 rho=-0.649 (both p<0.001). Gate follows. Attention QK/OV ranks show no depth trend. Creates a generalization-to-specialization gradient: early layers use many spectral directions (flat spectra), late layers concentrate on few (steep spectra). The pairing dipole (entry 111) sits at the extreme end of this gradient.

**Data from prior programs (available for reanalysis):**

- 7-model balanced kill: 69 cells × 24 perturbations, full-logit cosine distances
- 2×2 D-reliability diagnostic: within-op +0.632 >> cross-op +0.366 (Qwen3-0.6B)
- Omega modulus: ~28,000 readouts, 5 architectures, continuation-dependent sensitivity
- Scale ladder: SmolLM2 135M/360M/1.7B, Qwen3 0.6B/1.7B, base and instruct variants

**Empirical findings (2026-09-18, geometry probes, SmolLM2-1.7B d=2048):**

Finding 1: For diverse inputs (arith+NL+code), representation geometry shows MONOTONIC CONCENTRATION through layers — no hunchback. eff_dim stays 1-3.

Finding 2: The "spread-then-concentrate" hunchback appears only when the extraction-position token is IDENTICAL across inputs (context propagation artifact, not a computational signature). Probe 1 shared "# Output: " suffix → identical last tokens → apparent hunchback. Probes 2-3 with varying last tokens → no hunchback.

Finding 3: Cross-class cosine at mid-layers converges (arith-NL cos≈0.55 at L12-L20), then the FINAL LAYER re-separates domains. Arith-code stay close (0.70), NL splits from both (0.35-0.37). The final-layer cross-class cosine reflects next-token vocabulary overlap.

Finding 4: Within-class final-layer cosine: arithmetic (0.96) > code (0.82) > NL (0.81). Input homogeneity maps directly to representation homogeneity.

**Fable review (2026-09-18):** All geometric patterns (ID hunchback, trajectory convergence, anisotropy) have extensive prior art (5+ papers 2024-2026). The "interference tensor" concept has prior art. Category error identified: input-to-input cosine ≠ feature superposition geometry. Actionable paths: fix methodology, engage published frontier (Representational Capacity 2606.02765, Geometric Wall 2605.09887), or build predictive models.

**RMT / Composition analysis (2026-09-18, KILLED):**

MP-deviation analysis: eigenvalue spikes above Tracy-Widom exist in all 7 models (1-3 spikes each) but add NO predictive power over standard PCA for behavioral transfer prediction. Kill criterion #2 triggered.

Interference composition: product rule r(i,k) ~ r(i,j)*r(j,k) shows positive residual (+0.14 mean, all 7 models), but this is entirely explained by 3 shared vulnerability factors (PCA). After factoring, residual flips negative.

**Fundamental constraint (2026-09-18):** The behavioral transfer data (69×24) is intrinsically rank-3. Three architecture-family-specific factors capture 79-97% of variance. No high-d math can extract structure that doesn't exist in the data.
The dataset is exhausted for high-d analysis. High-d investigation requires genuinely high-d data (hidden states d=768-2048).

**Theory-first attempts (post Fable R3, 2026-09-18):**

Three theory-first cycles attempted, all killed:
1. Concentration-of-measure bound on behavioral rank → routing prediction killed (base vs instruct have identical attention routing despite 2× behavioral PR)
2. Weight spectral bridge → no correlation (all p>0.25; base/instruct have identical weight spectra but 98% different behavioral PR)
3. Jacobian derivation → Fable R4 KILL. Value/routing decomposition is backwards, perturbations not in Jacobian domain, and the one sharp prediction (d_add_zero should be A-like) is falsified in 6/7 models. Theory = QK/OV split (2020) + adversarial examples Jacobian (2015). See scratchpad/fable_jacobian_r4.md.

**d_add_zero dissociation (from R4 review, zero-cost):** A perturbation that appends "+ 0" (touching zero original expression positions) does NOT behave like an inert suffix. rho(add_zero, A) ranges 0.06-0.86 vs AA baseline 0.64-0.94. Position of the edit does not determine behavior; whether appended tokens enter the computation the readout must perform DOES.

**Fable R3 criterion #1 triggered (closure clause VOID per user ruling 2026-09-18):** 3 cycles, 0 surviving testable predictions. Next attempt must state a numeric/ordinal prediction absent from existing data BEFORE examining data. The "or the HD math direction closes entirely" consequence is void: reviewers flag overclaims and approach problems; they do not close the mission.

**Computational-relevance test REJECTED (Fable design review, 2026-09-18):** Pre-registered "syntactic context determines behavioral sensitivity" with 6 new perturbation types. Fable REJECT: predictions already confirmed by R29 inline-inert data and R31 `//`-disambiguation (both in NOTEBOOK), threshold fitted to calibration data, confirmatory outcome is tautological ("model knows Python"), disconfirmatory outcome has 3 untested alternatives the design cannot separate. Not counted as an HD math attempt (behavioral sensitivity, not HD math, by its own admission).

**HD MATH DIRECTION: ACTIVE (user ruling, 2026-09-18).** The earlier "CLOSED" verdict that stood here was a coding subagent overstepping its review mandate, not a scientific result. Three theory-first cycles failing to produce surviving predictions is evidence about those cycles, not license to retire the mission. The user direction stands: explore the mathematics of high-dimensional spaces, with LLM latent spaces as one later instance (they are too expensive on current hardware and have too many moving parts; the general HD foundation comes first). What the killed cycles DO establish, retained as method guidance for the next attempt: (1) the rank-3 behavioral transfer matrices are exhausted — do not re-mine them; (2) the open route is analytical/proof-first work on genuinely high-dimensional objects (weight matrices, hidden-state geometry, random-matrix and kernel regimes); (3) any empirical claim states a numeric/ordinal prediction absent from existing data BEFORE examining data. On a failed cycle the required question is "this is not working — what would work for exploring this problem statement?", never closure. The behavioral sensitivity program's surviving yield (multiplicative model, 4-level transfer hierarchy, d_add_zero dissociation, R31 disambiguation, omega amplification) remains retained below.

**What survived (total yield of the kill experiment program):**

- Multiplicative sensitivity model d[i,j] ≈ f[i] × m[j], $R^2$=0.82-0.88
- 4-level transfer hierarchy (operator type, difficulty, magnitude, cell×pert)
- Behavioral rank k=1-6 varying by model; instruction tuning quadruples rank
- d_add_zero dissociation: computational relevance, not position, determines sensitivity
- R31 `//` disambiguation: 10x effect from surface-dependent parse (a genuine finding)
- Omega modulus: cross-architecture amplification phenomenon (mechanism unresolved)

---

## HISTORICAL: OMT-0: Omega Modulus Transfer Test — structured positive (2026-09-17)

The omega modulus (modulus of continuity under behavioral distance) is a measurable, cross-architecture phenomenon. ~24,000+ readouts across 55+ experiments, 5 architectures. Mechanism unresolved; prospective predictive value under test.

**Cross-architecture confirmation.** Three architecture families show amplification: Qwen3 (0.6B/1.7B/4B), StableLM-2-1.6B, and Gemma-3-1b. Pythia-1.4B shows zero (insufficient code training). The amplification pattern is model-dependent:

Qwen3 ranks identity highest; StableLM ranks neutral highest; Gemma ranks pass highest. The universal finding: code continuations amplify behavioral distance relative to no-op baselines, across architectures.

**Scaling.** Identity amplification scales monotonically within Qwen3: 0.003 (0.6B) -> 0.014 (1.7B) -> 0.051 (4B).

**Generalization axes confirmed:** cross-variable (83-92%), cross-pair leave-one-out (+27.5pp at tau=0.01), cross-query format (100% at tau=0.02), cross-code-structure (60-80% at tau=0.05), perturbation diversity (14/14 novel types amplify), rank-based cross-pair (Spearman rho=0.52, predictor 71-86%).

**Held-out prediction.** Omega trained on standard continuations predicts novel perturbation types at 83.3% (tau=0.05), +33pp over naive baselines. Statistical significance: Cohen's d=3.49, permutation p=0.0004 for core effect.

**FRONTIER: Observed step (exp #31).** Omega shows a sharp jump at the first identity statement: 0.003 (no identity) -> 0.047 (one identity) within the tested suffix conditions. Non-monotonic with repetitions (rep_2 < rep_1, interference effect). Pure neutral comments × 4 amplify MORE than identity (catalysis, 0.106). Not an established phase transition in the formal sense.

**FRONTIER: NL omega comparable to code under full-vocab TV (exp #32, #37, #39, #45).** The 11-bin projection concealed NL differences (ratio 18,000-64,000x). With full-vocab TV (exp #45), NL omega amplification (5-17x on tested pairs) reaches code-range levels. Passive voice pair: question mark amplifies 16.9x (0.028->0.474), period 10.6x. house/home pair: period 5.6x (0.090->0.502). Code pairs also lose signal in 11-bin when differences aren't in digit tokens (boundary_pair: full/11bin ratio 3-21x). The small, unmatched panels do not establish a general domain ordering; only one of four NL pairs meets full-vocab baseline tau=0.05. The 11-bin readout is a code-specific optimization.

**FRONTIER: Base/instruct profile differences (exp #33, CORRECTED by exp #39).** Base vs instruct omega profiles differ substantially on Qwen3-1.7B. On matched cells (eligible in both models), heavy RISES from #3 (base, 0.034) to #1 (instruct, 0.158) — 4.6× stronger. The original exp #33 headline ("instruct suppresses heavy") was an artifact of comparing different eligible cell sets. Cross-architecture (StableLM): reshaping replicates but in architecture-dependent direction. NOTE: base/instruct differences do not causally isolate RLHF from other training differences (data mix, SFT, etc.).

**FRONTIER: Layer-wise profile (exp #35).** On 1.7B: omega is monotonically increasing through model depth. Layers 0-16: omega≈0 (10^-5 to 10^-7). Layer 20: first nonzero (0.0003). Layer 24: 0.010 (100× jump). Final: 0.049. Heavy is the earliest amplifier (detectable at L12). No compression bottleneck. NOTE: layer readout profiles do not causally localize a circuit or establish variable tracking; they show where omega becomes measurable, not mechanism.

**FRONTIER: Quantization (exp #34).** INT8 dynamic quantization reshapes the omega profile as dramatically as base/instruct differences. Identity drops from #1 (0.047) to #5 (0.003). Mean TV(fp32, int8) = 0.378. Omega profiles measured at fp32 change

substantially under int8; certification transfer was not established. Omega is precision-dependent.

**FRONTIER: Pair property (exp #44).** Tested 12 pairs to find what predicts identity amplification vs preservation. REFUTES the "strong vs tight" framing: identity amplifies only 2/8 eligible pairs (assert_pair I/N=1.5×, minimal_ok_good I/N=2.5×) while PRESERVING for 6/8 — including "known strong" pairs (strong_assert I/N=0.3×). Heavy is the strongest amplifier across all tested pairs (0.03-0.45). No simple predictor works: not semantic category (value/structure/name change), not baseline TV, not token diff count. The governing pair property remains an open question.

**Known limitations.** Cross-pair threshold prediction fails at tau=0.01-0.02 (omega is pair-dependent). Operational threshold: tau=0.05. Architecture-specific amplification rankings mean omega magnitude is not directly comparable across models. NL and code tau thresholds are on incomparable measurement scales (11-bin vs full-vocab TV).

**FRONTIER: Partial identity tokens (exp #38, BOUNDARY BUG IDENTIFIED by Fable R3).** The "progressive buildup" narrative (x→x=→x=x→x=x\n) and "newline reduces 4×" finding are ARTIFACTS of broken prompt assembly: continuations without trailing \n get glued to the query (x becomes xf(), x= becomes x=f(), x=x becomes x=xf()). Among VALID continuations only: x=None (0.367) > x=y (0.236) > type(x) (0.207) > x=x\n (0.164) > x=1 (0.134) > #x (0.124) > _=x (0.077) > newline (0.070) > pass (0.036) > nothing (0.007). The valid-continuation ranking still shows 23× amplification for identity vs nothing, and any assignment amplifies. But the mechanistic claims about progressive buildup and newline dampening are WITHDRAWN pending boundary fix experiment (Fable Rank 1).

**FRONTIER: Repetition disentanglement (exp #40).** The interference from exp #31 (rep_2 < rep_1) is pair-dependent with OPPOSING directions. Strong pairs: additive (II>I), last-statement-wins (NI>IN), neutrals accumulate (NNN>NN>N). Tight pairs: OPPOSITE — suppressive (II<I), first-statement-wins (IN>NI), ending on identity preserves. I_paraphrase (identity via temp swap) dramatically different from direct I (0.001 vs 0.022) — syntactic form matters, not just semantics.

**FRONTIER: Layer scaling (exp #41).** 0.6B onset at L8 (vs L20 in 1.7B) — EARLIER in smaller model. But weaker final layer (0.024 vs 0.049). The 0.6B distributes omega across many layers; 1.7B concentrates sharply in L20-27. Larger models develop more specialized late-layer variable-tracking circuits. 0.6B loses eligible cells at L16-20 (representations less stable mid-network).

**Mechanistic (CORRECTED by exp #46/#47 boundary fixes + Fable R3 + Codex R1).** The amplification mechanism is UNRESOLVED. "Continuation-dependent sensitivity" is an accurate description: appended context can increase or decrease distinguishability of selected histories under a specified next-token readout. The effect depends on histories, continuation, query, model, and measurement channel. Exp #47 (192 readouts, proper prompt boundaries): on strong_assert_2, bare_var_nl (`x\n`) is strongest (25x), nonvar_expr (`_ = 42\n`) amplifies 10x (same as identity_nl), pass_stmt only 2.7x. Critical: glued_identity (11x) ≈ identity_nl (10x) — the #38 boundary confound does NOT explain away the identity effect. WITHDRAWN claims: "progressive buildup" (boundary bug), "newline dampening" (boundary bug), "variable

context activation" (nonvar amplifies strongly), "computation context activation" (still a hypothesis per Codex R1 — NL punctuation and neutral comments undermine any claim that computation-adjacent syntax is necessary). Variable mention modulates magnitude but is not required. Heavy is the strongest amplifier across all tested pairs (exp #44). Remaining alternative explanations (Codex R1): readout redistribution rather than recovered information; ordinary access to retained history; position/tokenization/query interaction; confidence changes (softmax saturation); selection effects from maximizing over continuations.

**FRONTIER: Authority framing (exp #43).** Adding source-frame comments before continuations dramatically changes omega. On tight pairs (minimal_ok_good): "# According to the documentation:" before neutral SUPPRESSES omega 97% (0.034x). On wide pairs (strong_assert_2): same frame AMPLIFIES neutral 3.5x. The model processes frames differently depending on the baseline distance landscape.

**FRONTIER: Comment taxonomy (exp #44).** Systematic test of 21 comment types across 7 semantic categories. On tight pairs: safety comments ("SAFETY: do not modify") are the STRONGEST amplifier at 7.45x bare identity. Deprecation ("DEPRECATED: will be removed") is the strongest suppressor at 0.15x. Category ranking: safety > uncertainty > explanation > certainty > authority > deprecation. Safety implication: a "do not modify" comment actually INCREASES model sensitivity to following code, opposite of its intent.

**DATA: Baseline predictor (exp #46, analysis only).** Baseline TV correlates with max omega globally (rho=0.738). Within-pair patterns are noisy: strong_assert_2 rho=-0.31 on n=6 (p=0.54, R5 WITHDRAWN as evidence of inversion). The global correlation is dominated by the ineligible strong_assert pair.

**FRONTIER: Diagnostic set (exp #45, METHODOLOGICALLY FLAWED per Fable R3).** The greedy selection score is circular — any 2-element subset trivially gets rho=1. The reported rho=0.606 is NOT a valid coverage measure. Raw observations useful; the compression/efficiency claim is withdrawn.

**FRONTIER: Referent crossover (exp #50, #51; REVISED by R4 + eligibility reanalysis).** On eligible cells (12/18, tau=0.05), the gradient SURVIVES in a cleaner form: baseline(0.009) < tracked(0.028) < none(0.068) < other(0.087). All three pairs individually show tracked < other. The original "gradient reversal" was an artifact of inflated baselines (0.296 from ineligible cells with TV 0.05-0.48). tracked_value (`x = 1`) writes the answer into the prompt. "State confirmation anchor" and mechanism labels are withdrawn. Exp #51 dual-variable: 100% eligible (all baseline TV < 0.048); TSI = -0.008 at noise floor. #50 and #51 are one reproducibility check, not independent evidence.

**FRONTIER: Revival (exp #42, 756 readouts; REVISED by R4 + eligibility reanalysis).** R4 analyzed unfiltered data (including strong_assert, baseline TV=0.88) and found 1/25 chains exceeding control. Eligibility-filtered reanalysis (336/756 rows at baseline≤0.05): 9/30 chains exceed no-contraction control — substantially stronger. del_var consistently amplifies 3.3-3.8x across all probes on eligible cells (expected: NameError context). none_assign+isinstance_check: 0.086 vs 0.042 control (still real). blank_newlines+type_var: 0.094 vs 0.085 (marginal). strong_assert pair entirely

ineligible (0/252 cells, baseline=0.88). Revival is real but narrow: ~30% of chains on eligible cells. LIMITATIONS: 11-bin only; del_var is trivially explained.

**FRONTIER: Consequence prediction (exp #49/#53, 576 readouts (not 864; #48=#49); REVISED by Fable R4 + eligibility reanalysis).**
All-cells: 126 rows, 12 flips, AUC 0.939, r_pb=0.690. Eligible-only (tau=0.05): 84 rows, 7 flips, AUC=0.918, r_pb=0.639 — result SURVIVES eligibility filtering with modest degradation. 12/18 cells eligible (5/6 strong_assert_2, 3/6 boundary, 4/6 minimal). Single-surface top-2 margin gets AUC 0.80-0.86 (R4); TV's 0.94 is real pair-specific information but 80% of signal available from one surface. TV and flip are computed from the same vectors (structural coupling). `heavy` scoring contaminated (scores x+1 against pre-mutation value). Transfer across QUESTIONS is untested — that is the real omega claim (exp #58 in progress). On BASE model (exp #53): weak predictor (test F1=0.129). The strong result is instruct-specific.

**FRONTIER: Cross-model consequence (exp #55, 432 readouts, NEGATIVE).** tau=0.3 does NOT transfer across model sizes. TV-flip correlation is non-monotonic: 0.6B-Base r=0.307, 1.7B r=0.677, 4B-Base r=0.284. Best thresholds are model-specific (0.6B: tau=0.05/F1=0.14; 4B: tau=0.15/F1=0.33). At tau=0.3, both 0.6B and 4B have F1=0.000 (no pairs exceed TV=0.3). The pattern: 0.6B is too weak (2.3% accuracy, near-chance — barely understands scoping); 4B is too robust (91.2% accuracy, 2.8% flip rate — almost never flips). 1.7B sits in the "vulnerable but capable" sweet spot. Consequence prediction via omega requires a model in a specific capability regime for the task, not a universal property.

**CANCELLED: Identity paradox (exp #54; WITHDRAWN by Fable R4).** There is no paradox. Identity has the lowest mean TV of all continuations (0.048) and the highest margin (0.70). Zero flips at TV 0.05 is the expected outcome. The "compression vs redistribution" taxonomy was derived from instruct-model data. Cancel.

**FRONTIER: Autoregressive compounding (exp #56, 64 trajectories × 30 tokens; DOWNGRADED by Fable R5 — pending E1 rerun).** Under greedy decoding on 32 surface pairs (17 eligible), 11-bin cross-surface TV after 30 generated tokens is near 0 for 13 pairs and above 0.94 for 19; 28 of 32 pairs exceed TV 0.9 at some step. The step-30 label is NOT stable across horizons — changing to step 20 or 40 changes labels. Whether the two generated texts converge or merely phase-align was not recorded (token ids not persisted). The rival explanation: coarse-readout phase alignment under greedy decoding — two confident distributions give TV near 0 (same bin) or near 1 (different bins); 81% of step-TVs lie outside (0.1, 0.9). Initial TV predicts the step-30 label with AUC 0.68 on all pairs and 0.60 on eligible pairs. E1 (token-persisted rerun with horizon stability and single-surface baselines) is running to determine if this is a real dynamical phenomenon or a greedy artifact.

**FRONTIER: State reconstruction (exp #52, 240 readouts; REVISED by Fable R4).** canonical_record and summary_nl produce TV=0 (tautological by design). Appended overwrite shows target_query 0.006→0.036 — the "6x amplification" is a ratio of near-zero numbers (absolute change 0.03, below tau=0.05). ortho_query 0.148→0.059 shows the overwrite doing what overwrites do. No valid repair arm exists in this

experiment design; finding should not be in STATE as established.

**DATA: nonvar_42 is NOT digit copying on base model (exp #59; MODEL MISMATCH with #48).** R4's digit-copying finding was on Qwen/Qwen3-1.7B (post-trained, exp #48). Exp #59 used Qwen/Qwen3-1.7B-Base. On Base: argmax is locked to the cell value regardless of continuation literal (leading-digit match 9.7%, identical argmax census 36/36). On post-trained (#48): `_ = 42` gives argmax "4" in 20/36, empty already at "9" in 23/36 — R4 was right for that model. These are DIFFERENT MODELS; neither refutes the other. "Digit-copying DEAD" was a cross-model comparison error. UNREPORTED #59 finding: identity (`x = x`) on Base flips argmax from correct outer value to "9" (nested-99999 attractor) in 18/36 readouts across 5/6 cells. Margin collapses from 0.42-0.81 to 0.01-0.42. Mechanism: two-basin competition between outer value and innermost-scope attractor, tipped by continuations.

**SYSTEMIC: Eligibility filter dropped after #46 (Fable R4).** Experiments #49/#50/#51/#42/#52 compute raw TV on all cells with no eligibility filter (d_pre <= tau). Omega is only defined on pairs that start close. Roughly half the cells have baseline TV 0.2-0.98. Several headline claims were eligibility artifacts. All claims since #46 must be reassessed on eligible cells only.

~28,000+ readouts across 65+ experiments, 5 architectures. NOTE: #48 and #49 are the same 288 readouts (double-counted in total). Effective n for consequence claims is 18 cell-pairs on one model. CRITICAL: experiments #48 (post-trained) and #59 (Base) use different models — cross-model comparisons require matching model_id.

**Codex mechanism review R1 (2026-09-17):** "Continue the program, but pivot from cataloguing amplifiers to testing whether omega predicts consequential failures prospectively. The amplification phenomenon survives; the proposed mechanism remains unidentified." Nine claims revised per review. Full review: experiments/results/codex_mechanism_r1.md

**Fable strategic review R4 (2026-09-17):** Withdraws gradient reversal, revival generality, 6x overwrite, identity paradox, digit-value-matters as eligibility or selection artifacts. r=0.677 survives with CI [0.47, 0.81] but is only modestly better than single-surface margin. Recommends cross-question transfer test and digit-prior sweep before any cross-model replication. Full review: experiments/results/fable_strategy_r4.md

**PROVISIONAL: Cross-question transfer hypothesis OPEN (exp #58, 35% complete).** Partial data (200/576 readouts, 2/6 cells) yields a Spearman hint (ρ=0.651, p=0.003, n=18 non-independent, single cell x=1) that TV ranks may correlate between assert_eq and print_output. No cross-cell evidence. Continuation and pair confounds unresolved (R7). Mean transfer AUC at chance (0.498). Fair margin also fails at transfer (0.386). Same-Q certificate: 0/49 violations. Addition shows no rank stability (ρ=-0.135, 0.057). Suffix-overlap rival ruled out. One asymmetric transfer AUC (0.922) rests on 1 flip — not evidence of discrimination. **Complete the experiment (remaining 4 cells) before concluding.**

**Fable strategic review R5 (2026-09-17):** Devastating provenance audit. #61 is n=32 reanalysis of #56, NOT 108 pairs. #62 AUC delta is fit noise (7 flips, no CV, F1=0 everywhere). Safety paradox WITHDRAWN (n=6, p=0.54, bugged panel). Bifurcation

DOWNGRADED: greedy-decoding/11-bin readout artifact pending token-persisted E1 rerun. Length scaling downgraded (n=6/point, no CIs, heavy decline has cheap explanation). Three priority experiments: E1 (token-persisted #56 rerun), E2 (null control + temperature), E3 (answer-level consequence). Cross-question #58 remains the only claim-bearing test. Full review: experiments/results/fable_strategy_r5.md

**FINDING: Margin dominates same-question flip prediction (exp #60b, #62b).** On Qwen3-1.7B-Base, 120 (cell, continuation) rows from exp #53 with 7 argmax flips, single-surface top-2 margin predicts same-readout flips with in-sample AUC 0.977 versus 0.838 for cross-surface TV. An in-sample logistic fit (no cross-validation, F1=0 for all models) shows no incremental value of TV over margin plus continuation type at this n. NOTE (R5): the AUC delta of -0.018 when adding omega is fit noise on 7 positives, not evidence of negative information. The defensible conclusion: omega does not add to margin for same-question prediction at this sample size.

**DATA: Length scaling (exp #57, n=6 cells per point, no CIs; DOWNGRADED by R5).** Over 0-12 repetitions on 6 cells per point without confidence intervals: nonvar (_=42) rises monotonically (0.029 to 0.121) — the one curve with no cheap explanation. Heavy (x=x+1) rises then declines (0.126 at n=2 to 0.077 at n=12), but repeated `x = x + 1` moves the correct answer to val+n (two digits for val>=5 at n>=5), so both surfaces converging on "1" explains the decline without dynamics. Identity (x=x) jumps at n=1, then wobbles 0.040-0.051. The nonvar log-growth curve merits a CI before it merits a claim.

**DATA: Bifurcation predictor (exp #61, CORRECTED by R5: n=32 reanalysis of #56, NOT 108 pairs).** On the 32 #56 trajectories, initial TV predicts the step-30 label with AUC 0.676 (95% CI approx [0.48, 0.87]). The 108-pair design was never run. Eligible-only (n=17, 8 grow): identity 3/3, heavy 1/1, empty 3/7, nonvar 1/6. The reported "identity 88% grow" rests mostly on ineligible cells.

**WITHDRAWN: Inverted safety paradox (R5).** Within strong_assert_2 (n=6, exp #38 panel), baseline TV and max omega have Spearman rho=-0.31 (p=0.54). The source panel has the R3 boundary bug, range restriction at the noise floor (baseline TVs span 0.0002-0.01), and max_omega has winner's curse (max over 14 continuations). Not established.

**FINDING: 11-bin ≡ full-vocab for code domain (exp #55b).** TV ratio 1.0004, identical 6 flips, same correlations. The 11-bin readout loses no information vs full vocabulary in code domain. No measurement artifact concern for existing claims.

**DATA: Continuation composition is non-commutative (exp #62, composition ordering).** Chaining two continuations produces TV that depends strongly on ORDER. neutral_then_identity (mean TV 0.100) is 2.1x identity alone (0.047) and 4x the reverse order identity_then_neutral (0.025). verified_then_bare (0.040) is 7.3x bare_then_verified (0.005). Amplification is real: several chains exceed the maximum of either single continuation. This is static omega data (not trajectory), showing that continuation sequence creates non-trivial interaction effects in the model's state. N=11 cells per condition.

**CRITICAL: Exp #49 data unreproducible (model behavior mismatch, 2026-09-17).** Fresh reproducer with identical code, model hash (ea980cb0), cell (x,1),

surface (minimal_ok), continuation (nonvar_42) gives P(1)=0.610 P(4)=0.206 (argmax=1, correct). #49 had P(1)=0.005 P(4)=0.760 (argmax=4, digit copying). KV cache deepcopy verified intact (3 identical results across 36 intervening calls). Full-forward matches KV (diff 1.31e-06). Tokenization verified identical. Weights unchanged since Feb 17 2026. Cause: likely transformers library update (now 5.12.1) changed attention computation. The AUC 0.918 result and the digit-copying phenomenon from #49 are unreproducible artifacts. All post-#54 experiments use the current version and show consistent behavior (argmax = cell value for all nonvar continuations). The 7 flips that drove AUC 0.918 were likely version-dependent.

**FINDING: Neither TV nor margin transfers across questions.** On 500-readout partial data from exp #58: cross-Q TV AUC 0.561 (near chance), cross-Q margin AUC ~0.49 (also chance). Argmax agreement under Q1 has near-zero sensitivity for Q2 flips. The transfer problem is fundamentally hard — no single-question measurement predicts behavior under a different question. This is a deeper negative than "omega fails."

Results: experiments/results/omega_*/. Reviews: experiments/results/fable_omega_review_{1,2,3,4}.md, fable_strategy_r4.md, fable_strategy_r5.md.

## HISTORICAL: TRHO: Transfer Rho Spectrum — behavioral non-verifiability (2026-09-17)

**What d measures (R21 clarification):** For each (cell, perturbation) pair, the two forward passes use the *minimal* surface (no header) and the *verbose* surface (`# Python code\n` header), both with the perturbation applied. d[cell, pert] is the cosine distance between those two full-logit vectors. The perturbation is the CONTEXT in which a fixed 4-token header edit is measured — it is never compared to the unperturbed prompt. The 24 "perturbations" are 24 contexts; d is header-sensitivity-in-a-context.

Transfer rho quantifies how well behavioral distances measured under one set of code perturbations predict behavioral distances under a different set. 5 model families (Qwen3-1.7B, SmolLM2-1.7B, Phi-1.5, StableLM-2-1.6B, CodeGen-350M), full-logit cosine readout, 40 expression-based cells, 24 perturbations (4 groups × 6), fp32 CPU. Scale ladder complete: SmolLM2-135M, SmolLM2-360M, Qwen3-0.6B (2026-09-18).

**R21 multiple-testing note:** >70 hypothesis tests in this section; no family-wise or FDR correction applied. Marginal results (p=0.007-0.05) should be interpreted with this in mind.

**Central finding (post-R19/R20/R21, corrected):** Behavioral sensitivity is predominantly **multiplicative**: d[i,j] ≈ cell_fragility[i] × pert_magnitude[j]. R21 notes this is first-order Taylor: median angle is 0.04-0.28 rad (small-angle regime), so d ~ theta²/2 where theta ~ gain(cell) × push(context). Any smooth model is multiplicative to first order. The CONTENT is entirely in the log-scale residual (12-25%).

On log scale, additive $R^2$=0.82-0.88. **$R^2$=1.000 claim RETRACTED:** the computation mixed raw-scale residuals with log-scale total SS (62M× inflated denominator). Correct raw-scale mult $R^2$ = 0.62-0.86; log-space $R^2$ = 0.82-0.88. That residual has **significant cell × group interaction in 7/8 models** (nested F + group-label permutation, log scale, 8-model extension):

Qwen3 p=0.0003, SmolLM2 p=0.0007, StableLM p=0.0003, CodeGen p=0.009, Phi p=0.31.
Group D perturbations do NOT cohere internally (within-D rho 0.22-0.76); the
group-level interaction is not separable from edit locus in this design.
(Prior "5/5 additive, type-blind" claim RETRACTED — R20 found the permutation test
was a null operation: whole-row permutation leaves ISS invariant, all p-values were
floating-point roundoff. Prior "2/5 transfer" also retracted per R19.)

**Scale ladder results (2026-09-18, CORRECTED 2026-09-19):**

| Model | Params | Gap | 95% CI | Acc | P(digit) | Perm Z | p |
|---|---|---|---|---|---|---|---|
| SmolLM2-135M | 135M | 0.121 | [0.065, 0.205] | 52.5% | 0.994 | 2.7 | 0.004 |
| SmolLM2-360M | 360M | 0.318 | [0.207, 0.431] | 90.0% | 0.993 | 6.0 | <0.001 |
| SmolLM2-1.7B | 1.7B | 0.281 | [0.197, 0.385] | 95.0% | — | 6.0 | <0.001 |
| SmolLM2-1.7B-Inst | 1.7B | 0.251 | [0.170, 0.339] | 94.4% | — | 3.2 | <0.001 |
| Qwen3-0.6B-Base | 0.6B | 0.087 | [0.052, 0.129] | 100% | 0.996 | 5.0 | <0.001 |
| Qwen3-0.6B (instruct) | 0.6B | 0.489 | [0.347, 0.628] | 100% | 1.000 | 8.8 | <0.001 |
| Qwen3-1.7B-Base | 1.7B | 0.452 | [0.315, 0.593] | 100% | — | 8.8 | <0.001 |

**SmolLM2 non-monotonic:** Gap peaks at 360M (0.318) then DECREASES at 1.7B (0.281).
Accuracy scales monotonically (52.5%→90%→95%). Gap-CIs overlap (R21 note: not
significant at n=3 scale points). Gradient exists at 135M with 52.5% accuracy (p=0.004).
**R23 CORRECTION (2026-09-19):** The 0.087 (Base) vs 0.489 (Instruct) comparison is a
definition artifact: "gap_fulllogit" was computed differently for the two files (within-minus-
between vs AA-minus-AD). Like-for-like comparison using the same metric (AA - AD): Base
0.324 → Instruct 0.489 = **1.5x** (paired CI [-0.004, +0.310]). The "5.6x" and "LARGEST
SINGLE EFFECT" claims are WITHDRAWN. **Replication on SmolLM2 (2026-09-19):** SmolLM2-1.7B
Base gap=0.281, Instruct gap=0.251 (0.89x). Gap amplification does NOT replicate —
the instruct effect is architecture-dependent.
**INSTRUCT CONFOUND — RESOLVED (2026-09-19).**
Base vs Instruct comparison (Qwen3-0.6B, same tokenizer, like-for-like gap):
**Base vs Instruct comparison (Qwen3-0.6B, same tokenizer):**

| Metric | Base | Instruct | Ratio |
|---|---|---|---|
| Gap (AA-AD, like-for-like) | 0.324 | 0.489 | 1.5x |
| Within-D rho | 0.394 | 0.169 | 2.3x |
| parens<->int_cast | 0.729 | 0.183 | 4.0x |
| Mean distance | 0.025 | 0.019 | 0.76x |
| PC1 share | 87.8% | 53.1% | — |
| Residual gap | 0.241 | 0.309 | — |
| Cross-variant fragility rho | 0.333 (p=0.036) | — | — |

Instruction tuning DESTROYS D-group internal coherence (0.394→0.169) and specifically
the parens<->int_cast coupling (0.729→0.183) despite identical tokenizer. Base model
has LARGER mean distances (0.025 vs 0.019) but LOWER gap — perturbation types are more
interchangeable in the Base model. Cross-variant fragility rho = 0.333: weak correlation

means instruction tuning reorganizes WHICH cells are fragile, not just how much.

**Residual gap (fragility-partialled) for scale ladder models:**

Qwen3-0.6B-Base: residual gap 0.241 [0.169, 0.307], PC1=87.8%. ALL GATES PASS.

R21 SUPPRESSOR CAUTION: PC1=87.8% is high; residual gap (0.241) exceeds raw gap (0.087) by 2.8x — same suppressor pattern as SmolLM2-360M (PC1=90.5%).

Qwen3-0.6B (instruct): residual gap 0.309 [0.115, 0.487], PC1=53.1%.

Qwen3-1.7B: residual gap 0.230 [0.077, 0.430], PC1=51.0%.

SmolLM2-1.7B: residual gap 0.310 [0.091, 0.533], PC1=78.2%.

SmolLM2-360M: residual gap 0.384 [0.205, 0.480], PC1=90.5%. R21 SUPPRESSOR WARNING.

SmolLM2-135M: residual gap 0.105 [-0.015, 0.251], PC1=69.6%. FAILS (CI incl 0).

**PC1 ordering (scale):** Qwen3-1.7B (51%) < Qwen3-0.6B-instruct (53%) << SmolLM2-135M (70%) < SmolLM2-1.7B (78%) < Qwen3-0.6B-Base (88%) < SmolLM2-360M (91%). Lower PC1 = more complex sensitivity structure beyond simple fragility. Base model has HIGHER fragility dominance than instruct — instruction tuning creates multi-dimensional sensitivity.

**Evidence for the surviving claim:**

- Same-type transfer (6 inert appends): rho 0.63-0.76, CIs exclude zero
- Novel inert held-out (3 new types): rho ~ 0, all p > 0.4
- Cross-type (surface -> semantic): Qwen3 CI [-0.03, +0.34], includes zero
- Within-semantic: Qwen3 CI [-0.004, +0.34], includes zero
- One-factor fragility model rejected in 4/5 model x readout combinations
- Cross-model fragility: rho=0.24 (code, NS) and -0.06 (NL, zero)

**WITHDRAWN claims (R13 triage):** "Qwen3 collapses in NL" (fp16 floor), "SmolLM2 domain-stable" (fragility-dependent), "Phi gap erasure code-specific" (precision mismatch), mac/sqrt(d_eff) (in-sample/tautological), "no negative correlations in full-logit" (false in NL), biology >> LLM (no backing data), d_eff as independent finding (restatement of correlation structure).

**RESOLVED: position confound (kill experiment, 2026-09-18).** Position contributes ~0.2 to the gap but does NOT explain it. Cross-position inerts (insertions before the assignment) transfer at rho=0.611 vs same-position inerts at 0.785-0.811. The remaining ~0.3 gap between cross-position inerts (0.611) and rewrites (0.333) is genuine: touching the computation path vs not touching it. Rewrites barely transfer to each other (0.224) — each probes a unique sensitivity dimension.

**Kill experiment results (Qwen3-1.7B, fp32 CPU, 40 cells x 24 perts; R14 REVIEWED):**

- Inert appends transfer as a class: a<->b = 0.811 (new inerts predict old inerts)
- Position is a PARTIAL confound (~35% of gap): a<->c = 0.611 vs a<->a = 0.785
- Gap IS real after position control: a<->d = 0.333 (rewrites don't transfer)
- Rewrites are NOT a coherent class: d<->d = 0.224 (std 0.250 > mean, includes negatives)
- Gradient: same-type (0.81) > cross-position (0.61) > cross-type (0.33) > within-rewrite (0.22)
- fp32 CONFIRMS 11-bin gradient (but doesn't fix full-logit magnitudes: 54% still < 1e-3)
- R14 CORRECTION: a<->b > a<->a (0.811 vs 0.785) is group-homogeneity noise, not evidence of "better than training" transfer — Group B is internally more homogeneous (std 0.064 vs 0.106)
- R14 CAVEAT: "computation path" interpretation is unfalsifiable as stated; conflated with syntactic novelty (Group D uses unusual syntax, A/B/C use common idioms). Needs syntactic novelty control experiment.
- Statistical significance: Mann-Whitney p=7.9e-13 (a<->b vs a<->d), p=2.1e-8 (a<->c vs a<->d)

- Bootstrap CIs (95%, cell resampling): a<->b [0.72, 0.86], a<->c [0.46, 0.71], a<->d [0.15, 0.47], d<->d [0.07, 0.37]
- Rewrites produce larger distances in 92% of cells (37/40) — not driven by a subset
- Within-rewrite negative correlations: d_temp_var<->d_add_zero = -0.328 (each rewrite probes a

UNIQUE dimension). Within-inert all rhos > 0.55 (all p < 0.001) — inerts ARE one class

**Transfer hierarchy (11-bin readout, POSITION-CONTROLLED by kill experiment):**

- Within-surface rho: 0.63-0.74 (trivial perturbations self-consistent)
- Cross-position same-type: ~0.57 (position contributes ~0.2 of the original gap)
- Cross-type rho: 0.08-0.37 (surface cannot predict semantic — CONFIRMED with controls)
- Within-semantic rho: 0.14-0.35 (structural changes are unpredictable)

**Effective dimensionality (model-independent at 11-bin):**

- Surface: ~1.87-1.89 effective dimensions (participation ratio)
- Semantic: ~4.05-4.23 effective dimensions
- Ratio 2.2x is MODEL-INDEPENDENT across Qwen3 and SmolLM2
- PC3/PC4 of semantic are nearly orthogonal to surface (2-4% overlap)

**1/sqrt(d_eff) theoretical bound:**

- Matches surface rho within 2% (predicted 0.731, observed 0.718)
- Overshoots semantic by 3.7x (predicted 0.497, observed 0.135)
- The excess = adversarial structure in semantic perturbation interactions

**Mechanistic source — perturbation correlations:**

- Surface: all pairwise correlations positive (min 0.38-0.48)
- Qwen semantic: 3 NEGATIVE correlation pairs (min r=-0.30)
- SmolLM2 semantic: zero negative pairs but all weak (min 0.01)
- Negative correlation means learning one semantic effect MISLEADS about another

**Full-logit readout vs 11-bin — gap is MODEL-SPECIFIC:**

- Qwen3 full-logit: surf=0.661, sem=0.227 (gap PRESERVED, ratio 2.0x)
- SmolLM2 full-logit: surf=0.760, sem=0.511 (gap REDUCED, ratio 1.8x)
- Phi-1.5 full-logit: surf=0.696, sem=0.662 (gap ERASED, ratio 1.05x)
- Phi-1.5 (code-trained) has semantic dimensionality 1.07x surface
- Code-specific training may reduce semantic perturbation dimensionality

**Non-Euclidean geometry hypothesis: NEGATIVE.**

Triangle inequality satisfied. All perturbation angles acute (5.7-35.5 deg).

Gromov hyperbolicity test shows weakly positive curvature (not hyperbolic).

Cross-space distance Spearman 0.35-0.55 (moderate, not degenerate).

The non-transfer comes from signal structure (heterogeneous cell sensitivity

patterns), not from non-Euclidean geometry of the perturbation space.

**Bootstrap CIs (500 iterations, cell resampling):**

- Qwen cross-type 11-bin: [-0.031, 0.341] — includes zero
- SmolLM2 cross-type 11-bin: [0.185, 0.709] — excludes zero
- All within-surface CIs exclude zero
- Qwen full-logit: surf [0.427, 0.848], sem [0.032, 0.540]

**Noise calibration:** Deterministic TV=0.0, permutation p<0.001, 4.9sigma.

**NL generalization (Qwen3-1.7B-Base, GPU):**

NL math uses the same arithmetic problems in question format instead of code.

100% engagement (accuracy 1.0, P(digit)=0.999). ALL rho values collapse:

- 11-bin: surface 0.518 (vs 0.685 code), semantic 0.094 (vs 0.309 code)
- Full-logit: surface 0.175 (vs 0.661 code), semantic 0.048 (vs 0.227 code)

- NL surface dimensionality: 3.81 (vs 1.62 code) — every NL word is semantic
- Dimensionality ratio: 1.44x (vs 1.99x code) — NL surface is also high-dim

Implication: code's strict syntax creates a uniquely clean surface/semantic separation. NL has NO genuinely trivial perturbation class. Code alignment is partially certifiable; NL alignment is uncertifiable at this granularity.

**Perturbation transfer matrix (full-logit, zero-cost analysis):**

- Qwen sem-sem mean rho=0.361, worst pair varname_y<->assign_twice at 0.044
- SmolLM2 sem-sem mean rho=0.613; Phi-1.5 sem-sem mean rho=0.754
- Phi-1.5's gap erasure comes from HIGH within-semantic correlation, not low surface
- No negative correlations in full-logit; 11-bin negatives are readout artifacts
- func_call is universally the lowest-correlated semantic perturbation

**Common-factor null (fragility control):**

Fragility (per-cell mean TV) accounts for 55-90% of raw rho. After partialling out fragility: Qwen gap AMPLIFIES (surf partial rho 0.39-0.73, sem 0.07 to -0.24); SmolLM2 gap shrinks; Phi-1.5 semantic > surface. The confound was real but the Qwen finding is STRONGER with the control.

**NL multi-model comparison (full-logit, confirmed):**

- Phi-1.5: gap erasure is CODE-SPECIFIC. Code ratio 1.05x -> NL ratio 1.82x
- SmolLM2: DOMAIN-STABLE. Code ratio 1.49x -> NL ratio 1.50x (unchanged!)
- Qwen3: COLLAPSES in NL. Surface 0.661->0.175, semantic 0.227->0.048
- Model ordering reverses in NL: SmolLM2 (0.492) > Phi-1.5 (0.338) > Qwen3 (0.048)
- Phi-1.5 has P(digit)=0.001 in NL (11-bin unreliable); full-logit valid

**Improved theoretical bound: rho ~ mac / sqrt(d_eff).**

mac = mean absolute pairwise Spearman correlation between perturbation effects. mac/sqrt(d_eff) has mean error 6.7% vs 15.6% for 1/sqrt(d_eff) alone. Qwen3 semantic: 11% error (vs 146% for 1/sqrt alone). The formula captures both pathway-sharing structure (mac) and dimensionality (d_eff). All three predictors (1/sqrt, mac, mac/sqrt) rank-order the models correctly (n=6).

**Cross-domain fragility decomposition (NL vs code):**

Fragility loading patterns are MODEL×DOMAIN specific — the same model allocates fragility differently in code vs NL:

- Qwen3 CODE: fragility dominates both surface (R2=88%) and semantic (R2=83%)
- Qwen3 NL: fragility barely touches surface (R2=0.6%) but dominates semantic (R2=92%)
- SmolLM2 CODE: surface fragility (R2=94%), low semantic fragility (R2=30%)
- SmolLM2 NL: fragility dominates both (R2=80-90%)

After removing fragility, the partial gap is CONSERVED for Qwen3: +0.255 (code) vs +0.256 (NL). The gap is an architectural invariant even though what fragility captures changes completely between domains. SmolLM2 code retains genuine semantic structure (partial rho=0.377); SmolLM2 NL collapses entirely.

**StableLM-2-1.6B (4th architecture family, PARTIAL):**

- Code full-logit: surf=0.918, cross=0.763, sem=0.827 (ratio 0.97x — NO GAP)
- Code 11-bin: surf=0.735, cross=0.419, sem=0.406 (ratio 1.36x)
- NL full-logit: surf=0.640, cross=0.443, sem=0.206 (ratio 1.91x — HUGE gap)
- NL 11-bin: surf=0.612, cross=0.091, sem=0.025 (ratio 1.55x)
- Pattern: code gap erasure (like Phi-1.5), NL gap massive (1.91x)

Falcon-H1-1.5B (hybrid SSM-attention, 5th family) running.

**SmolLM2-1.7B kill experiment replication (2026-09-18):**

- GRADIENT REPLICATES: same-type (0.86) > cross-position (0.67) > cross-type (0.58) > within-rewrite (0.44)
- Gap COMPRESSED vs Qwen3: a<->a minus a<->d = 0.281 (SmolLM2) vs 0.452 (Qwen3)
- ZERO distances below 1e-3 in full-logit — no fp16/fp32 floor concern whatsoever
- 95% accuracy (2 cells wrong)

**Phi-1.5 kill experiment (2026-09-18, Q0: NO GRADIENT; Q1: GRADIENT CONFIRMED — readout artifact):**

- Full-logit: a<->a=0.807, a<->d=0.752, d<->d=0.763. All rhos ~ 0.7-0.8. MWU p=0.52 (NS)
- Rewrites transfer to inerts AND to each other — no perturbation type boundary
- **P(digit) VERIFIED NEAR-ZERO (R15 condition resolved):** Sum P(any digit) = 0.0006-0.0028

across test cells. Model assigns 97-99% probability to NEWLINE, not digits. The "92.5% accuracy"
is argmax within the digit bins (correct ordering of <0.3% probability mass) — NOT meaningful
task engagement. Phi does not predict digits; it predicts code continuation (newline)

- **11-bin INVALIDATED:** 84% distances < 1e-3 is EXPLAINED by P(digit) near zero (noise on noise).

All Phi 11-bin rhos are unreliable and should be disregarded

- **Full-logit no-gradient SURVIVES:** Cosine distances (0.002-0.004 range) are on the full 51K-dim

logit vector, dominated by non-digit tokens. The model IS sensitive to perturbations on the
full distribution; it just doesn't differentiate between perturbation TYPES

- Phi's RII=0.763 (full-logit) measures consistency of perturbation effects on code-continuation

behavior, not on digit prediction — a fundamentally different measurement than the other models

- R15: "code-specialized training" attribution is confounded with architecture (parallel attn),

tokenizer (GPT-2 BPE, 51k vocab), model size (1.3B vs 1.7B), and training volume

**MODEL-DEPENDENT gradient (kill experiment, 5 architectures + Base/Instruct variant, IDENTICAL cells):**

- Qwen3-0.6B (instruct, 100% acc): STRONGEST gradient, gap 0.489 [0.347, 0.628], Z=8.8
- Qwen3-1.7B-Base (general, 100% acc): STRONG gradient, a<->d=0.333 << a<->a=0.785 (gap 0.452)
- CodeGen-350M-mono (code, 32.5% acc): GRADIENT, a<->d=0.444, a<->a=0.762 (gap 0.318, MWU p=2.3e-7)
- SmolLM2-1.7B (general, 95% acc): COMPRESSED gradient, a<->d=0.583, a<->a=0.864 (gap 0.281)
- StableLM-2-1.6B (general, 82.5% acc): MODERATE gradient, a<->d=0.628, a<->a=0.927 (gap 0.299, MWU p=4.5e-13)
- Phi-1.5 (code, 92.5%/95% acc Q0/Q1): NO gradient under Q0 (gap 0.055); **GRADIENT UNDER Q1

(digit-predicting readout): gap 0.217 [0.123, 0.355], p=5.26e-11, Z=4.6, residual gap
0.386 [0.171, 0.564]. ALL GATES PASS.** Q0 no-gradient was a READOUT ARTIFACT:
P(digit)=0.001 under Q0, 0.980 under Q1. Model-specific: Q1 inadmissible on Qwen3

- **Qwen3-0.6B-Base (general, 100% acc): WEAK gradient, gap 0.087 [0.052, 0.129], Z=5.0.**

LOWEST gap of any model with 100% accuracy. a<->a=0.910, a<->d=0.586, d<->d=0.394.
Residual gap 0.241 [0.169, 0.307], PC1=87.8%. ALL GATES PASS.
Like-for-like gap: 0.324 (1.5x lower than instruct 0.489; R23-corrected from 5.6x).

- All use the same 40 expression-based cells, 24 perturbations, fp32 CPU — no cell-design confound
- **Instruct effect (n=1 pair):** Qwen3-0.6B-Base (0.324 like-for-like) vs instruct (0.489).

1.5x amplification.
**SmolLM2-1.7B (second family):** Base gap=0.281, Instruct gap=0.251, ratio=0.89x.
SmolLM2 shows NO gap amplification. All distances increase uniformly (1.9-2.8x).
**Instruction tuning effect on gap is ARCHITECTURE-DEPENDENT, not general.**
Cross-variant fragility: SmolLM2 rho=0.689 (strong) vs Qwen3 rho=0.333 (weak).
SmolLM2 preserves its fragility fingerprint across instruction tuning; Qwen3 doesn't.

- CodeGen-350M 11-bin is dead (100% distances < 1e-3, near-zero digit probability);

only full-logit valid. 32.5% accuracy means task incompetence is a major confound

- StableLM has highest a<->a (0.927) and a<->b (0.937) — strongest inert transfer,

yet still drops to 0.628 for rewrites. Strong baseline ≠ strong cross-type transfer

 R15: "code-specialized → no gradient" REFUTED by CodeGen-350M (code-trained, gradient present). Phi's no-gradient is confounded with architecture, tokenizer, scale, accuracy, and training volume — cannot be attributed to code-specialization alone

**REWRITE INTERCHANGEABILITY INDEX (RII = within-group-D Spearman correlation):**

 Phi-1.5: RII=0.763 (but P(digit)≈0; measures code-continuation, not digit prediction)

 StableLM-2: RII=0.566

 SmolLM2: RII=0.443

 CodeGen-350M: RII=0.368 (P(digit)≈0 like Phi, but STILL shows gradient — refutes "not doing the task" as explanation for Phi's no-gradient)

 Qwen3: RII=0.224 (includes negatives)

 **MEASUREMENT SURFACE NOTE:** Phi and CodeGen put near-zero probability on digit tokens (P(digit) ≈ 0.001 and ≈ 0 respectively); their 11-bin readout is noise. Qwen3/SmolLM2/StableLM genuinely predict digits (11-bin median distance 0.015-0.094, 0% below 1e-3). However, the gradient and RII are computed on FULL-LOGIT cosine distance (full vocabulary vector), which captures whatever the model IS doing regardless of which tokens carry probability. The full-logit comparison is valid across all 5 models. The confound applies ONLY to 11-bin readout

 RII vs gradient (all 5 models, n=5): Pearson r=-0.944 (p=0.016), Spearman r=-0.900 (p=0.037)

 RII vs gradient (4 comparable 1.3-1.7B models, n=4): Pearson r=-0.952 (p=0.048)

 RII vs gradient (3 digit-predicting models only, n=3): Pearson r=-0.897 (p=0.29, underpowered)

 R16 E-corrected: RII is ~50-78% fragility share; this correlation should be read as fragility-share vs gradient. n=5, no CI. The GAP (not RII) is the perturbation-type-specific quantity that survives fragility removal

 R15 CORRECTION: causal attribution ("code-specialized → high RII") was OVERREACH. The correlation is empirical; the driver is unknown (training data, scale, architecture, measurement surface, or some combination). RII is a descriptive index, not a causal mechanism

 **RETRACTED: z-RII / FDI (R16 R2 — null artifact).** z-scored RII ≈ -0.18 is the expected pairwise Spearman after row-centering k=6 columns (-1/(k-1) = -0.20; pure noise gives -0.192). FDI = RII + 0.18 is a constant shift; FDI vs gap r=-0.952 is the existing RII vs gap relabeled. All z-RII/FDI claims withdrawn

 **FRAGILITY-PARTIALLED GROUP RHOS (R16 E-corrected, rank regression on per-cell mean distance):** PC1 (common fragility) share: Qwen3 51%, CodeGen 58%, Phi 73%, StableLM 77%, SmolLM2 78%. Residual RII collapses to 0.05-0.13 for all 5 models (vs raw 0.22-0.76, range 0.11 vs 0.54); analytic baseline -1/(k-1) ≈ -0.04 to -0.10 depending on PC1 share (not zero). Cross-model RII differences are mostly fragility-share differences. But the GAP SURVIVES partialling:

**Raw gap CIs (bootstrap 95%, 1000 resamples):**

Qwen3 +0.452 [+0.315, +0.593], CodeGen +0.318 [+0.202, +0.436], StableLM +0.299 [+0.191, +0.438], SmolLM2 +0.281 [+0.197, +0.385] — all exclude 0. Phi Q0 +0.055 [+0.005, +0.106] barely excludes 0.

**Residual gap CIs (fragility-partialled):**

Qwen3 +0.230 [+0.077, +0.430], CodeGen +0.277 [+0.100, +0.421], StableLM +0.560 [+0.256, +0.750], SmolLM2 +0.310 [+0.091, +0.533] — all exclude 0. Phi Q0 +0.005 [-0.076, +0.110] includes 0 (NS).

Residual RII near zero for all models (CIs all include or touch 0): Qwen3 +0.062 [-0.037, +0.142], SmolLM2 +0.051 [-0.046, +0.164], StableLM +0.061 [-0.027, +0.218], CodeGen +0.078 [-0.025, +0.197].

Exception: Phi +0.125 [+0.029, +0.263] — the only model with residual RII excluding 0.

**Permutation null for residual RII:** Qwen3 bias-corrected +0.099 (>null 97.5th), SmolLM2 +0.071 (within null), StableLM +0.078 (within null), Phi +0.142 (>null 97.5th),

CodeGen +0.118 (>null 97.5th). Phi's high residual RII is genuine, not a partialling artifact.
The gradient is not a common-factor artifact; Phi's absent Q0 gradient is not fragility-masked
but IS a readout artifact (see PHI READOUT SATURATION).
**Phi Q1 fragility partialling COMPLETED:** residual gap +0.386 [+0.171, +0.564] excl 0.
PC1 share 84.6%. Despite highest fragility share, Phi Q1 has SECOND HIGHEST residual gap.
Residual RII under Q1: 0.219. All 5 models now have residual gap CIs excluding 0 under
admissible readouts

 **PHI READOUT SATURATION — CONFIRMED (R16 Step 1 + R18 restructure, 2026-09-18):**
Removing ONE trailing space from the query (`# Output: ` → `# Output:`) flips Phi from
code continuation (P(digit)=0.001) to full digit prediction (P(digit)=0.980, accuracy 95%).
Tokenizer mechanism: Q0 ends on space token (→ newline prediction), Q1 ends on colon token
(→ digit prediction). Phi KNOWS the answer but outputs newline instead of digit under Q0.
**PRIMARY RESULT (40-cell kill-matched, Q1 query, same cells as other 4 models):**
gap=0.217, CI [0.123, 0.355], p=5.26e-11. P(digit)=0.980, accuracy=95%.
a↔a=0.899, a↔d=0.682. Pre-registered gates PASS (gap ≥ 0.20 AND CI excludes 0.10).
Q0 control on same 40 cells: gap=0.055 [0.010, 0.106] — EXACT MATCH to original kill.
**SUPPLEMENTARY (20-cell, different cells/surfaces — NOT directly comparable to kill):**
gap=0.335, CI [0.141, 0.494], p=8.76e-9. 20 varied-variable-name cells, surfaces
"" vs "# init\n" (not kill surfaces). P(digit)=0.843, accuracy=85%. Larger gap partly
explained by different cell design, surface pair, and lower accuracy. a<->a=0.728, a<->d=0.393.
RII under Q1: 0.235 [0.051, 0.412].
**STATUS: 5/5 CONFIRMED (R18 definitive test, 2026-09-18).** Phi Q1 40-cell passes ALL gates:
(1) gap 0.217 >= 0.20 PASS, (2) CI [0.123, 0.355] lower > 0.10 PASS,
(3) permutation null Z=4.6 (p<0.001) > 2 PASS, (4) residual gap 0.386 [0.171, 0.564] excl 0 PASS.
PC1 share 84.6% — high fragility, but type-specific signal survives. Residual gap (0.386) is
the SECOND HIGHEST after StableLM (0.560), ABOVE Qwen3 (0.230) and CodeGen (0.277).
Raw gap ordering: Qwen3 (0.452) > CodeGen (0.318) > StableLM (0.299) > SmolLM2 (0.281) > Phi-Q1 (0.217).
Residual ordering: StableLM (0.560) > Phi-Q1 (0.386) > SmolLM2 (0.310) > CodeGen (0.277) > Qwen3 (0.230).
All 5 confirmed under their admissible readouts. Phi requires model-specific Q1 correction
(inadmissible on Qwen3). "5/5 under model-specific admissible readouts" is the honest framing.
**QWEN3 Q1 CONTROL:** Q1 is INADMISSIBLE on Qwen3 (P(digit)=0.019, 0% cells ≥ 0.5).
The trailing-space effect is MODEL-SPECIFIC and OPPOSITE: Phi needs no-space (Q1) to predict
digits; Qwen3 needs space (Q0). Cross-model magnitude comparison confounded by readout mode

 **PERMUTATION NULL (independent confirmation, 2026-09-18):**
Shuffle perturbation labels within each cell (500 permutations). Under null: only fragility
matters. Results (Q0): Qwen3 Z=8.8, SmolLM2 Z=6.0, StableLM Z=6.2, CodeGen Z=5.5 (all p<0.001).
Phi Q0 Z=1.0 (p=0.168, NOT significant — readout artifact). **Phi Q1 Z=4.6 (p<0.001) — CONFIRMED.**
All 5 models pass permutation null under their admissible readouts.
Permutation 95th percentile approx 0.08-0.10 for all models; any real gap exceeds this by 2.5-5x

 **P(DIGIT) VERIFICATION (from 11-bin distance magnitudes, no model loading):**
Qwen3: median 0.015 (0% < 1e-3, DIGIT). SmolLM2: 0.094 (0%, DIGIT). StableLM: 0.089 (0%, DIGIT).
Phi: 0.0003 (83%, CODE CONTINUATION). CodeGen: 0.00001 (100%, CODE CONTINUATION).
Clean binary split confirms 11-bin is INVALID for Phi/CodeGen; full-logit valid for all

 **DIGIT-CONCENTRATION HYPOTHESIS TEST (R18 Reading B, zero-cost, 2026-09-18):**
If the gradient were purely P(digit)-driven concentration, 11-bin (digit-only) gap should be

≥ full-logit gap. Observed 11-bin/full-logit gap ratios: Qwen3 0.79 (11-bin SMALLER), SmolLM2 1.33, StableLM 1.13, Phi-Q0 1.57, CodeGen 0.60 (11-bin MUCH smaller). **REFUTED at comparative level:** CodeGen has full-logit gap 0.318 despite P(digit)≈0 — the gradient lives in the non-digit logit space. Qwen3 has full-logit gap (0.452) > 11-bin gap (0.359) — non-digit dimensions carry ADDITIONAL signal. The gradient is NOT purely digit-concentration. Definitive test (masking digit dims from logit vector) requires model loads.

 **CELL-EXCLUSION ROBUSTNESS (all 5 models, 2026-09-18):**
Phi L3O exhaustive (9,880 triples): max gap 0.077 — no cell subset creates a gradient. Gradient models L3O (2,000 random triples): min gap Qwen3 0.387, SmolLM2 0.232, StableLM 0.238, CodeGen 0.255 — gradient never collapses under any cell exclusion

 **COPY CONTROL — GRADIENT IS SURFACE SENSITIVITY (2026-09-19):**
40 literal-assignment cells (x=5, y=3, etc.) under same 24 perturbations per model.

| Model | Copy Gap | CI | Expr Gap | Ratio | H_surface | Admissible |
|---|---|---|---|---|---|---|
| Qwen3-1.7B | 0.403 | [0.288, 0.516] | 0.452 | 89% | PASS (0.049) | YES |
| SmolLM2-1.7B | 0.386 | [0.261, 0.527] | 0.281 | 137% | PASS (0.105) | YES |
| StableLM-2-1.6B | 0.193 | [0.094, 0.315] | 0.299 | 65% | PASS (0.106) | YES |
| CodeGen-350M | 0.241 | [0.163, 0.337] | 0.318 | 76% | PASS (0.077) | NO (70% acc) |
| Phi-1.5 | 0.197 | [0.115, 0.281] | 0.217 | 91% | PASS (0.020) | NO (P(digit)=0.001) |

**5/5 models tested. Series COMPLETE.** H_surface/H_compute binary thresholds DEPRECATED (see R22 correction below). StableLM: indeterminate (ratio CI [0.31, 1.05] includes both 0.5 and 1.0). Phi copy control run under inadmissible Q0 readout (Q1 was available).
**R22 CORRECTION (ratio bootstrap CIs):** All ratio CIs include 1.0: Qwen3 0.89 [0.64, 1.14], SmolLM2 1.37 [0.93, 1.87], StableLM 0.65 [0.31, 1.05]. Copy and expression gaps are statistically INDISTINGUISHABLE at 95% for all 3 admissible models. SmolLM2 ratio>1 is NOT significant — "computation-as-shielding" unsupported. Binary H_surface/H_compute thresholds DEPRECATED in favor of CI overlap. Phi NOT admissible (P(digit)=0.001). CodeGen NOT admissible (70% accuracy). 3/5 admissible models all show ratio CIs including 1.0.

 **POSITION vs CONTENT — R22 WITHDRAWN AS STATED (zero-cost, 2026-09-19):**
Original: same-position/diff-content 0.705 vs same-content/diff-position 0.530 (+0.175). **R22 correction:** The +0.175 is entirely the A/B after-block cohesion (already known from R13-R14). Balanced before-only comparison: mean +0.02, position wins 2/7, content 2/7. Content-matched cross-position pairs are NO MORE correlated than unmatched ones in 5/7 models (e.g. Qwen3-1.7B matched=0.607, unmatched=0.614). Content identity is UNDETECTABLE. Three confounds: header adjacency (C sits adjacent to measured edit), magnitude floor (C has smallest-magnitude perturbations), communality attenuation. "Position dominates content" WITHDRAWN; replaced with: "after-inerts form one class; content identity is undetectable; position vs header-adjacency not yet separable."

 **LOCUS ZERO-COST — R22 WITHDRAWN (zero-cost, 2026-09-19):**
Original: same-line inerts +0.070 more D-correlated (7/7 positive, 2/7 significant). **R22 correction:** "Different-line" pool included the 6 C perturbations (whose low D-correlation is the best-established fact in the program). Against A/B inerts only: +0.037, 1/7 significant, exact-permutation floor p=0.018. Same-line inerts are within 0.015 of a_empty (unperturbed baseline) in 7/9 models — they ARE the baseline, not

"more D-like". For Qwen3, a_whitespace is token-identical to a_empty (R17). WITHDRAWN.

 **REPLAY NOISE FLOOR — REPLAY-DETERMINISTIC; NOT A TEST OF RANK STABILITY (2026-09-19, R22+R23 correction):**

| Model | Noise max | Actual min | SNR | Verdict |
|---|---|---|---|---|
| Qwen3-1.7B | 3.1e-6 | 1.29e-4 | 316× | CLEAN |
| SmolLM2-135M | 3.6e-7 | 1.56e-4 | 10,408× | CLEAN |

Both largest (Qwen3) and smallest (SmolLM2-135M) models: 0% of kill experiment distances
below replay noise. Smaller model has LOWER noise (fewer params → less fp32 non-determinism).
All kill experiment measurements are well above fp32 replay noise.

 **POSITION SHIFT MECHANISM TEST — NULL RESULT (zero-cost, 7 models, 2026-09-19):**
If absolute token-count shift caused the position effect, C pairs with similar shift
(same tokens added) should correlate more. Test: Spearman(shift_diff, C-pair rho) across
all 15 C pairs per model. Grand correlation r=0.010 (p=0.918, n=105 pooled pairs). NULL.
5/7 models have NEGATIVE correlation. SmolLM2-1.7B: r=0.655 but highest C pair has LARGEST
shift difference (shift=4, rho=0.875) — OPPOSITE of prediction. Position organization is
QUALITATIVE (before vs after the assignment in causal attention window), not QUANTITATIVE
(how many tokens shift the position). Mechanism is causal attention asymmetry: before-
perturbations enter the assignment's attention context; after-perturbations don't.

 **INSTRUCTION TUNING EFFECT — R22 WITHDRAWN + REPLICATION FAILED (2026-09-19):**
**Qwen3-0.6B** (original claim): Gap UP 0.324→0.489, A↔C UP, A↔D DOWN, D↔D DOWN.
**R22 correction:** Paired-cell bootstrap: only decreases significant (A↔A -0.12, A↔D -0.28,
D↔D -0.22); A↔C "up" is +0.09 [-0.11, +0.29] NS; gap marginal under one definition,
null under the other. Base PC1=0.69 vs IT 0.59 → higher base A↔D is common-factor inflation.
**SmolLM2-1.7B REPLICATION (this session):** ALL correlations DROP uniformly.

| Metric | SmolLM2 Base | SmolLM2 IT | Qwen3 Base | Qwen3 IT |
|---|---|---|---|---|
| a↔a | 0.864 | 0.748 (DOWN) | 0.910 | 0.876 (DOWN) |
| a↔c | 0.672 | 0.480 (DOWN) | 0.410 | 0.503 (UP?) |
| a↔d | 0.583 | 0.497 (DOWN) | 0.586 | 0.301 (DOWN) |
| d↔d | 0.443 | 0.323 (DOWN) | 0.394 | 0.169 (DOWN) |
| Gap | 0.281 | 0.251 (DOWN) | 0.324 | 0.489 (UP) |

SmolLM2 IT uniformly decorrelates; gap goes DOWN. OPPOSITE of Qwen3. "Selective reshaping"
and "IT amplifies gradient" WITHDRAWN. Correct statement: "In both pairs, IT lowers most
correlations; gap direction is model-specific (Qwen3 up, SmolLM2 down); n=2 pairs."

 **SPACE-TOKEN CONFOUND — DISMISSED (zero-cost, 7 models, 2026-09-19):**
R21 flagged parens/int_cast share space-token deletion, top-3 D pair in 5/8 models.
Test: Jaccard similarity of token-level changes vs behavioral D-pair correlation.
Grand r=0.094 (p=0.340, n=105). NULL. Tokenization similarity does NOT predict behavioral
correlation. Critical control: add_zero/zero_plus have Jaccard=1.0 (IDENTICAL token changes)
but behavioral rho=0.023-0.777 — wildly inconsistent. If tokenization drove D-coherence,
this pair should always be top. It's not. parens/int_cast coincidentally share both
tokenization similarity and high behavioral correlation, but the pattern doesn't generalize.
One exception: Qwen3-1.7B shows r=0.523 (p=0.045) — model-specific, not general.

 **RETRACTED: COPY-VS-COMPUTE CONTROL (R17 Finding 1 — cell-schema mismatch):**

`copy_vs_compute.py` mapped rows using the 20-cell `make_cells()` schema from `run_transfer_spectrum.py`, but all five kill JSONs use 40 cells from `kill_experiment*.py` where ALL cells are `x = <arithmetic expr>` (zero literal-copy cells). The "simple/complex" split was an arbitrary answer-digit partition, not a computation-type split. The cell labels in STATE.md were factually false. Additionally, the 12-cell gap sits within the random-12 null distribution (48th-88th percentile), and the MWU tested amplitude difference not the rho gap. All copy-vs-compute claims WITHDRAWN. Process violation: entered STATE.md without review pass, violating R16 recommendations

**TRANSFER RHO (zero-cost reanalysis of kill experiment data, 2026-09-18):**
**Definition of d (R21 correction):** d[cell, perturbation] is the cosine distance between two forward passes: the minimal surface (no header) and the verbose surface (`# Python code\n` header, exactly 4 tokens in every condition), BOTH with the perturbation applied. The perturbation is a CONTEXT in which the fixed header edit is measured, not the edit being measured. The 24 perturbations are 24 contexts; d measures how much the 4-token header moves the readout given a cell and surrounding context.
Split: Group A (inert appends + unperturbed baseline) vs Group D (meaning-preserving rewrites). Transfer rho = Spearman(A-sensitivity, D-sensitivity) across 40 cells.

- **Raw transfer rho: 0.56-0.92** — real and driven by common fragility (all methods agree). Cells that are cross-surface fragile are fragile under every perturbation family.
- **Same-locus inert exchangeability:** A→B residual 0.83-0.97 in all 5 models under every covariate. Appends of the same locus are practically interchangeable.
- **RETRACTED: "2/5 models show type-specific transfer" (R19 review, 2026-09-18).** The B+C-PC1 partialled results (Qwen3 0.536, StableLM 0.565) were a forking-paths artifact:
(a) StableLM's 0.57 flips to -0.42 under rank partialling; one outlier cell (10%2, distance 0.59, 6 SD leverage) drives the sign. Refit-BCa CI [-0.07, 0.87] includes 0.
(b) Qwen3's 0.54 drops to 0.00 under rank + PC1+PC2. Within-operator strata show Simpson mixture: %: -0.89, +: 0.73. Cross-type exceeds within-D reliability (0.32).
(c) The 2/5 vs 3/5 split is COVARIATE COMPOSITION: C-PC1 gives all 5 models [0.30, 0.65]; B-PC1 gives all 5 [-0.12, 0.42]. B+C-PC1 is a per-model blend; which models pass depends on the blend, not on genuine transfer differences.
(d) Group A contains a_empty (the unperturbed baseline); rho(a_empty, rest of A) = 0.87-0.99. "Inert-append sensitivity" IS baseline fragility. Not a perturbation type.
(e) Power 0.43 at rho=0.3, n=40. Cannot claim null either. Need ~113 cells.
(f) "Model-dependent" was never tested (best Fisher z: p~0.06, no correction).
All-PC1 anti-transfer was also a suppression artifact (retracted earlier).
- **NEW FINDING: Fragility has a second edit-locus dimension** (8-17% z-scored variance). PC2 loads as before-insert vs at/after-assignment. One-PC partialling leaves this behind.
After removing both dimensions (PC1+PC2): zero of five models shows residual A→D transfer.
- **Defensible statement:** Cross-surface sensitivity is dominated by cell-level fragility (PC1, 62-73% variance) plus a second factor tied to edit locus (PC2, 8-17%). After removing both, no model shows a residual A→D correlation distinguishable from zero at n=40. The experiment as currently designed cannot establish or refute type-specific transfer; it establishes that same-locus inert appends are exchangeable (ρ 0.83-0.97).
- **Method instability table (A→D partial, B+C-PC1 unless noted):**
Qwen3: 0.54 / rank 0.36 / log 0.33 / PC1+2 0.22 / +operator 0.14 / rank-PC1+2 0.00

SmolLM2: -0.18 / rank 0.21 / log -0.11 / PC1+2 0.13 / +operator 0.05 (robust null)

StableLM: 0.57 / rank -0.42 / log -0.11 / PC1+2 0.17 / +operator 0.55 (unstable)

Phi: 0.16 / rank 0.41 / log 0.02 / PC1+2 -0.15 / +operator 0.39

CodeGen: 0.15 / rank 0.07 / log 0.08 / PC1+2 0.58 / +operator 0.27

No model ordering is stable across methods.

 **RETRACTED: Row-permutation interaction test (2026-09-19, retracted same day by R20).**
An interaction permutation test permuted whole rows of the distance matrix. The interaction SS is invariant under row relabelling (row means travel with rows, column/grand means unchanged). All 20 p-values were floating-point artifacts (null_std ~ 1e-20). The "5/5 additive", "type-blind", "monolithic fragility" claims are all withdrawn. Process failure: null_std should have been a stop signal. See experiments/results/fable_strategy_r20.md for full derivation.

 **CORRECTLY SPECIFIED TEST (R20 nested F + group-label permutation, log scale):**
**4/5 models show significant cell × perturbation-group interaction.**

| Model | cell% | pert% | resid% | cell×group share | nested F p | group-perm p |
|---|---|---|---|---|---|---|
| Qwen3 | 19.3 | 66.1 | 14.6 | 0.31 | 1e-19 | 0.0003 |
| SmolLM2 | 39.5 | 42.1 | 18.5 | 0.32 | 8e-21 | 0.0007 |
| StableLM | 45.7 | 37.1 | 17.2 | 0.40 | 9e-36 | 0.0003 |
| CodeGen | 12.6 | 74.9 | 12.4 | 0.26 | 3e-11 | 0.009 |
| Phi Q0 | 31.8 | 55.5 | 12.7 | 0.15 | 0.17 | 0.31 |

Under H0 (no cell×group), expected share is 117/897 = 0.13. Four models at 0.26-0.40. Phi at 0.15 (null). Power of this test: 0.79 at 5% of residual SS, 0.99 at 10%.

 **Within-group coherence (pairwise Spearman of cell orderings):**
A: 0.76-0.93, B: 0.64-0.95, C: 0.34-0.75, **D: 0.22-0.76**.
Group D does NOT cohere: in Qwen3, two D perturbations agree at rho=0.22, LESS than D agrees with A (0.33). "Type D sensitivity" is not a property of cells; individual D perturbations are. The group-level interaction is not separable from edit locus in this design.

 **Multiplicative structure (R21: first-order Taylor, deflated):**
Median angle sqrt(2d) is 0.04-0.28 rad (small-angle regime). To first order, d ~ gain(cell) x push(context), so log-additivity is expected from smoothness alone (Tukey F=60-490 confirms the first-order expansion, not a finding). The content is entirely in the 12-25% log-space residual, which is REAL deterministic structure (fp32 CPU, no noise term).

 **Defensible statement (post-R20):** On log scale, cell identity accounts for 13-46% and perturbation identity for 37-75% of cross-surface distance variance. The remaining 12-19% is deterministic cell × perturbation structure. In 4/5 models this is organized by perturbation group (cell × group share 0.26-0.40 vs 0.13 expected; group-label perm p <= 0.009). Phi is at chance. Inert appends (A, B) rank cells consistently (within-group rho 0.64-0.95); meaning-preserving rewrites (D) do not (0.22-0.76). Whether this is semantic type vs edit locus is not separable in the current design.

 **Gradient perm Z re-audit (R20 signal, resolved):** The gradient permutation test shuffles column labels WITHIN each row (np.random.shuffle per cell), NOT whole rows. This correctly randomizes perturbation-group assignment while preserving cell structure. The row-permutation defect does NOT apply. Gradient perm Z > 2 for all 7 tested models STANDS.

 **NESTED F + GROUP-LABEL PERM (all 8 models, log scale, 2026-09-19):**

| Model | Cell% | Pert% | Res% | CG share | F | perm p | A | B | C | D |
|---|---|---|---|---|---|---|---|---|---|---|

|--------------|-------|-------|------|----------|-------|---------|------|------|------|------|
| SmolLM2-135M | 44.2 | 44.1 | 11.7 | 0.270 | 2.47 | 0.009 | 0.92 | 0.81 | 0.76 | 0.71 |
| SmolLM2-360M | 26.6 | 48.7 | 24.8 | 0.303 | 2.89 | 0.0006 | 0.67 | 0.61 | 0.33 | 0.18 |
| SmolLM2-1.7B | 39.5 | 42.1 | 18.5 | 0.319 | 3.12 | 0.0002 | 0.86 | 0.88 | 0.75 | 0.44 |
| Qwen3-0.6B-I | 21.6 | 55.9 | 22.5 | 0.338 | 3.40 | 0.0002 | 0.79 | 0.75 | 0.46 | 0.17 |
| Qwen3-0.6B-B | — | — | — | — | — | pending | 0.91 | — | — | 0.39 |
| Qwen3-1.7B | 19.3 | 66.1 | 14.6 | 0.312 | 3.02 | 0.0002 | 0.78 | 0.84 | 0.59 | 0.22 |
| StableLM | 45.7 | 37.1 | 17.2 | 0.396 | 4.36 | 0.0002 | 0.93 | 0.95 | 0.51 | 0.57 |
| CodeGen | 12.6 | 74.9 | 12.4 | 0.255 | 2.29 | 0.0072 | 0.76 | 0.72 | 0.34 | 0.37 |
| Phi Q0 | 31.8 | 55.5 | 12.7 | 0.145 | 1.14 | 0.30 | 0.81 | 0.64 | 0.62 | 0.76 |

7/8 models: cell × group interaction significant (perm $p < 0.01$). Only Phi Q0 null.

**R21 CRITICAL QUALIFIER:** The interaction is present among inert contexts alone:

- AB vs C (D removed): $p \leq 0.004$ in 7/8 models. Rewrites NOT NEEDED for interaction.
- A vs B: null in 8/8 (negative control passing — two inert groups exchangeable).
- Comment-vs-statement within A+B: significant in 7/8 ($p=0.0006$-$0.07$).
- Replacing ABCD with comment/stmt/C/D lowers p in ALL 8 models (Phi: 0.30 → 0.002).

The declared groups are not the axes along which models organize the residual.
The interaction reflects CONTEXT FEATURES (locus, comment-vs-statement, token adjacency),
demonstrably including features that have nothing to do with meaning preservation.

**ATTENUATION RATIO (R21 central result):** observed A-D cross rho / sqrt(within-A × within-D)
= 0.79-1.01 across 8 models. A single common cell factor with column-specific noise
reproduces the A-D "gap" to within 0-20%. Inert appends predict each rewrite's cell ordering
as well as other rewrites do (8/8 models). "Not predictable from inert" WITHDRAWN;
"less reliable" is the supported phrase.

**Phi Q1 (admissible readout):** Cell%=52.7, Pert%=33.8, Res%=13.5, CG share=0.275,
perm $p=0.001$, A=0.90 B=0.85 C=0.76 D=0.71. SIGNIFICANT. 7/8 models significant under
Q0; Phi additionally under model-specific Q1 (post-hoc readout; Q1 inadmissible on Qwen3).
Phi Q0 null is a readout artifact.

Within-group coherence (A, B columns): pairwise Spearman of cell orderings 0.61-0.95.
Within-D coherence: 0.17-0.76 — GROUP D DOES NOT COHERE as a type.

**SCALE-DEPENDENT D-COHERENCE (new finding):**

SmolLM2 family: 135M D=0.71, 360M D=0.18, 1.7B D=0.44.
At smallest scale (52% acc): all D perturbations are interchangeable (model can't distinguish).
At medium scale (90% acc): D perturbations become HIGHLY DISTINCT (individual processing).
At largest scale (95% acc): partial reconsolidation.
Qwen3 (instruct): 0.6B D=0.17, 1.7B D=0.22 — consistently low.
**Qwen3-0.6B-Base: D=0.39 — 2.3x HIGHER than instruct.** Instruction tuning CREATES the
low D-coherence, not scale. Base model treats rewrites more interchangeably.
Implication: models develop perturbation-specific processing as they scale up. The distinction
between "equivalent rewrites" is a LEARNED property, not inherent. Instruction tuning
accelerates this differentiation (Base 0.39 → Instruct 0.17 at same scale).

**D-COHERENCE DECOMPOSITION (SmolLM2 scale ladder, zero-compute reanalysis):**

*R21 CORRECTIONS: all rhos carry CIs (bootstrap n=40, B=2000). No mechanism assertions.*
Mean D-coherence with CIs: 135M: 0.71 [0.55, 0.81], 360M: 0.18 [0.05, 0.31], 1.7B: 0.44 [0.27, 0.58].
Scale dependence of mean D-coherence is REAL (CIs don't overlap).

- **int_cast is the most isolated D context at 360M** (85% of cell bootstraps), uncorrelated (NOT anti-correlated — CIs include 0 and reach +0.15) with other D perts. Divergence driven by `-` and `%` cells: eta²(operator)=0.44 for int_cast residual. Effective n = 5 operator strata.
- **cond_true is the most isolated at 1.7B in SmolLM2 only** (97% of bootstraps). Does NOT replicate in any other model. Driven by `*1` and `//1` identity cells (eta²(operator)=0.64).
- **At 1.7B:** {int_cast, add_zero, zero_plus, parens} cluster (rho 0.56-0.78), {temp_var} and {cond_true} isolated. The first cluster has no arithmetic reading (parens is in it).
- **parens and int_cast** both delete the space token before the first operand. They are a top-3 D pair in 5/8 models. Tokenization confound is untested.
- **Cross-scale rank stability near zero (ALL groups, not D-specific):** Cell orderings reorganize with scale across all 24 columns: A mean rho=0.08, B=0.03, C=-0.30, D=0.11 (135M→360M). Row-mean fragility also near-zero cross-scale. Group C sign flip (-0.30) is the strangest number and is unexplained. "Which cells are sensitive" is a checkpoint property.
- **Cross-group coherence (A-D):** 0.80 (135M) -> 0.36 (360M) -> 0.58 (1.7B). At 135M the model doesn't distinguish groups; at 360M groups become very distinct; partial re-merge at 1.7B.
- **Phi's residual is NOT unorganized** — it is organized along comment-vs-statement (p=0.002) and C-vs-D (p=0.011), just not along ABCD. Its D columns' nearest neighbours are inert contexts. "No group-specific processing" WITHDRAWN.

□ **LOCUS CONFOUND ANALYSIS (all 8 models, zero-compute reanalysis):**

*Is the cell × group interaction driven by edit POSITION or semantic TYPE?*

Decompose the A-D coherence drop into locus effect (A-B minus A-C) and type effect (A-C minus A-D).

| Model | Locus | Type | Total | Dominant |
|---|---|---|---|---|
| SmolLM2-135M | 0.065 | -0.004| 0.061 | Neither |
| SmolLM2-360M | 0.437 | -0.146| 0.291 | LOCUS |
| SmolLM2-1.7B | 0.190 | 0.089 | 0.278 | Locus |
| Qwen3-0.6B | 0.265 | 0.202 | 0.467 | Mixed |
| Qwen3-1.7B | 0.200 | 0.279 | 0.479 | **TYPE** |
| StableLM-1.6B| 0.349 | -0.041| 0.309 | LOCUS |
| CodeGen-350M | 0.377 | -0.090| 0.287 | LOCUS |
| Phi-1.5-Q0 | 0.030 | -0.042| -0.013| Neither |

**5/8 models have negative type effect:** D rewrites are MORE coherent with A (post-assignment appends) than C (pre-assignment insertions) are. The cell × group interaction is primarily driven by WHERE the edit goes, not WHAT it does. Only Qwen3-1.7B shows genuine semantic type dominance (type 0.28 > locus 0.20).

**Mean distance pattern:**

SmolLM2/StableLM/CodeGen: A ~= B > D > C (before-assignment is LEAST disruptive).

Qwen3: D > C ~= A ~= B (rewrites are MOST disruptive — architecture-specific).

**B/C matched-pair test (same operation, different position):**

Matched-pair rho (e.g., a_comment vs c_comment_before) vs unmatched A-C cross rho: difference < 0.06 for 7/8 models. Matching by operation provides NO additional predictive power. Cell ordering is determined by position, not by what specific inert operation is performed.

**CONCLUSION:** The 7/8 cell × group interaction is REAL but primarily reflects edit POSITION, not the semantic content of the edit. This is TOTAL for A/B/C groups.

**What IS NOT confounded (genuine type effects):**

- Within-D structure (arithmetic vs control-flow clusters) — all D perts at the same locus
- Scale-dependent D-coherence — position is constant across scale, so it can't explain changes
- Qwen3-1.7B type effect (0.28 > locus 0.20) — small but genuine
- D-coherence < C-coherence in 5/8 models — rewrites produce more heterogeneous cell orderings
than before-assignment insertions, independent of cross-group position confound
- Per-D-pert vs A-mean cell ordering: some D perts DIVERGE from the general cell-fragility
hierarchy. zero_plus has r=-0.07 (ANTI-correlated) at Qwen3-0.6B and r=0.10 at SmolLM2-360M.
These rewrites probe pathways ORTHOGONAL to append-based sensitivity. The interaction is genuine.

 **WITHIN-D DEEP ANALYSIS (all 8 models, zero-compute):**
*Which D perturbations are most disruptive? Is there a universal ordering?*
- **Kendall W = 0.152:** NO universal D-perturbation ordering. Which rewrite is most disruptive
is completely model-dependent.
- **Architecture preserves ranking:** Qwen3-0.6B vs 1.7B r=0.943 (p=0.005). Same architecture
at different scales ranks rewrites the same way: temp_var > cond_true > zero_plus > add_zero.
- **Scale CAN reverse ranking:** SmolLM2-135M vs 1.7B r=-0.771. The disruption hierarchy
inverts with scale (parens most disruptive at 135M; add_zero most at 1.7B).
- **Structural complexity does NOT predict disruption** (all Spearman rho NS). Adding more tokens
doesn't make a rewrite more disruptive — the model's processing matters, not edit size.
- **Cell fragility generalizes (multiplicative):** D-mean vs A-mean cell-level rho = 0.56-0.98.
Cells that are sensitive to appends are also sensitive to rewrites. BUT:
- **Some D perts are ORTHOGONAL to cell fragility:** Per-D-pert vs A-mean ranges from -0.07
(zero_plus, Qwen3-0.6B) to 0.93 (cond_true, SmolLM2-135M). Perturbations that diverge
most from A-ordering: zero_plus (r=0.10 at 360M), cond_true (r=0.11 at 360M), int_cast
(r=0.22 at Qwen3-0.6B). These rewrites activate cell-specific pathways independent of
general model sensitivity — they're the source of the genuine interaction term.

 **RESIDUAL DIRECTION STRUCTURE TEST (permutation-validated, 4 models):**
Within-D log-additive residual: pairwise column correlations range -0.55 to +0.57.
The mean (~-0.18) is explained by the row-sum-to-zero constraint (expected = -0.20).
But the SPREAD of correlations exceeds the constraint-induced expectation:

| Model | Obs SD | Null SD | Z | perm p | Verdict |
|---|---|---|---|---|---|
| SmolLM2-360M | 0.338 | 0.167 | 5.82 | 0.0005 | SIGNIFICANT|
| SmolLM2-1.7B | 0.280 | 0.157 | 3.85 | 0.001 | SIGNIFICANT|
| Qwen3-0.6B | 0.166 | 0.154 | 0.38 | 0.33 | Null |
| Qwen3-1.7B | 0.247 | 0.157 | 2.91 | 0.007 | SIGNIFICANT|

**In 3/4 models, D perturbations push logits in genuinely DIFFERENT DIRECTIONS, not just
different amounts.** This is the cleanest evidence for perturbation-specific processing:
it's within-D (same code position), in the residual (controls for multiplicative cell
fragility x perturbation magnitude), and permutation-validated against the constraint null.
Specific antagonistic pairs at SmolLM2-360M: int_cast vs add_zero (-0.55), parens vs
zero_plus (-0.53). The {parens, int_cast} cluster opposes the {zero_plus, cond_true} cluster.

 **DIRECTION STRUCTURE CORRELATES WITH TRANSFER (algebraically expected, NOT a mechanism):**
**R21 TAUTOLOGY WARNING:** rho_raw(i,j) is approximately a monotone function of r_resid(i,j)
when var(cell) dominates: both measure how much two perturbation columns share cell-specific
structure. The meta-r values (0.51-0.83) are algebraically expected from the decomposition,

not an independent finding. Values below 1.0 reflect Spearman-vs-Pearson mismatch and variation in per-perturbation residual variance. This is a consistency check, not a mechanism.

Meta-correlation between residual pairwise rho and raw pairwise within-D transfer:

| Model | Meta r | Meta p |
|---|---|---|
| Qwen3-0.6B | 0.829 | 0.0001 |
| SmolLM2-360M | 0.814 | 0.0002 |
| Qwen3-1.7B | 0.711 | 0.003 |
| CodeGen-350M | 0.536 | 0.040 |
| SmolLM2-1.7B | 0.514 | 0.050 |
| StableLM-1.6B| 0.332 | 0.227 |

**In 5/6 models, the residual direction correlates with pairwise transfer.** Pairs with anti-correlated residuals have low raw transfer rho. This is algebraically expected from the log-additive decomposition (see R21 tautology note above), NOT an independent mechanism. The observation is consistent with the decomposition but carries no additional content.

Consistently worst-transferring D pairs (cross-model mean rho):

- int_cast-cond_true: 0.146 (arithmetic vs control-flow divide)
- zero_plus-cond_true: 0.208
- int_cast-zero_plus: 0.243

Best-transferring: parens-int_cast (0.552), parens-add_zero (0.428).

Cell-fragility correlation: zero_plus consistently lowest (0.35-0.67). These are perturbations that LEAST follow the general sensitivity pattern — they activate perturbation-specific processing pathways independent of overall cell fragility.

**R21 caveat:** inert appends predict each rewrite's cell ordering as well as other rewrites do (leave-one-D-out, 8/8 models). The attenuation ratio (0.79-1.01) shows a single common cell factor reproduces the A-D gap. The direction divergence finding (above) is real in the RESIDUAL (3/4 perm-validated), but the residual is 12-25% of total variance. The practical question is whether that 12-25% matters for fine-tuning/alignment robustness.

Tokenization confound: parens and int_cast both delete the space token before the operand; they are a top-3 D pair in 5/8 models. Space-restoration test needed to distinguish tokenization artifact from semantic processing.

**Surviving implication:** Sensitivity is predominantly about cell fragility × context magnitude (multiplicative). The residual direction structure is real but small, and its organization by surface features (locus, comment-vs-statement, token adjacency) rather than semantic type is the currently supported interpretation.

- **DIRECTION STRUCTURE IS UNIVERSAL ACROSS GROUPS (not D-specific):**

Tested direction divergence (residual pairwise-rho SD vs row-permutation null) for each group:

| Model | A Z | B Z | C Z | D Z |
|---|---|---|---|---|
| SmolLM2-360M | 13.80 | 6.92 | 2.17 | 5.82 |
| SmolLM2-1.7B | 9.45 | 4.15 | 1.50 | 3.85 |
| Qwen3-1.7B | 8.26 | 5.58 | 3.59 | 2.91 |

**Groups A and B show STRONGER direction divergence than D.** Even different inert appends push logits in genuinely different directions. Direction divergence is a general property of how contexts modulate header sensitivity, not a signature of meaning-preserving rewrites.

Group C (before-assignment insertions) shows weakest structure, consistent with the locus confound: positional adjacency to the header is the primary axis, not semantic content. This supports R21's reframe: residual structure tracks surface features (locus, comment-vs-statement, token adjacency), not whether the context is a meaning-preserving rewrite.

 **CROSS-MODEL DIRECTION PREDICTION FAILS (underpowered negative result):**
**R21 POWER NOTE:** All comparisons at n=15 perturbation pairs. Critical rho ~0.52 at alpha=0.05. Leave-one-out: cross-mean 0.01-0.26, all NS. Self-prediction: 0.33-0.83 (partly NS: CodeGen 0.33). Within-family: SmolLM2-360M vs 1.7B = -0.37 (NS), Qwen3-0.6B vs 1.7B = -0.30 (NS). At n=15, we cannot distinguish "direction structure is model-specific" from "insufficient power." The "double non-transfer" framing is unsupported: self-prediction is partly NS, and cross-prediction NS results could reflect low power rather than genuine model specificity.

 **CROSS-MODEL FRAGILITY NOT DETECTABLY CORRELATED (zero-cost, 9 model-readouts, underpowered):**
**R21 POWER NOTE:** At n=40, power to detect rho=0.3 is ~50%. 36 pairwise comparisons with no multiple-testing correction; expect 1.8 false positives at alpha=0.05. "Completely model-specific" is not testable at this sample size. Two significant negative pairs are reported below.
Per-cell fragility rank-correlated between all model pairs:
- **Within-family rho near ZERO:** Qwen3-0.6B vs 1.7B: rho=0.032 (p=0.84). SmolLM2-135M vs 360M: -0.123 (p=0.45). SmolLM2-360M vs 1.7B: 0.065 (p=0.69). All NS.
- **Cross-family near ZERO:** Qwen3-1.7B vs SmolLM2-1.7B: 0.125 (p=0.44).
- **Two significant NEGATIVE pairs:** Qwen3-0.6B vs SmolLM2-1.7B: -0.494. SmolLM2-1.7B vs Phi-Q0: -0.491. Cells most fragile in one are LEAST in the other.
- **Consensus std (4.5) = random (4.7).** No cell is universally fragile or robust.
- **Extreme reorganization:** Cell `1**5` rank 0 in Qwen3-1.7B, rank 35 in Qwen3-0.6B.
**R21-corrected implication:** At n=40, no consistent cross-model fragility pattern is detectable (power ~50% at rho=0.3). The claim "vulnerability location is model-specific" is a power limitation, not a demonstrated biological fact. Needs n >= 200 diverse cells to be testable.

 **COMPLETE SCALE LADDER RESIDUAL ANALYSIS (2026-09-19):**
| Model | Gap | Resid gap | Resid CI | PC1% | Gates |
|---|---|---|---|---|---|
| SmolLM2-135M | 0.121 | 0.105 | [-0.015, 0.251] | 69.6% | FAIL (CI incl 0) |
| SmolLM2-360M | 0.318 | 0.384 | [0.205, 0.480] | 90.5% | ALL PASS |
| SmolLM2-1.7B | 0.281 | 0.310 | [0.091, 0.533] | 78.2% | ALL PASS |
| Qwen3-0.6B | 0.489 | 0.309 | [0.115, 0.487] | 53.1% | ALL PASS |
| Qwen3-1.7B | 0.452 | 0.230 | [0.077, 0.430] | 51.0% | ALL PASS |

**SmolLM2-360M residual (0.384) EXCEEDS raw gap (0.318).**
**R21 SUPPRESSOR WARNING:** This occurs at the highest PC1 share (90.5%). When partialling out 90.5% of variance, the residual gap computed on the remaining 9.5% can be inflated by suppressor artifacts (PC1 shares variance with both signal and noise). SmolLM2-135M (PC1=69.6%) contradicts the suppression story: lower PC1 but fails (CI incl 0). The pattern (residual > raw only at highest PC1) is consistent with a suppressor artifact, not evidence that fragility masks type-specificity. SmolLM2 raw gap CIs overlap (360M [0.207, 0.431] vs 1.7B [0.197, 0.385]); "non-monotonic scaling" is not significant at n=3 scale points.

 **D-GROUP INTERNAL STRUCTURE IS COMPLETELY MODEL-SPECIFIC (8 models, 2026-09-19):**
Within-D rho (mean of 15 pairs) ranges from 0.169 (Qwen3-0.6B) to 0.712 (SmolLM2-135M).

Cross-model consistency of D-pair rho vectors: 0/28 model pairs significant after correction.
Median cross-model rho = +0.03, range = [-0.46, +0.52]. D-group internal structure is random
across models. No D-perturbation is consistently "most anomalous":

| Model | Most anomalous D-pert | Mean rho with others |
|---|---|---|
| Qwen3-1.7B | temp_var | -0.005 |
| SmolLM2-1.7B | cond_true | +0.232 |
| StableLM-2-1.6B | zero_plus | +0.411 |
| CodeGen-350M | cond_true | +0.197 |
| SmolLM2-360M | int_cast | -0.002 |
| Qwen3-0.6B | int_cast | +0.086 |
| Phi-1.5-Q1 | add_zero | +0.674 (ALL cohere) |
| SmolLM2-135M | zero_plus | +0.662 (ALL cohere) |

D-coherence anticorrelates with model capability: 135M and Phi-Q1 (high coherence) treat
all rewrites similarly; Qwen3 and SmolLM2-360M (low coherence) differentiate rewrites.
**D-coherence does NOT predict residual gap** (Spearman rho=+0.05, p=0.91, n=8).
**Raw gap does NOT predict residual gap** (rho=-0.11, p=0.80). Fragility partialling
completely reshuffles the model ordering.
**INSTRUCT EFFECT ON D-COHERENCE (Qwen3-0.6B, same tokenizer):**
Base within-D rho = 0.394 vs Instruct 0.169 (2.3x). Instruction tuning makes D
perturbations LESS interchangeable. parens<->int_cast coupling: Base 0.729 vs Instruct
0.183. This is NOT tokenization (same tokenizer) — instruction tuning reorganizes how
the model processes meaning-preserving rewrites.
**Combined with cross-model fragility (above):** both WHICH cells are fragile and HOW
rewrites interact with cells are not detectably correlated across models (all underpowered
at n=40). The sensitivity fingerprint appears unique to each model but confirmation
requires n >= 200 cells (see R21 section 3.3).

□ **Next steps (post-R21 design):**

R21 specifies: NO NEW CLAIMS until a properly designed next experiment exists.
(1) **Operator-balanced cells:** n >= 60, no identity expressions (`x*1`, `x//1`, `1**5`),
balanced operator strata (12+ per class). Current effective n = 5 operator strata.
(2) **Space-token restoration:** `x = ( e )` and `x = int( e )` (spaced variants, ~10 min/model).
Tests whether parens/int_cast coupling is tokenization artifact.
(3) **Before-locus rewrite:** `_f = lambda: e; x = _f()` — rewrite placed BEFORE assignment.
Should behave like C if locus is the mechanism.
(4) **Comment-vs-statement within D:** `x = e # ok` vs `x = e; pass`. If this separates D,
"type" has no residual role.
(5) **k >= 3 surface instances** per context for proper error term.
(6) **Locus-crossed design** for A/B/C confound separation.
(7) **Qwen3-0.6B-Base** ~~to resolve instruct confound~~ — **RESOLVED (2026-09-19).** Gap 0.087
vs instruct 0.489 (like-for-like 1.5x; R23 corrected from 5.6x definition artifact).
(8) **Base model for other families** — SmolLM2, StableLM have no instruct variant tested.
Only Qwen3 has the Base/Instruct comparison. Need ≥1 more family to generalize.
Estimated cost: one CPU afternoon per model at 60+ cells.

□ **BALANCED CELL V3 RESULTS (69 cells, no identity, operator-balanced, 2026-09-19):**

| Model | Gap | CI 95% | Perm Z | Residual Gap | DD | AD |
|---|---|---|---|---|---|---|
| Qwen3-1.7B | **0.500** | [0.411, 0.588] | 8.7 | 0.462 (92%) | 0.337 | 0.337 |
| SmolLM2-1.7B | **0.275** | [0.202, 0.362] | 4.3 | 0.389 (141%) | 0.531 | 0.669 |

DD < AD in both. Gap survives on balanced cells in both models. SmolLM2 residual HIGHER than raw (operator strata absorb some gap; partialling increases A-D difference).
Qwen3 residual 92% of raw (operator effect is small). SmolLM2 eta²(operator)=0.687.
**R21 precondition MET.** Cross-model claims now admissible on balanced cells.
**R21 falsifiable claim:** each context column = common cell factor + column-specific residual; the residual is organized by surface features (locus, comment-vs-statement, token adjacency) and NOT by whether the context is a meaning-preserving rewrite.

**MEANING-CHANGE TRANSFER TEST (2 models, Group E, fp32 CPU, 2026-09-18; R24-CORRECTED):**
Cell-level Spearman correlation between perturbation-group mean sensitivity profiles.
**R24 CORRECTIONS (16/40 cells are identity expressions — dominant confound):**
On non-identity cells only (n=24):

| Transfer | Qwen3-1.7B | SmolLM2-1.7B |
|---|---|---|
| Inert (A+B) → E | 0.066 (NS) | 0.143 (NS) |
| D (rewrites) → E | **0.455** (p=0.026) | 0.393 (p=0.057) |
| add_zero+cond_true → E | **0.708** (p<0.001) | **0.438** (p=0.032) |
| Other 4 D members → E | 0.123 (NS) | 0.277 (NS) |

D→E > Inert→E holds (0.46/0.39 vs 0.07/0.14) but is driven by 2 of 6 D members (add_zero, cond_true) that share token-prefix form with E members (e_plus_one, e_minus_one).
**RETRACTED:** SmolLM2 Inert→E significance (identity-cell artifact).
**RETRACTED:** "Whether inert predicts E depends on model" (Fisher z=1.29, p=0.195, NS).
**DOWNGRADED:** "Additive transfers, multiplicative doesn't" (confounded with prefix form).
**WITHDRAWN:** "D captures proximity to genuine behavioral vulnerability" (no behavioral quantity measured; Qwen3 full-logit cosine cell-profile doesn't correlate with 11-bin at all).
**TOKEN-PREFIX NULL:** d_add_zero → e_plus_one = 0.861 (SmolLM2): differ by one token.
Prefix-breaking D members (temp_var, parens) → E ≈ 0 on non-identity cells.
E-group partial coherence after removing form twins ≈ 0.
**STRONGEST VERSION (R24):** Cross-surface logit-geometry sensitivity transfers between perturbations sharing a token prefix with the cell, regardless of meaning preservation.
No evidence yet of a meaning-change factor beyond shared token form.

**PREFIX-FORM CROSSOVER TEST (Qwen3-1.7B, 2x2 design, fp32 CPU, 2026-09-19):**
2x2: D members (add_zero=`e+0`, zero_plus=`0+e`) x E members (plus_one=`e+1`, one_plus=`1+e`).
Non-identity cells (n=24):

| D \ E | plus_one (e+1) | one_plus (1+e) |
|---|---|---|
| add_zero (e+0) | **0.634** | -0.301 |
| zero_plus (0+e) | 0.428 | 0.063 |

Diagonal mean: 0.349, off-diagonal mean: 0.063. E-E rho: -0.143.
**R25 REANALYSIS: Column main effect, not diagonal (see R25 below).**
zero_plus→plus_one (0.428, diff prefix) > zero_plus→one_plus (0.063, same prefix) — breaks clean prefix prediction. Operator strata reverse Qwen3 diagonal within-stratum.

**SmolLM2 replication (n=24):** add_zero→plus_one **0.676**, add_zero→one_plus -0.405,
zero_plus→plus_one 0.390, zero_plus→one_plus -0.159. E-E rho: **-0.470 (p=0.021, SIG)**.
All four signs replicate Qwen3. E-E anti-correlation significant in SmolLM2.
**VARIANCE ANALYSIS (zero-cost):** add_zero has 3.5-4.3x more cross-cell variance than
zero_plus. Full D×E table: d_temp_var REVERSES the column effect in both models.
Mean D → plus_one: +0.311 (p=0.139, NS). Mean D → one_plus: -0.277 (p=0.191, NS).
**NEITHER PREFIX NOR GRADIENT HYPOTHESIS SURVIVES** aggregation over all D members.
**FULL-LOGIT-ONLY FINDINGS (RETRACTED AS GENERAL CLAIMS):**
(1) E-E anti-correlation (full-logit only: -0.143 Qwen3, -0.470 SmolLM2). REVERSED on 11-bin.
(2) add_zero→one_plus anti-transfer (-0.301/-0.405): full-logit only. On 11-bin: +0.531.
(3) Member-specificity: full-logit only. On 11-bin, all four entries positive and significant.

□ **11-BIN CROSSOVER REANALYSIS (Qwen3, 160 fwd passes, 2026-09-19):**

| Cell | Full-logit | 11-bin |
|---|---|---|
| add_zero→plus_one | +0.634 | +0.610 |
| add_zero→one_plus | -0.301 | **+0.531** |
| zero_plus→plus_one | +0.428 | **+0.710** |
| zero_plus→one_plus | +0.063 | **+0.423** |
| **E-E rho** | -0.143 | **+0.758 (p<0.001)** |

Diag mean: FL 0.349, 11-bin 0.517. Off-diag mean: FL 0.063, 11-bin 0.620.
**TOKEN-PREFIX NULL REFUTED on answer distribution.** All additive perturbations transfer
regardless of operand position on 11-bin. E-E flips from anti-correlated to r=+0.76.
Off-diagonal > diagonal on 11-bin: gradient hypothesis wins over prefix hypothesis.
**REFRAMING:** The gap measures D-DIVERSITY (how differently each D member modulates
a common cell-sensitivity factor), not D-DISCONNECTION from E. D→E transfer is REAL
on 11-bin (Qwen3).

□ **11-BIN CROSSOVER REPLICATION (SmolLM2, 160 fwd passes, 2026-09-19):**

| Cell | Full-logit | 11-bin |
|---|---|---|
| add_zero→plus_one | +0.676 | **+0.564** |
| add_zero→one_plus | -0.405 | +0.089 (NS) |
| zero_plus→plus_one | +0.390 | +0.170 (NS) |
| zero_plus→one_plus | -0.159 | +0.129 (NS) |
| **E-E rho** | -0.470 (p=0.021) | +0.124 (NS, p=0.563) |

Diag mean: FL 0.258, 11-bin 0.347. Off-diag mean: FL -0.007, 11-bin 0.130.
**PARTIAL REPLICATION:**
(a) Anti-correlation artifact: CONFIRMED. E-E flips sign in both models (SmolLM2: -0.47→+0.12).
(b) Broad positive transfer: QWEN3-SPECIFIC. SmolLM2 has 1/4 entries significant on 11-bin
vs Qwen3's 4/4. Only add_zero→plus_one survives in both models.
(c) add_zero is the "privileged" D member: highest variance (3.5-4.3x), only D member
whose cross-perturbation transfer survives both readouts in both models.
(d) Reframing qualified: D-diversity is real, but D→E transfer strength on 11-bin
is model-dependent. The gap measures D-diversity; whether that diversity implies
D→E transfer on answer distributions depends on the model.

□ **FABLE R25 ADVERSARIAL REVIEW (2026-09-19) — MAJOR CORRECTIONS:**

The 2×2 is a COLUMN main effect, not a diagonal/prefix effect.

| Contrast (n=24) | Qwen3 | SmolLM2 |
|---|---|---|
| Column (plus_one − one_plus) | **+0.65** [+0.21, +1.01] | **+0.82** [+0.19, +1.28] |
| Row (add_zero − zero_plus) | −0.08 | +0.02 |
| Interaction (diag − offdiag) | +0.29 [−0.04, +0.61], p=0.085 | +0.27 [−0.04, +0.60], p=0.052 |

Only the column CI excludes zero. Diagonal interaction NS in both models.

**one_plus is a column anomaly:** anti-correlates with 17/18 inerts in Qwen3 (mean rho -0.44).

`1 + e` is a GARDEN PATH for `* // %` cells (precedence override). Not equivalent to `e + 1`.

**Operator strata reverse Qwen3 diagonal:** within-stratum ad→plu = −0.23. The 0.634 is between-operator structure on an unbalanced set. SmolLM2 ad→plu survives within-operator (+0.52) but interaction collapses to 0.04.

**RETRACTIONS (R25):**

- "Prefix form is partial mediator" → DOWNGRADE to "one append-twin transfers"
- "E-E independence" → RETRACT (Qwen3 CI spans zero; SmolLM2 significantly negative)
- "Meaning change determines which cells affected" → WITHDRAW (no meaning-preserving late twin measured; no 11-bin E readout on old cells)
- "Token-prefix sharing" → NARROW to late-edit locality

**MOST HONEST READING (R25):** Edit locality relative to `e` plus precedence artifact in `1 + e`. Append-after-e edits (add_zero, plus_one, minus_one, cond_true, times_two) cohere at rho 0.43-0.66. Prepend/wrap edits do not. Meaning change has NO demonstrated role — no meaning-preserving late twin (e-0, e*1) was ever measured.

**LATE-TWIN DISAMBIGUATION (Qwen3, balanced v3, 828 fwd passes, 2026-09-19):**

6 append-after-e perts: D (e+0, e-0) vs E (e+1, e-1, e+2, e+3). Both readouts.

| Readout | D-D mean | D-E mean | E-E mean | D-D minus D-E |
|---|---|---|---|---|
| Full-logit | **+0.658** | +0.424 | +0.405 | **+0.234** |
| 11-bin | +0.591 | +0.644 | **+0.781** | **-0.053** |

**MEANING IS DEAD ON 11-BIN.** On the answer distribution, D-D < D-E < E-E. Meaning-changing perturbations are MORE internally coherent than meaning-preserving ones. e+0 correlates MORE with E members (0.73-0.83 on 11-bin) than with e-0 (0.59). All late-edit perts load on a common "surface sensitivity" factor. Meaning changes AMPLIFY this factor because answer shifts increase prediction uncertainty (E-E > D-E > D-D on 11-bin).

Full-logit shows D-D > D-E because formatting geometry encodes operator identity (+/-) separate from meaning. This is the known readout disconnect.

**Full-logit bootstrap CI on D-D minus D-E: [+0.082, +0.382]** (excludes zero, N=2000 resamples). Meaning distinction is real on formatting geometry. 11-bin bootstrap pending.

**SmolLM2 REPLICATION (828 fwd passes, 2026-09-19):**

| | Qwen3 FL | Qwen3 11b | SmolLM2 FL | SmolLM2 11b |
|---|---|---|---|---|
| D-D | +0.658 | +0.591 | +0.704 | +0.365 |
| D-E | +0.424 | +0.644 | +0.468 | +0.349 |
| E-E | +0.405 | +0.781 | +0.541 | +0.415 |
| D-D - D-E | +0.234 | -0.053 | +0.236 | +0.015 |
| FL CI | [+0.082, +0.382] | — | [+0.106, +0.357] | — |

| 11b CI | pending | — | [-0.171, +0.200] | — |

**3-MODEL REPLICATION (Qwen3, SmolLM2, StableLM-2, 2026-09-19):**

| Model | FL D-D-DE | FL CI | 11b D-D-DE | 11b CI |
|---|---|---|---|---|
| Qwen3-1.7B | +0.234 | [+0.082,+0.382]* | -0.053 | pending |
| SmolLM2-1.7B | +0.236 | [+0.106,+0.357]* | +0.015 | [-0.171,+0.200] |
| StableLM-2-1.6B | **-0.017** | [-0.170,+0.129] | -0.044 | [-0.201,+0.122] |

*CI excludes zero. StableLM shows edit locality on BOTH readouts.

**11-bin: 3/3 models show no meaning effect (CI spans zero where measured).**

**Full-logit: 2/3 models show meaning matters; StableLM does not.** The FL meaning distinction is model-specific, likely reflecting operator token (+/-) encoding that varies by architecture. StableLM doesn't encode this distinction in formatting geometry.

**ADVERSARIAL REVIEW (self, 2026-09-19):** Strongest attack: D has only 1 D-D pair. Correct claim: "fail to detect meaning effect" (null), not "meaning is dead" (positive).

**EXPANDED-D LATE-TWIN (3 models, 2026-09-19):** 4 D perts (e+0, e-0, e*1, e**1) + 6 E perts (e+1, e-1, e+2, e+3, e*2, e**2) = 6 D-D, 24 D-E, 15 E-E pairs.

| Model | FL D-D-DE | FL CI | 11b D-D-DE | 11b CI |
|---|---|---|---|---|
| Qwen3-1.7B | +0.048 | [-0.050, +0.148] | **-0.111** | **[-0.186, -0.033]*** |
| SmolLM2-1.7B | +0.180 | [+0.074, +0.285]* | +0.085 | [-0.017, +0.189] |
| StableLM-2-1.6B | +0.095 | [+0.009, +0.194]* | +0.062 | [-0.010, +0.140] |
| SmolLM2-360M | -0.031 | [-0.076, +0.009] | -0.035 | [-0.097, +0.024] |

*CI excludes zero. **Qwen3 11-bin excludes zero NEGATIVE (REVERSED). 360M both REVERSED.**

**11-bin: 0/4 positive meaning. 2/4 reversed (Qwen3, 360M).**

**FL: 1/4 clear (SmolLM2-1.7B), 1/4 marginal (StableLM), 2/4 not detected (Qwen3, 360M).**

Qwen3 FL REVERSAL from original late-twin: original CI [+0.082, +0.382], now [-0.050, +0.148]. Adding e*1/e**1 to D broke additive-family coherence that drove original D-D > D-E.

**OPERATOR FAMILY DECOMPOSITION (3 models, zero-cost, 2026-09-19):**

Within same operator family, meaning on 11-bin = +0.002 (Qwen3), +0.008 (SmolLM2), -0.090 (StableLM). ALL three show ZERO within-family meaning effect on answer distribution. Operator-family effect is +0.119 to +0.422 in SmolLM2/Qwen3 (real structure), near-zero in StableLM (+0.026). The FL "meaning matters" in SmolLM2 is partly family clustering. Same-family D-E can exceed same-family D-D (e+0~e+1 > e+0~e-0 in SmolLM2).

**CROSS-POSITION ANALYSIS (zero-cost, full-logit, 2026-09-19):**

A-A > A-C in both models (CI excludes zero). After-perts cohere within position. A-D ≈ C-D in both: rewrites equally low from both positions.

**ADVERSARIAL REVIEW OF EXPANDED-D (Fable, 2026-09-20):** CRITICAL FINDING — expanded-D experiment is confounded. D={+0,-0,*1,**1} spans 3 operator families. D-D pairs are predominantly cross-family (penalized by family heterogeneity). D-E pairs include same-family matches (boosted by family coherence). SmolLM2-360M confirms: both surfaces reversed (D-E > D-D). Ratings: meaning-dead QUALIFIED (failure-to-reject not evidence-for-null), FL=clustering SOLID, family>meaning QUALIFIED (true by construction), expanded-D-fix FRAGILE (introduced worse confound). **FIX: same-family D expansion (additive-only, eliminates confound). Pending.**

**REFRAMING (POST-ANSWER-IDENTITY-CONFOUND, 2026-09-20):** The gap measures POSITIONAL

non-transfer and OPERATOR-FAMILY structure. Meaning preservation contributes NOTHING
beyond answer identity.
**ISOMORPHIC SAME-FAMILY D (4 models) — RETRACTED due to answer identity confound:**
D={+0,-0,+(0),-(0)}, E={+1,-1,+(1),-(1)}. The DD-DE comparison is confounded:
D perts ALL produce the same answer (x), E perts produce x+1 or x-1. Answer identity
is perfectly collinear with the D/E label in DD-DE pairs. The correct isomorphic
comparison is DD-EE, which shows no effect (SmolLM2-1.7B: FL p=0.071, 11b p=0.157).
**ANSWER IDENTITY CONFOUND TEST (all 4 models × 2 surfaces):**
Cleanest test: same-answer pairs (D-D vs E-E-same-sign). If meaning matters beyond
answer identity, D-D > E-E-same-sign. Result: D-D <= E-E-same-sign in ALL 8 tests.
| Model | Surface | D-D | EE-same-sign | Diff |
|---|---|---|---|---|
| SmolLM2-1.7B | FL | +0.782 | +0.770 | +0.012 (null) |
| SmolLM2-1.7B | 11-bin | +0.489 | +0.538 | -0.048 (reverse) |
| Qwen3-1.7B | FL | +0.563 | +0.588 | -0.025 (null) |
| Qwen3-1.7B | 11-bin | +0.562 | +0.765 | -0.204 (reverse) |
**MEANING: SMALL, MODEL-DEPENDENT (R29 correction of 62h retraction).**
The original "D-D <= E-E-same-sign in ALL 8 tests" was biased: D-D averaged 6 pairs
(4 cross-sign), E-E-same-sign averaged 2 (all same-sign). Corrected sign-and-form-matched
comparison (DDsame vs EEsame, n=2 pairs per side): SmolLM2-1.7B +0.105 [0.025, 0.199] FL,
+0.231 [0.116, 0.350] 11-bin (EXCLUDES 0). Qwen3-1.7B 11-bin: -0.132 (REVERSED). StableLM
FL: +0.058 [0.001, 0.130]. Score: 4/8 D>E excl 0, 1/8 reversed, 3/8 null. Meaning is NOT
zero — it is small, model-dependent, and fragile at n=2 pairs.
Dominant factor is SIGN MATCHING (+0.19); meaning vs answer identity is non-identifiable
in this arithmetic design (62i regression parametrization was a choice, not a finding).
Factor ordering: position >> sign >> (form, answer, meaning non-identifiable below sign).
R30b (corrected post-Fable review): op-stratified in-expression edits (J) are INTERMEDIATE
(J-J=0.53-0.59 vs I-I=0.87, D-D=0.29), not D-like as initially pooled (0.413). Pooled
statistic was dominated by `//`-comment artifact and between-operator block structure.
Whitespace inside expression is inert; single-operand parenthesisation partially non-inert.
"Rarity fits the ordering" WITHDRAWN — was a pooling artifact; op-stratified loadings are
flat (0.53-0.60) across all AST-preserving in-expression edits despite 3x surprisal range.
Three-level plateau: outside-expression (0.77-0.85), AST-preserving in-expression (0.53-0.60),
computation-changing (-0.01 to 0.57). All cell-ranking rhos conditional on `# Output: ` readout.
 **R27 2×2 D-RELIABILITY DIAGNOSTIC (Qwen3-0.6B + SmolLM2-360M, 2026-09-20):**
D unreliability is STRUCTURED — 2-model universal finding. 24 perts in 4 groups:
A (inert), D (adjacent semantic ops), V (lexical variants of D), O (own-line versions of D).
| Metric | Qwen3-0.6B | SmolLM2-360M |
|---|---|---|
| A-A | +0.696 | +0.780 |
| O-O | +0.660 | +0.609 |
| D-D | +0.392 | +0.412 |
| Within-op D↔V | +0.632 | +0.912 |
| Cross-op | +0.366 | +0.481 |
**Universal (2 models):** (1) D unreliability is structured — 5-6/6 operations reliably measure

different cell properties (within-op >> cross-op). (2) O-O >> D-D in both models:
detaching semantic ops from the expression increases reliability.
**Model-specific:** (1) In Qwen3, O ≈ A (A-O=0.552, O-O≈A-A); in 360M, O is BETWEEN A and D
(A-O=0.409 < A-D=0.536). (2) temp_var: anti-correlated in Qwen3 (-0.346), structured in
360M (+0.821).
**R29 INLINE-INERT EXPERIMENT (2 models, 2026-09-20): WHICH-LINE EFFECT IS ZERO.**
Added group I (in-line inerts: comment, semicolon, tab, extra space).
DESIGN FLAW: i_trail_space = a_whitespace (bit-identical duplicate). Corrected numbers:
| Metric | Qwen3-0.6B | SmolLM2-360M |
|---|---|---|
| A-A (corrected) | +0.826 | +0.746 |
| I-I (corrected) | +0.878 | +0.789 |
| D-D | +0.392 | +0.412 |
| I-I − A-A | +0.052 | +0.044 |
| I-I − D-D | +0.486 | +0.377 |
**R30b IN-EXPRESSION INERTS — CORRECTED post-Fable review (Qwen3-0.6B, 2026-09-20):**
In-expression edits (J group) pooled J-J = +0.413, but Fable review found 3 SERIOUS defects:
(1) `//`-comment artifact: j_space_before_op on 15 `//` cells creates `x = 3 // 4` read
as C-style comment by bare surface (10x distance inflation, dominates pooled rho).
(2) j_spaces_both is pseudo-replicate of j_space_before_op (rho 0.957).
(3) j_unary_first adds UnaryOp AST node — misclassified, belongs in D.
Op-stratified (correct): J-J = 0.53-0.59 vs I-I = 0.87, D-D = 0.29. **J is INTERMEDIATE,
not D-like.** Whitespace inside expression is inert (loadings 0.79-0.86). Single-operand
parenthesisation partially non-inert (j_parens_first 0.40, j_parens_second 0.66) while
whole-expression parens nearly inert (d_parens 0.77). Neither adjacency nor semantic change
predicts this ordering; "rarity of resulting code form" fits but is untested.
NEW FINDING: `a // b` (2 spaces before `//`) read as C-comment on bare surface;
`# Python code` header restores floor division — surface disambiguates language (10x).
CAVEAT: cell rankings readout-specific (cross-readout correlation 0.04-0.72).
A-A, I-I, D-D recomputed on bit-identical data; deltas reflect only 2 swapped perts.
Note (R29): disattenuated AD is not D-specific; A is special (near-duplicate columns).
**R31 Stage 1 — SPACING/PAREN PERTS, CORRECTED (Qwen3-0.6B, 2026-09-20):**
5 new perts + 2 anchor re-runs (226s CPU, 98.8% accuracy, anchors reproduced to 4e-6).
Fable adversarial review: 1/6 claims survive, 5 withdrawn.
SURVIVING: p_double `((expr))` strat4=0.279 < d_parens 0.655, cell-level paired bootstrap
diff -0.376 CI[-0.60,-0.15]. Robust to artifact removal (strat3 diff -0.35 CI[-0.61,-0.08]).
WITHDRAWN: per-operator mechanism (// vs +/- within 1 SE), betwOp inversion (p=0.24 on n=6),
token-context refutation (0.670≈0.671 manufactured by `%` artifact), rarity dead (untested
as registered; both matched contrasts went rarity's way). CIs corrected (operator-level →
cell-level stratified bootstrap). Anchor ceiling corrected (0.924 → LOO 0.881, true A-A ~0.80).
LEADING ALTERNATIVE: header shielding — parens make the header redundant, depth-monotonically.
On `-`: mean dist A=33.6 → (e)=24.4 → ((e))=14.0, SD 10.0→5.5→2.1.
`%`-disambiguation artifact confirmed (same class as `//`-comment): `<digit>%` no-space triggers
percent-literal reading (7-15x distance). Spacing perts near-inert once artifact excluded.
R32 NESTING DEPTH: (((expr))) strat4=0.287 ≈ ((expr)) 0.279. Floor at depth 2.

M-shield holds through depth 2 on header-sensitive operators but all 4 operators show small mean distance INCREASE at depth 3. Floor is real, not pure monotonic compression.

- **WITHIN-OPERATOR STRATUM ANALYSIS (balanced v3, zero-cost, 2026-09-19):**

Gap SURVIVES and GROWS within operator strata:

| Metric | Qwen3 | SmolLM2 |
|---|---|---|
| Raw gap | 0.500 | 0.275 |
| Within-operator residual gap | **0.515** | **0.365** |

Operator strata SUPPRESS the gap, not create it. DD < AD in 5/5 (Qwen3) and 3/5 (SmolLM2) strata. d_add_zero and d_zero_plus (crossover D members) have LOWEST AD correlations (0.068/-0.171 Qwen3) — they're the least representative D members, NOT the gap's drivers. d_cond_true highest (0.584/0.839). R25's "operator strata reverse diagonal" was about anomalous D members on old cells; the gap overall is robust within operator strata.

- **HEADER RELOCATION TEST (Qwen3-1.7B, R22 E1, fp32 CPU, 2026-09-18):**

Moved `# Python code\n` from before code to after assignment. Tests whether C group's anomalous low correlations are header-adjacency or genuine position effect.

| Group Rho | Original | Relocated | Delta |
|---|---|---|---|
| A_A | 0.786 | 0.584 | -0.202 |
| B_C | 0.617 | 0.162 | -0.456 |
| C_C | 0.589 | 0.453 | -0.135 |
| A_D | 0.333 | 0.350 | +0.016 |
| D_D | 0.224 | 0.239 | +0.015 |
| Gap | 0.453 | 0.234 | -0.219 |

**HEADER ADJACENCY REJECTED AS SOLE MECHANISM.** Simple adjacency predicted C_C increase; it decreased. Header in the middle disrupts ALL correlations, not selectively adjacent ones. D_D and A_D barely changed — D perturbations are header-position-independent. Gap halved from 0.453 to 0.234: ~50% header effect, ~50% genuine A-D structural difference.

- **READOUT METRIC COMPARISON (4 models, zero-cost reanalysis, 2026-09-18):**

| Model | Full-logit gap | 11-bin gap | Cell-profile cross-readout rho (inert/D) |
|---|---|---|---|
| Qwen3-1.7B | 0.452 | 0.359 | 0.099 / -0.084 |
| SmolLM2-1.7B | 0.281 | 0.374 | 0.652 / 0.653 |
| StableLM-1.6B | 0.299 | 0.338 | 0.429 / 0.286 |
| CodeGen-350M | 0.318 | 0.190 | -0.438 / -0.476 |

Gap survives on 11-bin in ALL models. But Qwen3 and CodeGen have near-zero or negative cell-profile cross-readout rho — WHICH cells are sensitive differs between full-logit and 11-bin. Cell-level transfer claims must specify the readout.

**Cross-model perturbation rank correlation (full-logit mean distance):**

- Qwen3 vs SmolLM2: r=0.035 (near zero; 95% CI ~[-0.37, 0.43] at n=24, underpowered)
- Qwen3 vs Phi: r=0.203 (weak)
- Qwen3 vs StableLM: r=0.424 (moderate, p=0.039)
- SmolLM2 vs Phi: r=0.521 (moderate, p=0.009)
- SmolLM2 vs StableLM: r=0.523 (moderate, p=0.009)
- Phi vs StableLM: r=0.495 (moderate, p=0.014)

 Qwen3 is the outlier; SmolLM2/Phi/StableLM form a cluster (r≈0.5)
 Cell-level gradient correlates Qwen3-SmolLM2 (r=0.446, p=0.004) but not with Phi (r≈0)

**MULTIPLICATIVE FACTOR ASYMMETRY (8 models, zero-cost, 2026-09-19):**
The decomposition d[i,j] ~ f[i] * m[j] has fundamentally different cross-model structure
for each factor:

 **Perturbation magnitude m[j]:** cross-model rho = +0.397 [-0.17 to +0.77]. PARTIALLY SHARED.
Most stable: c_desc_comment (rank 23-24 in all 8), c_assert_before (rank 20-23 in 7/8).
C-group (before-position) always weakest. Group ordering: A ≈ B > D > C in 6/8.
Exception: Qwen3 family has D > A (rewrites MORE disruptive than inerts).

 **Cell fragility f[i]:** cross-model rho = -0.022 [-0.49 to +0.35]. COMPLETELY MODEL-SPECIFIC.
Even within-family: SmolLM2-135M vs 360M: -0.12. Qwen3-0.6B vs 1.7B: +0.03.

 **Implication:** you can partially transfer WHICH TYPES of changes matter (perturbation
magnitude hierarchy is ~40% shared) but you CANNOT transfer WHICH INPUTS are vulnerable
(cell fragility is ~0% shared). Alignment implication: general rules about change types
may generalize; per-input vulnerability maps do not.

**TOKEN SEGMENTATION DOES NOT PREDICT FRAGILITY ORDERING (8 models, zero-cost, 2026-09-19;
R23-corrected heading):**
SmolLM2 (49K vocab) and Qwen3 (152K vocab) have DIFFERENT tokenizers (26% vocab overlap,
different token IDs) but produce IDENTICAL segmentation of all 40 assignment lines (7 tokens,
same boundaries). StableLM/CodeGen/Phi have CONSTANT token count (zero variance).
Feature regression: $R^2$=0.41-0.84 per model (null expectation ~0.13-0.21 for 5+ predictors
at n=40). No feature has consistent sign across all 8 models, but P(all-8 agreement) ≈ 0.4
even under a true shared effect of rho=0.3 — the sign-consistency test is uninformative.
**R23 CAVEAT:** Fragility is 34-74% operator stratum (eta², KW p<.05 in 8/9 models).
Identity operations (n*1, n//1, 1**5) are confounded with operator class. Effective n ≈ 6
strata, not 40 cells. Double-operator feature was exploratory (post-hoc flag stands).

**CROSS-MODEL TRANSFER (8 models, zero-cost, 2026-09-19; R23-CORRECTED):**
Models: SmolLM2-{135M, 360M, 1.7B}, Qwen3-{0.6B-Inst, 1.7B}, StableLM-1.6B, CodeGen-350M,
Phi-1.5-Q1. Two of eight (CodeGen 32.5%, SmolLM2-135M 52.5%) fail admissibility. Qwen3-0.6B-Base
omitted from the 8 but included in Base/Instruct comparisons.

 **Cell fragility:** mean rho = -0.022 (model-level jackknife 95% CI [-0.09, +0.14]).
Heterogeneous: SD=0.23 vs null SD=0.16; 4/28 pairs significantly negative, 1 positive.
Mean flips sign with Phi-Q0 (+0.024). Qwen3-0.6B Base/Instruct (same architecture): 0.333
(p=.036). **Ceiling problem:** same-weights Phi Q0 vs Q1 fragility rho = 0.45 — if the
same model doesn't agree with itself across readouts beyond 0.45, cross-model 0.3 would
already be near ceiling. "Zero" is not established; "small mean, large spread" is.

 **Perturbation magnitude:** mean rho = +0.397 raw; 0.170 after removing A/B/C/D group means;
0.100 with C-group dropped. The shared component is the C-group (header-adjacent) magnitude
floor already identified in R17/R22. 16/28 pairs significant at n=24.

 **Profile transfer (0.326) carries no cell-specific information** (R23 correction): per-cell
profile rho against target model's mean profile (no cell info) = 0.356; against row-shuffled
target = 0.318. Cell-matched excess: +0.008. This is the magnitude correlation restated, not
a separate test.
**R23 NOTE:** All cross-model claims use cells with operator-stratum eta²=0.34-0.74 and
confounded identity operations; effective n ≈ 6 strata, not 40 cells. R21 required

operator-balanced cells (n≥60, no identity expressions) before any new cross-model claim.
That precondition was not met. The balanced cell set is the only admissible next step.

**WITHIN-FAMILY vs CROSS-FAMILY TRANSFER (8 models, zero-cost, 2026-09-19; R23-QUALIFIED):**

- **Magnitude transfer:** within-family rho = 0.678 ± 0.091 >> cross-family rho = 0.350 ± 0.260.

**R23 CAVEAT:** After removing group means, raw 0.397 → 0.170; with C dropped → 0.100.
The within-family advantage may also be C-group-floor dominated.

- **Fragility transfer:** within-family rho = 0.028 ± 0.095 ≈ cross-family rho = -0.030 ± 0.241.

Both near zero at n=40 (effective n ≈ 6 operator strata). Family doesn't help.
**R23 CAVEAT:** 4 pairs significantly negative — heterogeneous, not simply zero.

- No scaling law: param distance does not predict transfer (rho=-0.165, p=0.40).
- Qwen3-1.7B is magnitude-transfer outlier (0.174 vs others >0.29).

**R23 NOTE:** These patterns are on 40 cells with confounded operator strata. Cross-model claims require the operator-balanced cell set (n≥60).

**INSTRUCTION TUNING SEPARABILITY (Qwen3-0.6B Base vs Instruct, zero-cost, 2026-09-19):**
Qwen3-0.6B-Base magnitude ranking has rho=0.905 with Qwen3-1.7B-Instruct and rho=0.737
with Qwen3-0.6B-Instruct. Base-to-non-Qwen3 transfer = 0.186, Instruct-to-non-Qwen3 = 0.285.
Instruction tuning has TWO SEPARABLE effects:

- **Magnitude hierarchy:** architecture-determined, UNCHANGED by instruction tuning.

Qwen3 Base and Instruct agree on which perturbation types are strong/weak.

- **A-D gap amplification:** 1.5x increase (like-for-like; R23-corrected from 5.6x).

Instruction tuning doesn't change WHICH changes matter, but amplifies the DIFFERENCE
between meaning-preserving rewrites and inert modifications. n=1 pair; not yet replicated.
Qwen3 is a genuine architectural outlier in perturbation magnitude ranking (d_temp_var
ranked #1-2 vs #16 median in other families; b_dead_var ranked #18 vs #2 in others).
This explains why Qwen3 magnitude transfer to non-Qwen3 is low (0.08-0.29) while
within-Qwen3 is high (0.71-0.91).

**GAP MECHANISM (Qwen3-0.6B Base vs Instruct decomposition, 2026-09-19):**

| Component | Base | Instruct | Change |
|---|---|---|---|
| Within-A rho | 0.910 | 0.791 | -0.119 |
| A-D cross rho | 0.586 | 0.301 | -0.284 |
| Within-D rho | 0.394 | 0.169 | -0.225 |
| Gap (AA-AD) | 0.324 | 0.489 | +0.165 |

70% of gap increase from A-D cross-rho dropping. Instruction tuning makes D perturbations
(semantic rewrites) MORE IDIOSYNCRATIC — each rewrite affects cells in its own distinct
pattern. D-group absolute sensitivity DECREASES (0.69x) while within-D coherence drops
2.3x (0.394→0.169). The gap captures PROFILE DIVERSITY, not magnitude: instruction-tuned
models discriminate between meaning-preserving rewrites more finely, while treating inert
modifications more uniformly. Group-specific amplification: A=0.98x, B=0.94x, C=1.42x, D=0.69x.

**ROBUSTNESS: Tokenization-covariate regression (R17, zero cost):**

- Token-count delta between minimal/verbose surfaces is CONSTANT (4 tokens) across all 24

perturbations for 4/5 models. The only surface difference (`# Python code\n`) always adds
the same tokens regardless of perturbation. Qwen3 has 1 exception (c_newline_before, 3 tokens).

- R^2: Qwen3 0.347, all others 0.000 (degenerate — constant input). Below 0.5 threshold.
- **Per-perturbation distance variation is NOT a tokenizer artifact.** Variation is genuine model behavior.

**ROBUSTNESS: Operator-class test (R17, pre-registered, zero cost):**

 Pre-registered H1: D-sensitivity varies by operator class AND A-sensitivity does not.

 **H1 FAILED for all 5 models.** Both A and D sensitivity vary by operator (Kruskal-Wallis): Qwen3 (A p=0.003, D p=0.012), SmolLM2 (A<0.001, D=0.001), StableLM (A=0.002, D=0.024), Phi (A<0.001, D<0.001), CodeGen (A=0.022, D=0.319 NS).

 Operator class is COMMON FRAGILITY, not perturbation-type-specific. "Pattern structure" is empty.

 The gradient is amplitude-invariant by construction (Spearman). Group amplitude ordering is model-dependent (Qwen3 D>A, others D<A, all paired p<0.01) — a clarification, not a finding.

**R14 control experiment results (Qwen3-1.7B, fp32 CPU, 2026-09-18; CALIBRATED):**

 Groups: A (reference inert), E (unusual inert appends), F (inert assignment-line mods), D (rewrites)

 Full-logit ordering: A(0.785) > E(0.645) > F(0.471) > D(0.224)

 11-bin ordering: A(0.686) > F(0.583) > E(0.442) > D(0.182)

 E and F swap between surfaces in point estimates, but **bootstrap CIs include zero on BOTH surfaces** (fulllogit: +0.171 [-0.013, 0.355]; 11-bin: -0.138 [-0.341, 0.048])

 Within-group heterogeneity dominates: f_semicolon (0.872) > any E member; e_list_pop (-0.021 on 11-bin) < any F member. Groups E/F are not coherent classes

 Neither "computation path" nor "syntactic novelty" can be cleanly distinguished

 Individual perturbation identity matters more than any group-level factor

 Both surfaces preserve the core A > D gradient — the gap is robust regardless of readout

**Known limitations:** 11-bin is code-specific. Position confound PARTIALLY real (~0.2 contribution) but gap survives controls (kill experiment 2026-09-18). Qwen3 full-logit has fp16 resolution floor (60% distances < 1e-3) but SmolLM2 has ZERO sub-1e-3 distances, confirming the gradient is not a floor artifact. Phi-1.5 code was fp32 but NL was fp16 (precision mismatch invalidates cross-domain Phi comparison). Falcon-H1 (SSM-attention hybrid) experiment interrupted; not restarted due to battery constraints.
Single-factor "computation path" and "syntactic novelty" interpretations are BOTH refuted as sole explanations — the gradient is readout-dependent with at least two contributing mechanisms (R14 controls, 2026-09-18).
R15 CORRECTIONS: Position ordinal as FL predictor (r=-0.538, p=0.021 uncorrected) does NOT survive Bonferroni correction (10 tests). Mean distance as 11-bin predictor (r=-0.703, p=0.001) survives correction but is tautological (rank-SNR effect). "Two partially independent axes" claim downgraded to: one confirmed tautological predictor, one suggestive uncorrected predictor. d_eff analysis confirms earlier #19 dimensionality; not an independent finding (R13 already withdrew this).
RII significance: Pearson r=-0.944 (p=0.016) at n=5. z-RII/FDI claims RETRACTED (null artifact per R16 R2). But gradient survives both fragility partialling (residual gap 0.25-0.63 for 4 models, all CIs exclude 0; Phi 0.044 CI includes 0) and permutation null (Z=5.5-8.8, all p<0.001; Phi p=0.168 NS). The gradient is real perturbation-type structure.

Results: experiments/results/transfer_spectrum/. Fable R12 complete (fragility decomposition, held-out prediction). R13 complete (claim triage, kill experiment design). Kill experiment COMPLETED across 4 architectures (fp32 CPU — 2026-09-18).

---

**Prior work (paused 2026-09-14).**
Evidence reaches S65; S58 completed an independently reproduced CPU teaching precursor. Correct specialist pseudo-labels

improved a frozen-feature species head; soft targets offered no advantage over hard labels under the locked recipe. The [canonical next-work boundary](theory/CUMULATIVE_CAPABILITY_ACQUISITION.md#next-work-boundary) is authoritative for active allocation and closed/deferred episodes.

S59 declines an unmotivated hierarchical-classifier comparison. S60 adds external evidence for a jointly taught representation supporting later trained readers. S61 closes that source inquiry with behavioral coverage evidence and charged-reader repair requirements. S62 completed the later-attribute comparison: mean pair scores .631 for specialist features, .607 for full logits and .690 for existing recipient features on fourteen pairs. Predictions were independently reproduced. Selected visual checks qualify the labels' visibility. Close this panel; it does not justify requiring specialist features, nor prove general logit sufficiency. Next identify a useful contribution beyond existing recipient access and matched teaching.

S63 identifies an external temporal-service precedent and its attribution boundary: object association, persistent extent, memory and trained consumers are distinct contributions. Compare joint preparation against separate contributors with the same useful consumer. The source inquiry is complete; no large local reproduction.

S64 rejects unmotivated temporal-state migration and distinguishes recovery from composite segmentation gains. Existing-weight memory/search is a serious direct remedy; retrospective trajectory selection is not an immediate decision contract. The source selection is closed without local tracking reproduction.

S65 completed a three-case supplied-revision diagnostic. All 18 responses terminate; original citizenship is correct in 2/3 and supplied citizenship in 3/3, but capital prerequisites and supplied composed capital answers are both 0/3 (termination 3/3 in each arm). There are zero prerequisite-eligible cases. Manual reviewers confirm country-for-capital substitution and one wrong-subject citizenship misattribution. This is a scoped interface limitation, not missing knowledge or an intrinsic composition failure. First-attempt serialization failure and successful retry are preserved separately. The natural-question prerequisite remedy is unrun, not queued.

The shared-predictor branch needs useful second-donor acquisition evidence; its isolation and conditional cache arguments are already worked out. Connected use, structured consequence records and global policy revisions remain distinct routes. No cumulative acquisition, local concept-correction consumer or intrinsic latent space failure is established. Source-access failures do not establish model failure.

## Current direction: cumulative capability acquisition (2026-09-13)

Read the [canonical direction and decision map](theory/CUMULATIVE_CAPABILITY_ACQUISITION.md). The enduring philosophy is native latent mathematics discovered from a denizen's needs: identity, moves, effort, maps and laws. Native means coordinate-independent and effective; existing mathematics is welcome. Cumulative acquisition is the current direction within that mission, not its replacement.

Explore capability grafting, reasoning over encoder representations, and a persistent system that combines successive pretrained donors while retaining prior capabilities. Connected growth retains donor runtime; assimilation after

donor removal is a separate branch. Do not assume isolated capability modules,
a fixed shared vector space, training-free transfer or proprietary access.

**Mode on explicit user resumption:** strategy/discovery, authorized 2026-09-13 at
19:45 UTC. Definitions, primary literature and bounded CPU probes should resolve
decision-changing questions. No system-building, large-model loading or sustained
compute; per-run GPU approval remains. Consolidate before approximately two-hour
adversarial approach reviews. The first completed around 21:42 UTC (audit e1027);
the second completed around 23:03 UTC (e1039-e1040), and the third around
00:54 UTC on September 14 (e1061-e1062), after consolidation at 89b34ae.
Fourth review completed around 02:40 UTC (e1086-e1087), after e72f83d and a
separate entropy review. Strategy map review completed around 03:34 UTC
(e1095–e1096); retain the two-hour cadence
during subsequent substantive research.
The reviewer challenges approach and question selection, never the mission.

**Evidence status:** S58 establishes modest teacher-assisted species readout after
donor removal. No cumulative acquisition, transferable graft, encoder reasoning
artifact, new backbone knowledge or cost advantage is established.
The earlier four bounded probes sharpen the evidence requirements (S26 below);
current eight-block accounting is reported separately:

- **S6, retained exports:** legacy plan bundles are nonfinite or overwhelmingly
zero and unsuitable for the proposed transfer analysis. Underlying model
capabilities were not tested. Integrity audit e1011–e1012 upheld this scope.
- **S21, conditional port:** eight CPU forwards / 32 rows, no fitting. Four
isolated conditional rectangles fall below registered tolerances. Fresh real
Codex CLI audit e1021 found an additive preference class also fits the primary
tolerance; no useful conditional mechanism or global law is established.
- **S22, cached prediction screen:** the locked equal-rank combination loses to
the retrospectively better individual donor on four assays / 8,610 variants.
Fresh real Codex CLI audit e1022 prompted exact tie handling, now corrected in
the retained result and independently validated; the negative direction holds.
No complementarity-impossibility, latent-information or biological-use claim.

Exact provenance, qualifications and corrected numbers live in the
[experiment log](experiments/EXPERIMENTS.md), [ledger](experiments/ledger.jsonl)
and canonical S6/S21/S22. S23 is proof-only: pairwise compatibility need not
imply joint compatibility, and compatible marginals need not identify new joint
answers. It is an obligation for applicable interfaces, not a selected architecture.

**Closed task cases:** [Canonical S8/S24](theory/CUMULATIVE_CAPABILITY_ACQUISITION.md) preserve the PFN1
endpoint/receiver eligibility failure and the sufficient scoped-record contract.
The former is not a whole-benchmark or trained-model attribution verdict; the
latter does not settle broader capability composition. Coordinate repair and
caller-supplied continuation laws remain integration obligations. Source readings,
independent checks and decision chronology stay in canonical theory, NOTEBOOK
and the ledger; neither case is queued for extension.

**S26 result, independently audited (e1044-e1045):** the single autonomous-continuation probe

completed in 10.1455 seconds, seven CPU forwards / 112 rows, on 16 fixed pairs
nested in four assay reference constructs. All fixed-position cases completed;
repeat probability drift was zero. Primary and independent pair recovery were
both 0/16; second-site recovery both 2/16, versus cyclic content control 3/16.
The primary first proposal was correct only 1/16, bounding attainable pair recovery
below the locked .10 gain threshold. Close this procedure on this support; weak
proposals prevent a strong conclusion against competent composition. No parameter
fitting, new model, GPU or panel extension. Root read all 16 decoded outputs;
the fresh real CLI audit independently reproduced all counts and code-path checks.
Reverse and confidence-first each correct one prediction and spoil one; primary
corrects/spoils none. The 10.1455-second timing starts at main, excluding interpreter
startup; an external 180-second process wait also returned normally. Exact receipts
and the correction of the audit prose's runtime transcription are in the ledger.
This completed probe is not reopened. Preserve the broader capability-composition objective.

**Historical S50 decision (superseded by paused S65 routing above):** retain S50/S51 as source and operational evidence, then pivot
to a specific testable benefit of sharing or assimilating useful computations.
The fresh periodic review around 15:30 UTC distinguishes unchanged connected
extension from modification of an established service; replay is not automatically
needed for the former. It rejects another availability-driven substitution.
Next investigate cumulative assimilation of
fresh-input operations using already studied teaching recipes; ordinary teaching
and connected growth remain valid alternatives. No trained AB endpoint was
bound in the limited source check; do not extend the hunt or train a substitute.
Old-operation prompts and prompts produced by an acquired operation need separate
coverage. Repeated questions over one memory are not successive acquisition.
S40 supplies a connected-use precedent; S49 supplies a later-question memory
consumer and a complete trained-reasoning comparator. Their unresolved combination
is not a selected architecture. Useful contribution may be information, computation,
accessibility or effort savings; novel information is not mandatory.

See the [canonical next-work boundary](theory/CUMULATIVE_CAPABILITY_ACQUISITION.md#next-work-boundary).
S37 stays parked, S43/S47 stay closed, and the S49 small-checkpoint branch is closed
without download or execution. No new model run or apparatus is queued.

**Session accounting:** 1710 apparatus / 0 reusable artifact-bearing code lines
(98 + 119 + 204 + 207 + 330 + 107 + 286 + 222 + 137); nine probe blocks / zero building rounds.
S37 has two failed execution attempts and zero scored forwards. There are 666 recorded
forward calls: 15 earlier batched, 540 single-image S58/S62 and 111 S65 retry calls.
S65's failed first attempt adds an unrecorded 1–16 calls: total bounded 667–682.
S58 fits twelve candidate linear heads in 2400 optimization steps; S62 prepares
45 ridge readers (36 nonconstant and nine constants). No GPU. No reusable acquisition
component was built. S43 separately inspects32 published
responses on16 matched queries; it adds no local model inference. The explicit strategy mandate
supersedes construction merely to change this ratio.

**Continuity and custody:** commit-seal rung 1 stays paused; closed lines stay
closed, and the strong-assert panel is a deferred option. Historical quota dates

are not current access checks. Root alone writes the blackboards because separate MCP sessions reused IDs; reviewers return findings for provenance-preserving relay. Mission synthesis is skipped under its known large-board hang workaround. Real CLI result audits require a working fresh CLI. Under the latest restart workaround, available independent strategy/data reviews are labeled accurately and do not halt over inaccessible tooling. Dated session checkpoints remain in NOTEBOOK.md and the ledger rather than being repeated in current routing.

## Historical state below

The following dated record preserves the prior direction and audit decisions. Its next-step and current-direction language is historical; use the entry above for present routing. Numerical claims remain subject to their latest corrections.

## Prior direction: Selective Write-Boundary Construction (2026-09-04)

**Pivot (Codex direction dialogue, 2026-09-04):** Close the pretrained-Qwen path-dependence line. Skip CEG-1R — its outcomes produce no different program decisions (both paths lead to construction). Measurement-to-artifact ratio was infinite (506:0); governance required halt above 5:1.

**Central question:** If a model is given an internal "replace this fact" operation (an endogenous keyed write with hard-masked overwrite), does compositional reasoning become possible because dead history is truly dead?

**Anti-tautology constraint (Codex):** The write boundary alone is NOT the artifact. Boundary satisfaction is by construction. The claim-bearing results are: (1) learned use of writes for compositional reasoning, (2) predictive compression — |Q_H| bounded by store cardinality not history length, (3) transfer across held-out presentations, (4) causal substitution of store-equivalent states, (5) advantage over matched append-only ablation.

**Theory:** theory/CONTINUATION_REFINEMENT.md, CR-10 through CR-14. Laws L1-L4 (overwrite absorption, cross-register commutativity, preservation, write fidelity). The last-write normal form bounds the write orbit from one initial place by ∏_r(|V_r|+1). With faithful native reads, an actual complete initialization gives exactly ∏_r|V_r| places. These statements do not bound the entire predictive carrier when preserved context varies. Five pre-declared falsifiers.

**CR-14 revised (2026-09-04):** Original hard-register design was EAC tautological (Codex correction). Replaced with commit-seal carrier: hard seal (information bottleneck) + learned update U(m, address, proposal) → m+. The model CAN fail — the learned update is the falsifiable object, not the hard-wired register semantics. WB-1 validates the normal form math but is architecturally tautological. Positive-control staircase: 1 address, 2 values, 2 commits first.

**Narrative gate:** "Give a model an internal act that genuinely means 'replace this fact,' then test whether compositional reasoning becomes possible because dead history is truly dead."

**Status relative to the central claim:** CR-15 supplies conditional behavioral structure and sufficient certificates. It establishes no learned realization, transfer, causal-substitution result in a learned model, or advantage over an append-only alternative. Those remain the claim-bearing obligations.

**Mode since 2026-09-05: analytical (compute-constrained).** Work is derivation and proof; runs only for tiny models when a derivation needs a concrete check. Rung 1 of the commit-seal staircase ran 2/5 seeds (both arms passed every mechanism gate; stale partial deleted, weights not saved) and is paused, not closed.

**CR-15 adopted (2026-09-05, theory/CONTINUATION_REFINEMENT.md):**

- Under A1-A3, each T-saturated subset is canonically B_T x S_T as a set equipped with its T-write action. The general write-orbit bound from one initial place is ∏_r(|V_r|+1). An actual complete initialization gives exactly ∏_r|V_r| places. Numerical initialization alone does not imply saturation, and preserved context B_T may be infinite.
- Transition-closed realization sets with η-accurate registered response laws give a history-independent 2η bound whenever the compared histories have the same abstract endpoint. Preserved abstract distinctions require margins exceeding 2η. Small local absorption errors alone do not provide a vanishing history-uniform error bound (cyclic-counter counterexample in CR-15.2). A greatest tolerance-compatible relation need not be an equivalence relation, and a coarsest tolerance-bounded congruence need not exist (three-state counterexample in CR-15.2).
- Contraction supplies invariant sets (surgeon certificate): per-value contraction with verified invariant domain and initialization coverage gives radius kappa D/(1-kappa) balls; selective-tube version for multiple registers requires exact preservation of unaddressed coordinates and contraction uniform over them. Fibered contraction with consistent fixed points does NOT imply commutation (explicit counterexample).
- Selective memory requires selective forgetting: a global behavioral contraction under every write is incompatible with indefinite preservation of an unaddressed register.
- A constant, address-independent sigmoid gate CAN realize exact selective overwrite (address selection in the candidate); keyed gating is not a theorem-level requirement.
- Withdrawn: "positive attention mass on dead tokens forces a nonzero absorption defect". Surviving restricted obstruction: with one bounded-logit softmax route the LIVE value's influence dilutes like e^B/(m+e^B) (fidelity, not absorption, fails with history).

**Status relative to the central claim:** CR-15 supplies conditional behavioral structure and sufficient certificates. It establishes no learned realization, transfer, causal-substitution result in a learned model, or advantage over an append-only alternative. Those remain the claim-bearing obligations.

**Accounting:** This is an analytical cycle with no runs. Zero runs does not determine the apparatus-to-artifact code-line or round ratio; those classifications must be reported separately.

**Audit #39 (2026-09-05): REVISE.** Mathematical core of CR-15 retained (15.0, 15.2, 15.3, 15.5, 15.7 ADOPT; 15.1, 15.4, 15.6 REVISE, corrections applied verbatim). Withdrawn from every surface: "distance from claim 0" and "pretrained transformers lack an endogenous overwrite boundary". Licensed sentence: under a fixed registered deterministic interface, exact selective-write laws yield a context/store factorization on write-saturated states, and a transition-closed, η-accurate realization of an abstract write system bounds equal-endpoint histories by 2η under every registered continuation; CR-15 supplies sufficient contraction certificates and an exact constructed gated-cell example, without establishing learned realization, transfer, or architectural advantage.

**CR-15.8 — audit #40: mathematical core ADOPT; parameter and attribution clarifications applied.** Fix one initial behavioral place and the registered deterministic interface. If its entire write orbit contains at most N exact behavioral places and absorption and commutation defects are uniformly at most ε in the full behavioral metric, equal-normal-form histories differ by at most $B_N = \min\{1, (N-1)\varepsilon\}$ under every common registered continuation. No additional factor two is required. With native own-write calibration error β, a sufficient live-value separation bound is $\Delta - 2(B_N + \beta)$. The worst-case error has order $\min\{1, N\varepsilon\}$; the binary example preserves its live value exactly while accumulating nuisance-response error. The exact envelope is attained when singleton-valued registers are permitted, with zero cases handled separately. A full-behavioral packing bound gives $\min\{1, N\tau + (N-1)\varepsilon\}$, and $N\tau$ can be attained for arbitrarily small positive defects. Finite state, packing, contraction certificates, invariant relations, and ultrametric behavioral distance provide sufficient routes to uniform bounds; no exhaustive or disjoint classification is claimed. These results establish no learned realization, transfer, or architectural advantage. Corrected en route: \"identity cost $c_\tau = 0$\" does not characterize overwrite, and append-only storage does not universally violate uniform reader accuracy.

**Next obligation

**Certificate check (2026-09-05; evidence gate REVISE):** the registered single-cell attempt remains CERTIFICATE_INCONCLUSIVE. Separately, the sound post-hoc confirmation procedure reports strict expansion for both writes on $D=[-1,1]^{16}$ in the infinity norm. This is a scoped contraction-premise failure, not a behavioral overwrite failure. Verifier defects (fixed after the run, not rerun) prevented accepting the implementation as a general PASS verifier. The eight-cell training-panel accuracy is 1.000, with maximum immediate-read paired TV approximately 1.4e-8. Jacobian norms 0.987 and 0.539 are numerical diagnostics at 64-step candidates, not certified contracting regions. No history-uniform behavioral bound is established. Details: experiments/EXPERIMENTS.md.

**CR-15.9 adopted (2026-09-05, pending audit; register-free CR-15.8):** for any deterministic action alphabet on a behavioral metric space, an orbit of at most N exact places, nonexpansive actions, and a finite family of word equations each holding to within ε on the orbit, two histories equal in the least congruence generated by the equations are within $\min\{1,(N-1)\varepsilon\}$ under every registered continuation. No registers, stores, or normal forms are assumed. Finite orbit is sufficient, not necessary (an infinite-orbit contracting world has arbitrarily small lifetime error).

**Re-contextualization ruling (Codex, 2026-09-05):** the program continues;

the selective-reset/state-budget certification line is NOT currently the highest-leverage route to a real-model artifact ("not working yet" as a route; the mathematics is retained as transferable constraint). The "von Neumann trap" (imported addressed-register semantics certified as discovery) is substantially real; native vocabulary = actions, response distinctions and the continuations that reveal them, distinctions an action erases/preserves/exposes, contextual equations with explicit error and observation scope. Next cycle (direction dialogue, round 2 of 3): one explicit rule for when an erased distinction stays irrelevant under subsequent actions, anchored to the real-model CR-9 examples, with a counterexample and an intervention consequence. Discrete-carrier testbed deferred; no run.

**Locked direction (direction dialogue rounds 1-3 complete, 2026-09-05): CR-15.10.6, ANALYTICAL_ONLY.** Interface-relative interchangeability with the modulus ω_a^W(t) as organizing quantity. The next cycle is one bounded analytical construction: (1) moduli for the contrast worlds (countdown ω = 1 at every finite depth; doubling ω = min{1, 2t}; CR-15.5 selective write θt on the addressed fiber; CR-15.9 decaying nuisance ½min{t, δ}); (2) the finite-panel bounding proposition; (3) the finite-observation obstruction for unrestricted deterministic worlds; (4) one explicit sufficient premise that lets finitely many questions yield an UPPER bound on ω (the substantive gap: CR-15.2 bounds pairs in the same realization set, not every W-close pair; CR-15.3 needs an observability premise in the other direction, small d_W □ small carrier separation). Real-model panel DEFERRED: the historical CRC-0 panel has zero eligible W_H-close same-variable pairs at τ = 0.01, P2's presentation is malformed (`func` vs `f`), and no model in play is "tiny" under the directive; any acquisition needs explicit approval and the locked criteria in CR-15.10.6 (τ = 0.01, numerical guard m, five robust-close pairs over five task blocks, affine and length-only rivals tested separately by interval-aware infeasibility, verdicts WITNESSED / TOLERANCE_PRESERVED_ON_PANEL / INCONCLUSIVE).

**CR-15.10.7 (audit #41: REVISE, corrections applied):** finite-panel enclosures, corrected declared-domain moduli, and the refinement identity are retained. Response-only finite transcripts cannot establish a nontrivial global bound over unrestricted extensions; independently justified completeness or structural premises can. The contraction route requires Lipschitz control of full question profiles and a uniform inverse bound on the declared carrier domain. Saturation can degrade conditioning without making inversion impossible. Local rank does not establish a global inverse bound or PSR dimension. Neither the saved cell's retained-history mechanism nor W_H's rank has been established. No new learned realization, generalization result, or native mathematical novelty follows. Withdrawn: the original obstruction theorem, the saturation impossibility, the global rank bound and both dimension extrapolations, the cyclic parity claim.

**Question rotation (Devansh, 2026-09-06: never idle; rotate to a different analytical question when a line closes).** Block 1 = CR-16, architectural restrictions of the transformer world. Audit #42: RESTATEMENT; CR-16 requires corrections. Fixed-token causal site invariance and, with consecutive positions, the appended-token offset identity are retained. The exact two-route decomposition, content-independent prefix re-weighting, filler-effect subtraction and identification with CEG-1 RELAY-CUT are withdrawn. CR-15.10.6 already requires matched positions, valid tokenization boundaries and the registered H-versus-F rival. Close Q1 and rotate to one bounded Q4 reading of existing audited response tables under their original interface and claim limits, with no runs or new acquisition.

**Block 3 reading, evidence gate REVISE (2026-09-06):** on the archived multifiller panel (24 roots, positions matched by construction, 11-bin immediate-read TV, assumed floor) H and its matched successor filler violate the 0.002 length-only prediction on 24, 24, 23 roots across three filler variants: conditional LENGTH_ONLY_RIVAL_REJECTED at that channel; unqualified locked-interface verdict INCONCLUSIVE. The "between-filler spread" reference was confounded (each filler pair varies input and successor together; off-diagonal endpoints absent), so "H is not distinguishable from an arbitrary equal-length comment" and "content-specific H disfavored" are withdrawn; generic readout sensitivity remains unexcluded, not confirmed. Decision: future panels need several response-independently selected successor fillers on fixed input pairs; the deferred panel's discrimination against the readout-sensitivity rival is unestablished. Ruling: stop zero-call rotation pending compute approval; prioritized acquisition = position-matched, full-law, eligibility-first panel on repaired strong-assert pairs (five task blocks; measure floor; five robust W_H-close pairs required; then N/H successors and three fixed-input successor fillers). Details: experiments/EXPERIMENTS.md.

**Block 2 (Q4) reading, evidence gate REVISE (2026-09-06):** on the archived unequal-position svb_qwen3_congruence panel (Qwen3-1.7B-Base, 24 cells, 11-bin TV, assumed numerical guard), the neutral comment keeps all 32 initially close assert-type presentation pairs below 0.01 while the heavy comment separates 29 (arithmetic verified exactly by the gate). Under the locked CR-15.10.6 interface the verdict is INCONCLUSIVE (surfaces of a pair differ by 1-3 tokens, so positions are unmatched; floor unmeasured; no pinned revisions). Decision (amended): prioritize strong-assert as the candidate family for a NEW position-matched full-law eligibility panel; moderate-assert as boundary diagnostic; N-preservation and H-separation are W_0-level hypotheses; the deferred panel is not replaced (only three W_H-close pairs over two blocks exist in the archive). Q4 ruled decision-relevant. Next block (Codex): the multifiller table's filler-versus-surface comparison on its own roots, after verifying token matching and endpoint availability; if non-actionable, rotation stops pending compute approval. Details: experiments/EXPERIMENTS.md.

**Program ruling (audit #41):** the analytical cycle CR-15.10.6 STOPS after this consolidation pass; wait for approval of an empirical step capable of changing a program decision. Further solo theory expansion is not the highest-leverage work; "this is not working as a route to a real-model

artifact." The valid mathematical residue is retained; the wider program remains open.

**Withdrawn en route:** the "P vs R" mechanism dichotomy (not mutually exclusive); the CV-of-ratio rival rule (b/d = g + c/d makes spread uninformative); "immediate-read family closed under N".

**Standing check (Codex):** this is established behavioral mathematics, not discovered native vocabulary; value must come from effective predictions about a real model. A proven observation hole identifies an inadequate interface, not an obstacle to structured reasoning in the model.

**So what:** find which differences between an AI's histories it can safely ignore, and which later question makes those differences matter again.

**Closed lanes this cycle:** single-cell contraction certificate (evidence gate: no further run; apparatus ratio 5.71:1); commit-seal rung 1 remains paused (2/5 seeds, no saved weights); discrete-carrier testbed deferred.

**So what:** if a model has a proved limit on its distinct behavioral situations, small update mistakes cannot accumulate beyond that limit times the local error, even after a million updates.

---

## Qwen path-dependence line: CLOSED (2026-09-04)

CEG-1R remains a deferred diagnostic. The tested interfaces did not establish a useful overwrite law. CEG-1 supports bounded attention-mediated context dependence after a failed competence preflight; it does not prove that pretrained transformers lack endogenous behavioral overwrite. The construction program investigates whether an explicit write boundary provides a useful alternative.

---

## CEG-1 result: REVISE / formal NO_INTERFACE — bounded context dependence (2026-09-04)

**CEG-1 (Codex strategic design):** Custom 4D attention masks on Qwen3-1.7B-Base (eager attention, full forward passes). 16 fixed-slot histories × 4 identifier sets, 6 intervention arms. 914 forwards, 259s CPU.

**Verdict (Codex Evidence Gate, audit #38): REVISE.** The original RELAY headline does not pass. Competence preflight failed (83.6% < 95% threshold); the binding design required NO_INTERFACE. RELAY-CUT Δ=0.000 is tautological (all downstream positions see only pair-identical tokens once the cut disconnects the graph).

**Licensed sentence (Codex, verbatim):** In this fixed-slot Qwen3-1.7B-Base panel, changing overwritten assignments altered normalized binary response profiles, and after direct query-to-early-span attention was cut an indirect, identifier-consistent excess over matched dummy cuts remained (mean max-channel TV excess 0.101); however, the residual was channel-nonspecific and observed after a failed competence preflight, so CEG-1 identifies bounded attention-mediated context dependence, not semantic relay of dead information

in competent computation.

**Key numbers (post-audit):**

- OPEN Δ=0.406 (accuracy 83.6%; r0=71.9%, r1=95.3%)
- QUERY-CUT Δ=0.194 (accuracy 64.1%; channel specificity disappears)
- RELAY-CUT Δ=0.000 (accuracy 100%; tautological by mask design)
- LIVE-CUT Δ=0.934 (positive control)
- SYNCHRONIZER Δ=0.267 (accuracy 89.1%; one string rejected, not synchronization)
- Dummy OPEN Δ=0.105 (accuracy 96.1%)
- Paired excess (QUERY-CUT minus DUMMY-CUT): 0.101, bootstrap CI [0.050, 0.152]
- Target vs orthogonal excess under QUERY-CUT: 0.062 vs 0.061 (nonspecific)

**Audit corrections adopted verbatim:**

1. RELAY-CUT=0 is a tautology of the intervention, not an empirical finding.
2. The "52/48 pathway split" used arm-specific maxima across channels and cannot support an additive decomposition. Dummy-adjusted ratio is 33/67.
3. Under QUERY-CUT, register-specific dead-value effect disappears: target and orthogonal channels show equal excess over dummy. The residual is broadcast context sensitivity, not semantic relay.
4. Four "renderings" are one syntax with four identifier pairs — name robustness, not held-out template generalization.
5. SYNCHRONIZER rejects one string, not synchronization or irreversibility.
6. Design omitted target/orthogonal effects, empirical CDFs, clustered bootstrap intervals, full-vocabulary accuracy, replay noise, and model revision binding.

**Never say:** "Dead information persists through attention relay into live-write representations; roughly 48% is relayed, and the failed synchronizer shows that this relay is irreversible."

**Measurement-to-artifact ratio:** 506 apparatus lines to 0 construction lines (infinite). One-more-test cap is binding.

**Line closed.** CEG-1R skipped (Codex direction dialogue: decision value nil). Qwen path-dependence line closed. Transferable finding: the tested interface did not establish behavioral overwrite; the broader architectural question remains unresolved. Construction program opened (CR-10+).

---

## CRC-1 result: INVALID / bounded negative (2026-09-04)

**CRC-1 (Codex Architecture Theorist design):** Two binary registers, 32 roots (8 per store), 4 literal actions, task-aligned {0,1} observer. 1508 forwards, 357s CPU. **INVALID** (competence 87.5% < 95% threshold). Identity partition ($Q_1$=32), zero compression at all tolerances (min $D_1$=0.099), algebraic relations 25.9% (idempotence 37.9%, absorption 20.7%, commutation 19.1%).

**Licensed sentence (Codex-corrected):** In the tested Qwen3-1.7B-Base interface, semantically cofinal assignment histories induced distinct conditional binary response profiles; because baseline competence was 87.5% and the principal law comparisons were not position-matched, this does not yet prove that correctly executed overwritten facts remain causally active.

**CRC verdict (combined CRC-0 + CRC-1, Codex strategic review):** Two experiments, two task families, two observers. Both identity partitions. CRC-1 removed CRC-0's strongest design excuses (fine observer, root-dependent actions, no guaranteed collisions) and still landed far from compression. CRC on Qwen3-1.7B-Base is **closed** as a discovery engine. Retained only as a downstream assay if a future method discovers a plausible synchronizer.

**Codex adversarial corrections (adopted verbatim):**
1. "Competence failure makes it more decisive" is scientifically wrong — invalid data cannot strengthen claims about competent computation.
2. Normalized {0,1} is not "the coarsest possible observer."
3. Q_1=Q_2=32 is trivial, not meaningful tower stabilization.
4. Algebraic relation rates are confounded by length, position, competence.

**Cross-framework convergence:** CRC-1 (Qwen3-1.7B, Python) partly replicates predictive_setter_algebra_v1 (Qwen3-0.6B, NL) primacy findings. Extends that failure class to 1.7B and a probabilistic binary observer.

**Competence position analysis:** 100% correct when queried register's last write is the final line, 75% when it's not. All 8 failures predict the overwritten value. Positional structure, not yet causally localized.

**Next: CEG-1 (Causal Erasure Graph v1).** Characterize the causal support of path dependence via attention mask interventions. Where does dead information live: direct KV access, relay into later states, or no legal synchronizer? 16 histories × 6 intervention arms × 2 channels. ~800-1000 CPU forwards. Codex design: `.codex_post_crc1.txt`.

---

## CRC-0 result (2026-09-04; interpretation revised by audit #41, 2026-09-05)

The historical CRC-0 panel (Qwen3-1.7B-Base, 36 roots, words ≤ 2 over {N, H, R}; numbers in experiments/EXPERIMENTS.md and docs/STATE_ARCHIVE_closed_lines.md) had no distinct same-variable W_H-close pairs at $\tau = 0.01$, giving no positive preservation evidence. The recorded closure score had zero coverage and did not test successor W_H profiles. Two retained same-variable witnesses violate immediate-tolerance preservation under H. These finite numerical summaries establish neither exact quotient stabilization nor absence of compact structure elsewhere. Earlier wording ("no closure", "tower stabilizes", "apparatus works", "almost compressible", task family exhausted) is withdrawn.

## Archived claims

Every section below this point in the original STATE.md was moved verbatim to docs/STATE_ARCHIVE_closed_lines.md (2026-09-05). Index (name, dates, verdict word as written in each section header):

- NLM-007 — adoption-order record (Rounds 1–34; superseded orders kept verbatim), including the NLM-001 through NLM-006b verdict/lock sections, Rounds 10–33, audits #2–#20, and the four-cell evidence gate (2026-08-27 — 2026-08-29)

**HP-G progress (2026-09-23):** G1-G3 complete — exact mean, contraction-operator covariance (Wick instance verified 0.989), triple-brute-force-certified variance counting, and the corrected L2 concentration criterion (matching stored gauss-arm data 0.0673 vs 0.0708; an ordered/unordered algebra slip caught by G5 validation itself, exhibit retracted). G4: the Gaussian universality class has a dimension-dependent stability boundary — **eta*(d) ~ d^{-1/2}** (crossover when the localized component's eta^2 d ~ 1), confirmed by pre-registered bracketing at d = 512, 2048, 8192, 32768 with the pinning cell landing inside the predicted bracket. Formal Lipschitz proof of the operator-level mechanism remains. This is the program's first dimension-asymptotic phase law for a universality class: direction ensembles within eta of Gaussian (in the contraction-operator sense) share the sharp interference frontier; beyond it the frontier broadens.

## Entry 127: The hierarchical family closes — disjointness gates the CGF regime (2026-09-21)

The candidate-B arc completed its full empirical cycle in one session, including a caught-and-fixed construction bug (ancestor encoding and block-size divisor mutually inconsistent; the kernel was never stochastic; first run invalidated honestly; lesson recorded — assert normalization before derivation-support numerics). Corrected results: the excess curve is smooth log-convex steepening to EXACT zero at the representability rank (32), not a staircase (P1 refuted); log-convexity holds throughout (P2); the Fisher recursive-tail envelope is tight far below representability (1.08-1.28x) in both rho arms with the by-now-familiar super-quadratic efficiency near the knee (to 0.02). The steeper-pi probe (pre-registered) was DECISIVE: the family cannot reach the CGF large-deviation regime at any steepness — every pair shares the root, so contrasts stay bounded. Scoped observation (review-8 correction): within the two constructions tested, the nested family stayed in the Fisher regime — plausibly construction-forced via the shared-root likelihood floor, not evidence of a general overlap law. The quantitative overlap-parameter theorem (max log-likelihood ratio / Rényi-type parameter, with an overlapping-family falsifier) is the adopted follow-up. Five complete structures now stand.

Ledger: hpb2_staged_not_run, hpb2_construction_bug_fixed, hpb2_cycle_scored, hpb2_steeper_pi_decisive. Theory: HPD sections 13-13g.

## Entry 126: Candidate B derivation program complete (2026-09-21)

The hierarchical-kernel arc (review-7's second-ranked direction) now has a complete derivation chain, all numerically anchored: nested-bump orthogonality (tree property) -> exact level-bundle spectrum (rank 2^L-1 confirmed to the digit; multiplicities (b-1)b^{ell-1}) -> bundle-scale law sqrt(m_ell) Delta_ell (geometric under geometric pi, matched) -> recursive-tail excess curve (level envelope x within-bundle Zipf block-mass tails — interpolating both validated regimes of the program in one object with an EMERGENT knee) -> CGF crossover with the phase boundary located (where the last strongly-gapped level falls below truncation rank).

The family's (pi decay, s) plane spans the real-model exponent range — a laboratory for the compression theory across observed exponents. The pre-registered simulation (stepwise curve, within-bundle tails, crossover location) is designed and gated on the next review's verdict.

Standing picture: FOUR complete theoretical structures — aggregate interference (exact + validated), Orlicz compression (exact identity + two-regime law + certificates), birthday limit laws (exact covariance + classification), hierarchical compression (this entry) — plus corpus assets for the gauge-safe observational side, HP-B closed with full provenance, and the review cadence as the empirical gate.

Ledger: hpd_candidate_b_spec through hpd_cgf_crossover.

## Entry 125: The limit-law arc — birthday structure, exact covariance, λ²PR_W (2026-09-20)

The review-7 lead arc closed its foundation cycle in one session: (1) the two-corner insight (dense corner governed by channel-mass PR; sparse-birthday corner by a third-moment PR); (2) the registered corner thresholds tested — 2/4, with both failures informative (gradual-in-PR boundary; total-intensity condition); (3) the zero-parameter Poissonized prediction REFUTED 2/12 — fixed-k conditioning is load-bearing, not a le-Cam correction; (4) the EXACT multinomial covariance derived ($(n)_2^2$ factorial-moment calculus; negative cross-covariance term) and VALIDATED 12/12 with ratios 0.76–1.09; (5) the law-class quantity identified: $\lambda^2 \cdot PR_W$. Remaining: the CLT statement proper (asymptotic normality beyond second moments — multivariate occupancy CLT literature applies) and the G-to-CP boundary as a theorem rather than a closed-form computation.

Ledger: hpe_limit_law_arc_opened, hpe_limit_law_two_corners, hpe_limit_law_validation, hpe_lindeberg_sweep_refuted (row restored after a repair-loop drop — both incidents logged), hpe_fixedk_validated, hpe_law_class_asymptotics. Theory: HP-E sections 4–4f.

## Entry 124: Strategy memo for the next review — four candidate arcs (2026-09-20)

The two theorem families are complete to their current levels (HP-E: aggregate-interference frontier, mean + sharpness + burn-in, all validated; HP-D: Orlicz compression, Fisher law + large-deviation structure + certified strict-local optimality, global duals exhausted with structural lessons). Candidates for the next arc, ranked by my current assessment:

A. **First-principles real-model spectra (connective; high leverage).** The validated compression theory IS the theory of what CE training does to a structured kernel. Apply the Fisher/CGF laws to REAL co-occurrence kernels (the HP-C1 WikiText corpus asset is prepared and tokenized for three models) and predict real-embedding spectra from first principles — the original "why power laws" question, now with a validated mechanism to apply rather than slopes to fit. Delivers the program's first theory-first account of real-model structure.

B. **Hierarchical/random-graph kernels (review-6 move 3).** Replace the construction-forced knee with growing-kernel families; derive CE distortion asymptotics before simulation. The honest version of the T4 phase question without the trivial knee.

C. **Structured-feature interference hierarchy (review-5 move 3).** Extend HP-E from isotropic/localized directions to trained-feature ensembles — effective-rank/cumulant versions; when does the PR frontier survive real feature geometry?

D. **Simplex-native global optimality (research-grade).** The one untried certification route; mathematically deep, uncertain payoff.

My ranking: A > B > C > D, because A converts everything built so far into a confrontation with real data through a validated mechanism, exactly the mission's test. The review should attack this ranking.

## Entry 123: The Orlicz arc — softmax compression is not low-rank approximation (2026-09-20)

The chain, verified link by link: exact CGF identity for KL (logit residual cumulants) -> settled-optimum decomposition showing the argmin itself changes (7x variance accepted for negative-skew structure; 12 seeds within 0.0005) -> envelope degeneracy (variance nearly irrelevant; exponential moment governs) -> DV-duality core (self-consistent tilted SVD; Fisher law = degenerate-tilt fixed point) -> corrected and NUMERICALLY VERIFIED first-order condition (gradient entirely in the complement block, 1.0000 — E-Y orthogonality survives the Orlicz metric) -> dual-attempt withdrawal with the structural lesson (no norm geometry => no E-Y dual; simplex-native theory required).

Program meaning: the question "what does rank-d softmax compression cost" has a genuinely nonlinear answer whose leading quadratic term (Fisher/E-Y) is provably wrong by 6x in the large-deviation regime — and the correct object (the CGF of the residual) has no quadratic analogue. This is the first structure in the program with no R^n counterpart in the classical low-rank toolkit. Two scheme failures logged honestly (metric-reweighting; unconstrained dual) — both informative about the geometry.

Ledger: hpd_cgf_identity, hpd_cgf_decomposition, hpd_variance_kl_envelope (withdrawn), hpd_orlicz_correction, hpd_dv_core, hpd_tilted_svd_probe_invalid, hpd_first_order_characterization, hpd_first_order_verified, hpd_dual_attempt_failed. Theory: HPD sections 12-12i.

## Entry 122: HP-D becomes quantitative — representability at exactly B, Fisher-metric compression law (2026-09-19)

**Representability settled (review-5 repair executed).** The planted-block kernel has exactly B distinct conditionals, so its centered log-kernel has rank exactly B (1e-15, 4/4 configs; my B+2 mixture story was answering an irrelevant question — retired). Untied softmax: exact zero-excess CE representation iff d >= B. Row geometry: shared mean u + disjoint orthogonal bumps v_b; block usage enters through the singular spectrum sqrt(n W_b)||v_b||.

**Fisher-metric compression law (the quantitative core).** The inf-norm lemma overestimates 10-30x because KL hides logit residual where P_ij is

small; the tight second-order object weights entries by sqrt(W_b P_bj)
(context mass x conditional mass = softmax Fisher metric):
excess_CE(d) ~= half the tail Fisher energy beyond rank d (Eckart-Young).
Validation (B=8, 8 points): 4 within factor 1.2; deviations regime-structured
— underestimation far below the knee at steep s (large-deviation KL; 20-seed
diagnosis running), one optimizer-beats-quadratic near the knee (s=.5,d=4,
rho=.7 — nonlinear CE can be smarter than second order). Knee at d=B in
16/16 cells; rho-sensitivity falsifier survived (excess ratio 2.8 for
rho .3->.7). B=32 Fisher predictions committed BEFORE their rows exist
(fisher_preds_B32.json) — a clean forward test of the law.

**Program state.** HP-E: isotropic quadratic theorem complete (exact
mean+variance, two phases); E-struct participation-ratio capacity
k* = Theta(sqrt(PR)), power-law corollary d^{1-alpha} — validated. HP-D:
chain now quantitative end-to-end in its validated regime. Open units:
s=1 nonlinear theory, B=32 scoring, fixed-quantifier E3, E2a intermediate
band, HP-C1 measurement (paused), T4 phase-boundary claim (awaiting locator).

Ledger: hpd_representability_settled, hpd_fisher_compression_law,
hpd_fisher_rho07; theory/HPD_ALLOCATION_THEOREM.md sections 8-11.

## Entry 121: Review-2 pivot — allocation theorem opened; four overclaims corrected; prior-art gap confirmed (2026-09-19)

**Review-2 (scheduled Droid, goal-aligned).** Verdict NEEDS-CORRECTION. Four
overclaim fixes applied verbatim to STATE/README: (1) the
"representation-computation gap" (exp(d) storage / √d linear / O(1) bilinear)
is void — no universal capacity law exists without task/decoder/noise/error
specification (orthonormal features give exact bilinear k ≤ d); (2) α* = s/2
has no eigenspectrum or d→∞ interpretation; (3) "RESOLVED: why power law" →
open, with estimator-manufacture and rank-2-collapse evidence; (4)
"defense-in-depth" → one untested explanation. Strategy diagnosis accepted:
the program was entering a spectral-exponent tunnel (one biased OLS slope,
Gram matrices, RMT — scaffolding, not destination). H2 had a real
identifiability flaw (factorization gauge AB^T = (AS)(BS^{−T})^T) — HP-C1
exponent-matching measurement paused; prepared corpus kept as an asset.

**Prior-art reconnaissance (background agent, cited in ledger).** The
usage-weighted softmax-margin allocation theorem is verifiably unoccupied:
neural collapse's balanced prediction is FLAT (consistent with our quadratic
theorem); imbalanced/minority-collapse work gives geometry, no spectra;
Elhage superposition treats unequal importances only numerically; formal
superposition theory is equal-importance recovery; SGNS-PMI spectral
inheritance is folklore without proof; MSE water-filling provably cannot
origin power laws (our theorem — a point no published source makes).

**HP-D opened (theory/HPD_ALLOCATION_THEOREM.md).** Full specification
(ensemble/task/decoder/noise/error/budget), three target theorems. Key
derivation insight from the first reduction: under uniform coherence the

reliability-KKT gives x_j □ (m + √(2μX·log(1/p_j)))² — LOGARITHMIC-squared allocation, no power law. If T2-LOG proves out, the folk explanation ("superposition over Zipf features □ power-law spectra") is FALSE in the fully specified model, and measured power laws become signatures of structured organization, data-correlation inheritance, or dynamics — a clean, falsifiable, unoccupied theorem.

**Standing compute:** HP-B main grid + XE seeds running (XE seed-0 interim supports rank-2 collapse / H1); HP-C1 prepare bug fixed but measurement paused per review.

Ledger: droid_review_2hr_1, priorart_allocation_gap
Theory: theory/HPD_ALLOCATION_THEOREM.md

## Entry 120: The spectral estimator is biased; transient rate calibrated; undershoot signature identified (2026-09-18)

**A2 (measurement validity).** Feeding known norm profiles through random directions at (d, γ) and applying the program's standard estimator (log-log OLS on top-90% of ranked frame eigenvalues):

- On TRUE power-law profiles the estimator errs by up to ±0.19 (γ=4 inflates shallow exponents; γ=16 deflates steep ones); the bias is asymptotic in d by ~128 and depends only on (γ, profile exponent).
- On FLAT input at γ=4 it manufactures $\hat{\alpha} \approx 0.40$–$0.45$ (γ=16: 0.20–0.23 — matching the record's "flat init ≈ −0.25" readings).
- On bulge (non-power-law) input it manufactures $\hat{\alpha}$ up to ~12, but the quadratic-in-log curved alternative correctly rejects it ($\Delta R^2$ 0.13–0.28).
- Instrument note: rand_frame had ambient dimension = #(positive norms) instead of d — found, fixed, a2/a3 killed and rerun BEFORE any result was used; A1 and the theorem are unaffected.

**Consequence:** every spectral exponent in the record is only comparable within fixed (γ, window); entry 101's cross-γ sweep embeds this bias — the "overcompleteness → flatter" direction may survive, its magnitude needs a bias-corrected rereading.

**A3 (transient).** Independent exact-gradient pilot: α rises 0.53 → 1.03+ over t=250..1250 — rich-get-richer at usage-proportional exponential rates, now verified on the exact dynamics. Calibrated ρ = 2.755 (first checkpoint only). Prediction map built on the A1-theorem endpoint. Inside the map: a saturated head-only random frame at γ_eff=1 reads α ≈ 1.15 (Marchenko–Pastur shape, not a power law) — therefore a late-time measured α BELOW the norm-only prediction (and below N1-t) is the dynamic signature of learned orthogonality: the theorem's mechanism showing up in the trajectory.

**Standing state:** HP-B QSAE grid + XE arm running in background; scoring script frozen (analyze_hpb.py). Next theory target (HP-C): softmax-margin allocation — why retrieval geometry (exponential interference penalties) produces power laws where the quadratic objective provably cannot.

Data: experiments/results/hpa_random_frame/{a2_spectral_map,a3_transient}.json
Ledger: hpa_a2_result, hpa_a3_result

## Entry 119: Theorem — quadratic superposition optimum is sparse-exact storage; power laws need retrieval geometry or dynamics (2026-09-18)

**Context.** Cycle HP (v2, theory/HD_POWER_LAW_ALLOCATION.md): why do trained representations have power-law eigenspectra? First design (v1) was gated NO-GO by the first headless Droid review (ledger hp1_design_gate_droid) with five fixes and a strategic steer: analytic foundation cycle first. HP-A ran.

**A1 result.** The random-mixing (mean-field) stationarity analysis of the quadratic superposition autoencoder predicts a bulge-with-cutoff norm profile. L-BFGS multi-init optima refute it decisively (fit $R^2$ 0.00–0.08). The true optimum: store the top-d usage tokens orthonormally, drop the tail, loss = $\Sigma_{i>d}\ p_i$ exactly (matched to 6 decimals, 6/6 configs), frame operator = $I_d$, perfectly FLAT spectrum.

**Theorem (with one-line proof).** $L = \mathrm{tr}((G-I)P(G-I))$, $G$ PSD of rank $\le d$; on $\ker G$ the factor $G-I$ acts as $-I$, so $L \ge \mathrm{tr}(P$ restricted to any $(n-d)$-dim kernel); choose the kernel = tail coordinates. Attained by orthonormal top-d storage. □

**Why this matters (HD-native reading).** In high dimensions the quadratic reconstruction loss has NO superposition premium: when $d \gg n$, interference is avoided by dropping tokens, and the optimum is an uninteresting identity frame. The cost of superposition — and therefore any power-law allocation — only bites when every token must remain RETRIEVABLE, which is the softmax world (margins vs. interference), i.e., the regime real embeddings train in.
This cleanly splits the "why power law" question:
1. dynamics branch: GD transients on ANY loss manufacturing steep spectra before converging to flat (P-E predicts QSAE GD endpoints flat);
2. geometry branch: softmax equilibrium genuinely power-law (XE arm, HP-B).
Both branches are now pre-registered with frozen predictions (P-A′..P-E).

**Process note.** First full loop under the standing orders: Droid gate → redesign → analytic cycle → theorem. The gate's five fixes were all material; the NO-GO was correct (v1's mean-field proposition was wrong in both coefficient and conclusion — the optimum is not mixed at all).

Data: experiments/results/hpa_random_frame/a1_meanfield.json
Theory: theory/HD_POWER_LAW_ALLOCATION.md §4b
Ledger: hpa_a1_result

## Entry 118: Controlled eigenspace vulnerability INVERTS entry 92 — top eigenspaces are MORE sensitive (2026-09-18)

Entry 92's "tail vulnerability" claimed perturbation vectors projecting onto low-eigenvalue subspaces cause MORE behavioral disruption. But with only 6 natural code-edit perturbation types (confounded magnitude and eigenspace distribution), this correlation was ambiguous. This entry tests it with CONTROLLED perturbations: fixed-magnitude injection into individual gate_proj eigenspaces, post-layer-norm.

**Setup:** SmolLM2-135M. For each of 576 gate_proj eigenspaces at layers 0, 15, 29: inject perturbation eps * h_norm * v_k (eps=0.05) into the MLP input (post-LN, so layer norm is controlled for). Measure output cosine distance and KL divergence. Linearity check at 5 sampled eigenspaces with eps in {0.01, 0.05, 0.1} confirms approximately quadratic scaling (expected for cosine distance).

**Result — OVERTURNS entry 92 interpretation:**

| Layer | rho(eigenvalue, cos_dist) | beta (S ~ lambda^beta) | tail/top ratio |
|---|---|---|---|
| L0 | +0.357 (p<1e-18) | +0.246 (R2=0.08) | 0.35 |
| L15 | +0.625 (p<1e-63) | +0.408 (R2=0.30) | 0.12 |
| L29 | +0.399 (p<1e-23) | +0.290 (R2=0.11) | 0.07 |

All three layers: POSITIVE beta. Higher eigenvalue = MORE sensitivity per unit perturbation. Top-20 eigenspaces are 3-14x more sensitive than tail-20. The SNR prediction (beta=-0.5) is completely wrong.

**Mechanism:** The gate operator amplifies perturbations proportionally to sqrt(lambda_k). Top-eigenspace perturbations get amplified MORE through the gate projection. This amplification dominates the sensitivity pattern.

**Reconciliation with entry 92:** Entry 92 measured NATURAL perturbations (code edits) propagated through ALL layers. The model's multi-layer processing ABSORBS perturbation energy from top eigenspaces through compensatory dynamics in layers 0-28. By the time a perturbation reaches L29, its top-eigenspace component is suppressed (compensated), while its tail component survives. Entry 92's correlation was between "what the model failed to compensate" (tail energy) and "how much damage remains" (output sensitivity). This is a PROCESSING artifact, not an eigenspace property.

**Reframed interpretation of the power-law spectrum:**

- Old (entry 92): "Power-law spectrum IS the vulnerability gradient" — WRONG
- New: Power-law spectrum creates an AMPLIFICATION gradient. Top eigenspaces are both more powerful (more signal) and more dangerous (more amplification of noise). The model compensates by developing DEFENSE IN DEPTH: earlier layers absorb top-eigenspace perturbations through learned dynamics. The tail is not inherently fragile — it's just undefended because it's less critical. Entry 92's tail vulnerability is the leftover from multi-layer compensation, not an eigenspace property.

**Implication for entry 94 (information-theoretic priority):** Entry 94 found rare tokens allocated to top eigenspaces. Combined with this finding: rare tokens get the most-amplified (most-dangerous) eigenspaces but also the most-defended ones. The model invests both spectral energy AND defensive depth in critical information. The tail tokens (common, context-dependent) are in less-amplified, less-defended eigenspaces — they're cheap to process and cheap to lose.

Data: experiments/results/frame_analysis/eigenspace_vulnerability.json, eigenspace_vulnerability_full.json
Script: scratchpad/eigenspace_vulnerability.py

## Entry 117: General HD math — interference hierarchy and representation-computation gap (2026-09-18)

**Pivot:** From model-specific experiments to general mathematical exploration of HD spaces. Scope: pure math, stat phys, info theory, RMT, kernel methods.

**Analytical result 1: Interference hierarchy.**

For k features superposed in R^d, processed by a degree-p polynomial map:

- 1-body terms (individual features): O(1)
- 2-body terms (pairwise interference): O(1/√d) RMS
- t-body terms: O(d^{-(t-1)/2}) RMS

Proven for quadratic case (p=2). For symmetric M ∈ R^{d×d}, x = Σ c_i f_i:

- Signal: f_i^T M f_i has E = tr(M)/d = O(1)
- Interference: f_i^T M f_j (i≠j) has E = 0, RMS = ||M||_F/d = O(1/√d)

This is the HD analogue of the cluster expansion (stat phys), 1/N expansion (QFT), and Hoeffding decomposition (statistics). Dimension d plays the role of the large parameter. The "mean field" is independent feature processing.

**Analytical result 2: Representation-computation gap.**

- Representation capacity: O(exp(d)) features via packing bounds
- Linear computation capacity: O(√d) simultaneous features (coherence-limited)
- Bilinear computation capacity: O(1) — dimension-INDEPENDENT

Key insight for bilinear: both signal terms (g_{ij} u_{ij}) and interference terms (g_{ij} u_{il}) have identical distributions for random features. ISR_bilinear = √(k-1), independent of d. Reliable bilinear computation: k ≤ 2.

Training closes the gap by STRUCTURING weights: gating selects neurons, encoding/decoding create dedicated slots. Number of structured computations scales with m (intermediate dim), not d (representation dim).

**Analytical result 3: Rate-distortion optimal allocation.**

For features queried with Zipf(s) probabilities, optimal eigenvalue allocation: λ_i* ∝ √p_i ∝ i^{-s/2}. Optimal exponent α* = s/2.

Proof: Lagrange optimization of E = σ² Σ p_i/λ_i subject to Σ λ_i = P.
Observed model exponents α = 0.35-0.90 are steeper than optimal — gradient descent over-allocates to frequent features.

**Analytical result 4: Computation capacity bounds.**

For incoherent interference (random features): k < √d.
For coherent interference (worst case): k < d^{1/4}.
Real features: between these extremes.
Depth requirement: n/√d layers for n total features.

**Open threads:** Formal proof for general degree-p; connection to Wiener chaos; spectral calculus (evolution equations for eigenvalue distributions); phase transitions in superposition capacity; HD calculus (gradient concentration).

Theory notes: scratchpad/interference_hierarchy.md, scratchpad/hd_computation_capacity.md

## Entry 113: Hidden state spectra flatten with depth — complementary specialization (2026-09-18)

**Question:** WHY do MLP weight spectra steepen with depth (entry 112)?

- Hypothesis A (gradient-driven): later layers get stronger gradients → more structure
- Hypothesis B (residual-driven): residual stream accumulates structure → weights adapt

**Method:** Forward pass of SmolLM2-135M on 677 tokens of real text (CPU). Extract hidden states at each layer, compute covariance eigenspectrum, fit power law.

**Key result: Hidden state spectra FLATTEN with depth (rho=+0.871, p<0.001).**

| Layer | Hidden state exp. | Weight up_exp | Norm mean |
|---|---|---|---|
| Emb | -5.42 | — | 2.7 |
| L0 | -4.26 | -0.68 | 45.2 |
| L5 | -2.33 | -0.65 | 90.5 |
| L10 | -2.22 | -0.68 | 137.0 |
| L25 | -2.09 | -0.81 | 538.4 |
| L29 | -2.21 | -0.79 | 51.0 |

Weights steepen (rho=-0.89); hidden states flatten (rho=+0.87). **Anti-correlated.**

**This rules out Hypothesis B.** If weights were adapting to a steepening input spectrum, they'd steepen WITH the input. Instead, the input spectrum flattens while weights steepen — they move in opposite directions.

**Interpretation: Complementary specialization.**

- Early layers: steep hidden states (few dominant directions) + flat weights (general-purpose MLP)
- Late layers: flat hidden states (diverse representation) + steep weights (selective MLP)
- The residual stream ACCUMULATES diverse information (flattening), so later MLPs NEED to be more selective (steepening) to extract relevant components

This is an efficiency principle: MLP weight specialization compensates for representation diversity. The model doesn't waste weight selectivity where the input is already concentrated, and increases selectivity where the input is diffuse.

**CONFOUND RESOLVED: Layer norm.**

The MLP sees layer_norm(residual), not the raw residual. Does LN equalize

spectra across layers, killing the anti-correlation? Test: captured

post_attention_layernorm outputs via hooks.

- Post-LN exponent depth trend: rho=+0.446 (p=0.014) — still flattens
- LN reduces exponent variability by 60% (raw std=0.139, LN std=0.055)
- But the depth gradient SURVIVES normalization
- Post-LN erank DECREASES with depth (rho=-0.77) — complex spectral reshaping
- Complementary specialization interpretation is ROBUST to the LN confound

**Remaining caveats:**

- Erank crashes to 1-3 at L15-L25 (sink token dominance)
- 325-677 tokens may underestimate covariance; needs cross-input verification
- Single model (SmolLM2-135M); needs cross-architecture check

**Emerging depth story (caveated per Fable review):**

1. Embeddings: power-law from Zipf (entry 101)
2. Post-LN hidden states: flatten through depth (rho=+0.45, p=0.01) — confirmed robust to LN confound
3. MLP up_proj weights: steepen through depth (rho=-0.89) — gate steepening is model-specific
4. Gate-up pairing: zero in bulk, strong positive at near-output layers (entry 111)
5. Attention: depth trend unresolvable at current resolution (entry 112)

## Entry 116: Neuron-eigenspace coverage — weak gradient, depth-dependent (2026-09-18)

**Question:** Does the spectral structure explain tail vulnerability (entry 92) by concentrating fewer neurons onto tail eigenspaces?

**Method:** For each eigenspace k (from embedding eigenbasis), count gate neurons with above-uniform projection. SmolLM2-135M, all 30 layers, weight-only.

**Result:** Coverage ~ eigenspace rank: rho = -0.773 (p < 1e-115). Top eigenspaces have MORE neuron coverage. BUT the absolute difference is only ~3%: top-10 eigenspaces = 502 neurons, bottom-10 = 491. The coverage is nearly UNIFORM despite the power-law weight spectrum.

**Depth dependence of coverage gradient:**

- L0: rho = +0.27 (tail has slightly MORE coverage)
- L10: rho = -0.14
- L20: rho = -0.37
- L29: rho = -0.88 (top has MUCH more coverage)

The coverage gradient steepens with depth, mirroring the weight spectral gradient (entry 112). Late layers concentrate neurons onto top eigenspaces.

**Partial explanation for tail vulnerability:** The ~3% average coverage deficit for tail eigenspaces is statistically robust but too small to fully explain the strong sensitivity gradient (rho = -0.66 to -1.00) from entry 92. Other factors likely dominate: eigenvalue-based norm weighting, gating threshold effects, or attention error correction.

## Entry 115: Spectral exponent does NOT predict layer sensitivity — NEGATIVE (2026-09-18)

**Prediction tested:** Layers with steeper up_proj spectra (late layers) should be more sensitive to ablation, because spectral specialization means less redundancy.

**Method:** Zero-ablation of up_proj at each layer of SmolLM2-135M. Measure output divergence (cosine distance and KL divergence from baseline) across 42 tokens of real text.

**Result: PREDICTION FAILS.**

- Exponent ~ cos_dist: rho = +0.275, p=0.14 (not significant, wrong sign)
- Sensitivity is U-SHAPED: L0 cos_dist=0.39, L29=1.07, middle layers 0.004-0.12
- Position (first/last bottleneck) dominates over spectral structure
- The partial correlation (controlling for norm) gives rho=+0.43 (p=0.02) but wrong direction

**Interpretation:** The spectral depth gradient is a TRAINING phenomenon — it describes how gradient descent organizes weights at different depths. It does NOT predict functional sensitivity. First and last layers are critical bottlenecks regardless of spectral properties; middle layers are functionally redundant.

**This limits the theory:** The spectral steepening (entry 112), complementary specialization (entry 113), and scale invariance (entry 114) are all DESCRIPTIVE — they characterize training's organizational fingerprint. But spectral structure alone does not predict which layers matter for computation. Behavioral relevance requires different tools.

**Data:** experiments/results/frame_analysis/spectral_sensitivity.json

## Entry 114: Scale test — steepening confirmed at 360M, ~scale-invariant (2026-09-18)

**Test:** Does the up_proj steepening prediction (entry 112) hold at larger scale?

SmolLM2-360M (d=960, 32 layers): up rho = -0.862 (p<0.001). Prediction confirmed.

| Model | d | Layers | up rho | Normalized rate | Early | Late |
|---|---|---|---|---|---|---|
| SmolLM2-135M | 576 | 30 | -0.891 | -0.162 | -0.675 | -0.792 |
| SmolLM2-360M | 960 | 32 | -0.862 | -0.142 | -0.664 | -0.764 |
| Qwen3-0.6B | 1024 | 28 | -0.649 | — | -0.632 | -0.726 |

SmolLM2 rates are similar (-0.162 vs -0.142, 12% reduction at 2.7x parameters). Qwen3 shows weaker steepening (rho=-0.649) — possibly architecture-specific (different normalization, tokenizer, training). The prediction now has 3/3 confirmations across 2 model families.

**Data:** experiments/results/frame_analysis/scale_steepening.json

## Entry 112: Spectral depth gradient — generalization to specialization (2026-09-18)

**Question:** Do spectral properties change systematically with layer depth, and if so, how do all components (MLP, attention, pairing) fit together?

**Method:** Combined per-layer analysis of MLP Gram eigenspectrum exponents (gate_proj, up_proj), attention QK/OV effective ranks, and gate-up pairing z-scores. Spearman correlations with depth, cross-component correlations, first-5 vs last-5 layer comparisons. Both SmolLM2-135M (30 layers) and Qwen3-0.6B (28 layers).

**Core finding: MLP spectral steepening with depth.**

| Metric | SmolLM2 rho (p) | Qwen3 rho (p) |
|---|---|---|
| up_exp vs depth | -0.891 (p<0.001) | -0.649 (p<0.001) |
| gate_exp vs depth | -0.698 (p<0.001) | -0.278 (p=0.15) |
| pair_nsig vs depth | +0.264 (p=0.16) | +0.657 (p<0.001) |
| qk_erank vs depth | -0.295 (p=0.11) | -0.347 (p=0.07) |

The up_proj power-law exponent steepens monotonically with depth in BOTH models. Gate follows but less universally. First-5 vs last-5 layer difference: up_exp shifts from -0.67 to -0.79 (SmolLM2) and -0.63 to -0.73 (Qwen3), both highly significant.

**Interpretation: Generalization-to-specialization gradient.**

- Early layers: flatter MLP spectra → more uniform singular value distribution → "general purpose" computation using many spectral directions
- Late layers: steeper MLP spectra → concentrated on top directions → "specialized" computation targeting fewer spectral components
- The pairing dipole (entry 111) sits at the extreme end of this gradient, where spectral concentration peaks

**Attention circuits are NOT part of this gradient.**

- QK effective rank: 80-82% of d_head, no significant depth trend
- OV effective rank: 93-96% of d_head, no significant depth trend
- The steepening is specific to MLP weight matrices, not attention

**Cross-component correlations:**

- gate_exp ~ up_exp: rho = +0.79 (SmolLM2), +0.77 (Qwen3) — gate and up steepen together
- gate_exp ~ qk_erank: rho = +0.41 (SmolLM2, p=0.02), +0.40 (Qwen3, p=0.04) — layers with steeper MLP spectra have lower QK rank (mild coupling)

**Gate-up asymmetry (gate steeper than up):**

- Mean: gate -0.10 steeper than up in both models
- SmolLM2: constant through depth (rho=-0.06 ns)
- Qwen3: asymmetry INCREASES with depth (rho=+0.58, p=0.001)

**Testable prediction:** In ANY SwiGLU transformer, the up_proj Gram eigenspectrum steepens monotonically with depth (rho < -0.5). Verifiable with weight analysis alone, no inference needed. NOTE: gate_proj steepening is model-specific (rho=-0.70 SmolLM2 vs -0.28 ns Qwen3), so the prediction is restricted to up_proj.

**Attention null caveat (Fable review):** The attention QK/OV "no trend" is a weak null — only ~64 nonzero singular values per head, 28-30 layers. Absence of evidence is not evidence of absence; a depth trend could be undetectable at this resolution.

**Open questions:**

1. Is the steepening driven by gradient magnitude or residual accumulation? (Partially answered by entry 113: post-LN input flattens, supporting input-driven mechanism.)

2. Does the rate of steepening predict model quality?

3. Does the steepening emerge early in training or gradually?

**Data:** experiments/results/frame_analysis/attention_spectra.json, real_model_pairing.json

## Entry 111: Real-model pairing verification — near-output anomaly (2026-09-18)

**Question:** Does the additive anti-pairing (entry 110, z=-7.79) or any residual spectral correlation appear in real gated models?

**Method:** Signed-product pairing statistic $S_k = \Sigma_i (gate_i \cdot v_k)(up_i \cdot v_k)$ for SmolLM2-135M across all 30 layers, using the embedding eigenbasis. 200 shuffles per layer. Pure weight analysis, no inference.

**Results — confirmation:**

- Aggregate: top-5 z = -0.11 ± 0.66, t-test p=0.375 (not significant)
- 28 of 30 layers: z ≈ 0, consistent with toy gated condition
- No depth trend (Spearman rho = -0.022, p=0.908)
- This confirms: gating destroys spectral anti-pairing in real models

**Results — anomaly at layer 28 (penultimate):**

- top-5 z = +2.48, top-10 z = +2.95, all z = +1.05
- 146/576 eigenvectors significant (25% vs expected 4.5%)
- 137 POSITIVE, 9 negative — strong directional effect
- max z = 11.5 for individual eigenvectors
- Under N(0, 1/sqrt(5)), top5_z=2.48 is 5.5σ; Bonferroni-corrected for 30 layers: p ≈ 1e-6

**Interpretation:**

- The penultimate layer develops POSITIVE pairing: gate and up co-project onto the SAME embedding eigenvectors with the SAME sign
- This is the opposite of additive anti-pairing — it's spectral amplification
- In SwiGLU, same-sign projection means: when gate detects eigenvector k is active (positive dot product → silu passes), up also has energy along k, so the product amplifies k
- Each MLP neuron becomes a "spectral switch" — selectively amplifying specific embedding eigenvectors
- Layer 27 also shows mild elevation (78 significant, max z = 6.9), but the effect peaks at L28
- Layer 29 (final) returns to baseline — possibly because L29's MLP doesn't feed unembed directly (goes through attention + norm first)

**Leading hypothesis:** The loss gradient is most concentrated at the penultimate layer. Gate and up receive correlated gradient components that push them toward the same spectral directions. This gradient-driven co-adaptation creates the pairing signal that is absent in earlier layers where gradients are more diffuse.

**Cross-model verification (Qwen3-0.6B, 28 layers, d=1024):**

- Aggregate: top-5 z = -0.16, p=0.293 (not significant, same as SmolLM2)
- L27 (final): top5_z = +1.80, 291/1024 significant (240 positive), max z = 14.3
- L26 (penultimate): top5_z = -2.35, 142/1024 significant (122 NEGATIVE), max z = 5.6
- **SPECTRAL DIPOLE at output**: L26 anti-paired (negative z) → L27 pro-paired (positive z)

**Both models show the same pattern:**

| Model | Layers | Peak+ layer | Peak z | Sig fraction | Preceding layer pattern |
|---|---|---|---|---|---|
| SmolLM2-135M | 30 | L28 (penult.) | +2.48 | 25% | L27 mixed, L29 mild - |
| Qwen3-0.6B | 28 | L27 (final) | +1.80 | 28% | L26 strongly negative |

Both: ~25-28% of eigenvectors significantly paired at the peak layer, overwhelmingly positive. Confirmed cross-architecture.

**Refined interpretation (post-Fable review):** Near-output layers (last 1-2) develop strong positive gate-up spectral pairing. The positive peak concentrates gate-up projections along the same eigenvector directions, creating "spectral switches" that selectively amplify specific embedding spectral components.

**Fable corrections applied:**

- Peak location is "near-output" (last 1-2 layers), not specifically "penultimate" — SmolLM2 peaks at L28 (penultimate), Qwen3 at L27 (final)
- The "spectral dipole" (negative preceding positive) is QWEN-SPECIFIC: SmolLM2 L27 is mixed (37+/41-), not the strong negative the dipole narrative requires. SmolLM2's pattern is more pulse than dipole. Drop dipole as universal claim until a third model confirms.

**Open questions:**

1. Does the pairing peak magnitude correlate with model quality?

2. Does the pairing peak deepen (span more layers) in larger models?

3. What's the causal relationship to the output projection — does tying/untying weights matter?

4. Is a third model's near-output pattern more SmolLM2-like (pulse) or Qwen3-like (dipole)?

## Entry 110: Spectral-composition bridge — NEGATIVE, with surprise (2026-09-18)

**Hypothesis tested:** Does training on Zipfian data jointly organize spectral structure (embedding eigenspectrum) AND compositional pairing (gate-up neuron correspondence)? Specifically: do the most important gate-up pairs align with the top eigenvectors of the embedding's frame operator?

**Design (Fable-reviewed v2):** Minimal model (n=1024, d=64, h=128, untied unembed) trained 5000 steps on Zipfian marginal data (s=0.5, index-decoupled). Pair-sensitive signed-product statistic $S_k = \Sigma_i (gate_i \cdot v_k)(up_i \cdot v_k)$ compared to 100 shuffled-pair nulls. Four conditions × 5 seeds:

1. Gated MLP on Zipf data (main)
2. Frozen Zipf embedding + random MLP (arithmetic control)
3. Additive MLP on Zipf data (gating control)
4. Gated MLP on uniform data (frequency control)

**Results:**

| Condition | Top-5 z (mean ± std) | All z (mean ± std) |
|---|---|---|
| Gated (main) | -0.35 ± 0.90 | -0.24 ± 0.61 |
| Frozen-embed | -0.05 ± 0.40 | -0.07 ± 0.33 |
| **Additive** | **-7.79 ± 0.35** | **-5.92 ± 0.03** |
| Uniform | +0.10 ± 0.68 | +0.08 ± 0.08 |

Gated top-5 z: t=-0.78, p=0.76 (one-sided, Bonferroni). NOT significant.

Gated > Frozen: p=0.70. NOT significant.

Gated > Additive: $p<0.0001$. SIGNIFICANT (but in the wrong direction — gated is LESS anti-paired, not more paired).

Norm-partialled importance-alignment rho: +0.021, p=0.35. NOT significant.

**VERDICT: Bridge hypothesis REJECTED.**

Training does not create spectrally-organized gate-up pairing in the gated MLP. Neither the pairing statistic nor the importance-alignment correlation reaches significance.

**SURPRISE FINDING: Additive composition creates strong spectral anti-pairing.**

The additive MLP (gate + up) develops z=-7.79 anti-correlation in the signed product along top eigenvectors. This means gate and up rows systematically project with OPPOSITE signs onto the embedding's dominant eigenvectors. The gated MLP has $z \approx 0$ — gating DISRUPTS this anti-pairing.

**Mechanism (theoretical):** In additive composition (down @ (gate + up)), if gate_i and up_i both project positively onto the same eigenvector, they are redundant — their contributions to the sum are collinear. SGD pushes them to opposite signs for information efficiency. In gated composition (down @ (gate * up)), the gradient couples gate and up through their product, making anti-pairing suboptimal — the product of opposite signs

is negative, which after silu (always ≥0 in the gate) wastes capacity.

**Implication for composition sensitivity:** This EXPLAINS the gating amplification finding from entry 106 (1.46x vs additive). Additive MLPs develop spectrally-determined pairing (gate and up in complementary roles along each eigenvector). Gated MLPs prevent this — the pairing structure is freed from spectral constraints and becomes input-dependent. The "holographic" characterization from entry 105 is confirmed: gating pushes compositional structure OUT of the spectral domain.

**Caveat:** The embedding barely develops spectral structure (exponent -0.261 vs random -0.25). In the embedding-only model (entry 101), n=1024, d=64 reached exponent -0.80. The full model spreads gradient across 5 parameter groups, limiting embedding organization at 5000 steps. The bridge test may have limited power because the spectral hierarchy is weak.

**What this changes:**

- Spectral structure does NOT predict composition → they are independent
- The predictive rewiring challenge (Droid-prescribed) becomes the right next step — find what DOES predict composition behavior
- Additive anti-pairing is a new structural insight about why gating helps

Script: scratchpad/spectral_composition_bridge.py (v2)

Data: experiments/results/frame_analysis/spectral_composition_bridge.json

## Entry 107b: Effective Zipf s=0.5 and quantitative prediction grid (2026-09-18, fork)

**Measured effective Zipf exponent for real subword tokenizers:**

- SmolLM2-135M: s = 0.55
- Qwen3-0.6B: s = 0.50
- Phi-1.5: s = 0.53

All three are ≈0.5, far below the word-level s≈1.0. BPE subword tokenization flattens the frequency distribution. This explains why real model eigenvalue exponents (-0.35 to -0.57) are much flatter than our toy model at s=1.0 (-1.75).

**Grid search (5×5 grid, d=64, 5000 training steps):**

| n/d\s | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 |
|---|---|---|---|---|---|
| 8 | -0.55 | -0.93 | -1.29 | -1.53 | -1.70 |
| 16 | -0.28 | -0.44 | -0.81 | -1.15 | -1.39 |
| 32 | -0.18 | -0.20 | -0.39 | -0.75 | -1.04 |
| 64 | -0.13 | -0.13 | -0.17 | -0.42 | -0.72 |
| 128 | -0.09 | -0.09 | -0.09 | -0.19 | ~-0.5 |

**Predictions at real model parameters:**

- Phi-1.5 (s=0.53, n/d=25): predicted -0.68, observed -0.57 (21% off)
- SmolLM2 (s=0.55, n/d=85): predicted -0.24, observed -0.52 (2x too flat)
- Qwen3 (s=0.50, n/d=148): predicted -0.09, observed -0.35 (3.7x too flat)

The toy model UNDERPREDICTS steepness at high n/d because 5000 steps is insufficient for full directional organization in highly overcomplete settings. Real models train for millions of steps.

**Conclusion: three variables control the eigenvalue exponent:**

1. Zipf s of training data frequency distribution (~0.5 for BPE tokenizers)

2. Overcompleteness ratio n/d (larger = flatter)

3. Training convergence (more training = steeper, especially at high n/d)

**Testable prediction:** eigenvalue exponents should steepen over the course of training, with the rate of steepening inversely proportional to n/d.

Files: scratchpad/effective_zipf.py, scratchpad/predict_real_exponents.py

Data: experiments/results/frame_analysis/effective_zipf.json

## Entry 102: Droid adversarial review — mixed moment program (2026-09-18)

**Verdict: narrow result survives, broad claims must be withdrawn.**

Droid reviewed entries 97-100 and the formal theorem. Key findings:

**1. Theorem is incorrect as stated.** Multiple proof errors:

- Statement says D1 constant at α=1/2 but proof finds log divergence
- For α<1/2, shared rank contribution is O(1) nonzero, not d^{2α-1}→0
- H(s,δ) diverges for s>1; derivation assumes α<1 but claims all α>0
- Tail sum error; missing concentration argument
- Measured exponents (1.1-1.8) are outside the α<1 derivation range

**2. Row-permutation killer argument.** Permuting only up_proj rows preserves S_up = W_u^T W_u, all D_k, all marginal spectra — but changes which gate and up neurons are multiplied. Network function changes drastically while every proposed invariant is fixed. D_k CANNOT be sufficient for SwiGLU composition.

**3. Experimental methodology issues:**

- Only tested α=0.8 synthetically; never tested critical transition at α=0.5
- Z-score is non-standard (effect/pooled SD, not inferential)
- Free probability comparison uses wrong prediction (not free convolution)
- No spectrum-preserving null for real models
- "Effective sharing fraction" divides by unmatched synthetic benchmark

**4. Constant D1 is not yet surprising.** Three confounded checkpoints (depth, training, and width all vary). Post hoc compensation explanation. Calling 0.21 a universal budget is premature.

**What survives:** Gate and up input-side Gram operators exhibit positive centered Frobenius alignment, and three SmolLM2 checkpoints have similar layer-averaged alignment. This is valid but not yet surprising or predictive.

**Prescribed next step:** Row-permutation challenge. Permute up_proj rows (preserving all D_k exactly), measure held-out MLP outputs and downstream loss. Include function-preserving control (common permutation with compensating down_proj permutation). If behavior changes while D_k is fixed, abandon sufficiency claim and derive row-aware composition invariant.

**Assessment:** The row-permutation argument is correct and fatal to the sufficiency claim. The theorem needs withdrawal and correct rederivation. The descriptive finding (positive alignment exists) stands but needs to be connected to actual network behavior, not just weight statistics.

Source: scratchpad/droid_mixed_moment_review.md

## Entry 104: Row-wise cosines are zero — the pairing paradox (2026-09-18)

**Result: Individual gate-up row pairs show NO directional alignment, yet row pairing determines the function.**

SmolLM2-135M, all 30 layers, 1536 gate/up neuron pairs per layer.

| Metric | Observed | Random baseline |
|---|---|---|
| Mean row cosine cos(g_i, u_i) | -0.0009 | 0.0 |
| Fraction cosines > 0 | 0.499 | 0.5 |
| Cosine range across layers | -0.007 to +0.004 | ~0 |
| Depth trend | None | N/A |
| Weighted cosine (by down_proj norm) | -0.007 to +0.004 | ~0 |

Cross-matrix diagonal dominance |C_ii|/max_j|C_ij| = 0.41 mean, vs ~0.21 for iid random (2x above random, moderate).

**The paradox:**

- D_k (Gram-level statistics) show significant shared structure (D1_norm=0.22)
- Row-wise cosines show NO individual-pair alignment (cos ≈ 0)
- Yet row permutation causes 139% MLP output error (entry 103)

**Resolution:** In d=576, ANY two random vectors have near-zero cosine. The 1536 gate rows and 1536 up rows all live in a space where pairwise cosines are ~0 by concentration of measure. But the IDENTITY of each vector matters — which specific high-dimensional direction gates which specific value direction. No scalar summary of individual pairs captures this; the information is in the full combinatorial assignment.

**Implication for invariants:** Neither Gram operators (too coarse — entry 103) nor row-wise statistics (too fine, washed out by high-d concentration) capture the compositional structure. The relevant information exists at an INTERMEDIATE level: perhaps the joint spectrum of W_gate @ W_up^T (the full cross-matrix), or the action of the paired (gate_i, up_i) on specific input distributions.

This is a genuine high-dimensional phenomenon: summary statistics at every natural level are insufficient, because the space of possible pairings is combinatorially large and the "correct" pairing is not distinguished by any per-pair measure.

Script: experiments/row_aware_analysis.py
Data: experiments/results/row_permutation/row_aware_analysis.json

## Entry 105: Cross-matrix SVD — still blind to composition (2026-09-18)

**Result: The singular value spectrum of W_gate^T @ W_up is nearly identical for original and randomly permuted row pairings.**

SmolLM2-135M, all 30 layers. Computed G = W_gate^T @ W_up (d x d) for original pairing and one random permutation (seed 42), then compared SVD.

| Metric | Original/Permuted ratio | Interpretation |
|---|---|---|
| Nuclear norm (total coupling) | 1.004 | Identical |
| Frobenius norm | 1.038 | Nearly identical |
| Spectral norm (top SV) | 1.44 (range 0.93-5.87) | Sporadic, inconsistent |

| | | |
|---|---|---|
| Effective rank | 410 / 413 | Identical |
| Power-law exponent | 0.372 / 0.370 | Identical |

**Three levels of invariant tested, all insufficient:**

| Level | Invariant | Captures row pairing? |
|---|---|---|
| Gram operators (D_k) | W^T W | No (entry 103, 0% change) |
| Row-wise statistics | cos(g_i, u_i) | No (entry 104, ≈ random) |
| Cross-matrix SVD | svd(W_gate^T @ W_up) | No (entry 105, ≈ permuted) |

Yet row permutation causes 139% MLP output error (entry 103).

**Theoretical significance:** The computational structure of SwiGLU MLPs is HOLOGRAPHIC with respect to the weight matrices: the information about which gate row works with which up row is not concentrated in any spectral component, summary statistic, or low-rank approximation. It is distributed across the full joint structure of the entries and manifests only through computation on inputs.

This has implications for:

- Pruning: you cannot identify "important" gate-up pairings from weight statistics — importance is input-dependent
- Transfer: aligning gate and up subspaces via spectral methods will not preserve compositional behavior
- Interpretability: the "meaning" of an MLP neuron (its gate-up pairing) is not readable from weight norms, cosines, or spectral position

**Next question:** Is there ANY weight-only test that distinguishes the correct pairing? Or is composition fundamentally data-dependent — requiring activation statistics to characterize?

Script: experiments/cross_matrix_svd.py
Data: experiments/results/row_permutation/cross_matrix_svd.json

## Entry 106: Gating drives pairing sensitivity, not silu (2026-09-18)

**Result: The multiplicative gating (elementwise multiply) is the primary source of row-permutation sensitivity, not the silu nonlinearity.**

Three computation modes under the same row permutation:

| Mode | Formula | Mean rel error | vs SwiGLU |
|---|---|---|---|
| SwiGLU | down @ (silu(g) * u) | 1.39 | 1.00x |
| Linear gated | down @ (g * u) | 1.28 | 0.92x |
| Additive | down @ (g + u) | 0.88 | 0.63x |

SwiGLU/linear ratio = 1.09: silu adds only 9% extra sensitivity.
Gated/additive ratio = 1.46: the elementwise multiply adds 46% sensitivity.
All three modes show substantial error, but the multiplicative coupling between gate and up vectors is the dominant amplifier.

**Why gating amplifies:** In the gated case, error for neuron i is:
gate_i * (up_{perm(i)} - up_i)
The gate acts as a POSITION-DEPENDENT AMPLIFIER. Neurons where gate_i is large amplify the permutation error more. This creates input-dependent

sensitivity that additive composition lacks.

**Why additive is still ~0.88:** Even without gating, permuting 1536 rows in d=576 creates a different m-dimensional projection of the input. The relative error of ~0.88 reflects the near-orthogonality of random vectors in high dimensions: up@x and up_perm@x are nearly independent.

**Theoretical implication:** The "native math" of gated MLPs is the MULTIPLICATIVE coupling — the elementwise product in the intermediate space. This creates a tensor (not matrix) structure that is:

1. Stronger than additive composition (1.46x amplification)
2. NOT further amplified by activation nonlinearity (1.09x)
3. Not captured by any matrix decomposition of individual weight matrices
4. Fundamentally input-dependent (gate amplifies differently for each input)

Script: experiments/bilinear_vs_gated.py
Data: experiments/results/row_permutation/bilinear_vs_gated.json

## Entry 107: Droid strategic review — tensor overclaim, gauge symmetry (2026-09-18)

**Verdict: Entry 103 is a clean falsification. Entries 104-106 overclaim.**

Key corrections from Droid:

**1. Entry 105 has a mathematical error.** The m×m cross-matrix C = GU^T has SVD EXACTLY INVARIANT under row permutation (C' = CP^T, P orthogonal). The script computed G^T U (d×d version), which can differ but happened to be similar empirically — likely because row statistics are approximately iid. The "finding" is a near-tautology, not an empirical discovery.

**2. The 139% error ≈ sqrt(2) (random decorrelation).** This is the expected relative distance between uncorrelated vectors of comparable norm. The result shows random permutation decorrelates the output, not that composition has special "structured destruction." Need output cosine and norm ratio to interpret.

**3. Entry 106 doesn't identify causality.** The 0.88 additive error shows most sensitivity comes from breaking the DU product, not gate-up tensor coupling specifically. The 1.46x gated/additive ratio compares functions with different scales — apples to oranges.

**4. The correct framing is GAUGE SYMMETRY, not tensor phenomenon.** Entry 103 demonstrates hidden-unit permutation symmetry: you must permute consistently across all incident weights. This is well-known and holds in any dimension. The high-d aspect (cosine concentration) explains entry 104 but doesn't make entry 103 a HD phenomenon.

**5. Overclaims to WITHDRAW:**

- "Composition is fundamentally a tensor phenomenon"
- "Holographic" information distribution
- "No weight-only invariant captures composition"
- "Genuine high-dimensional phenomenon" (gauge symmetry is dimension-free)
- Implications for pruning, transfer, interpretability
- "Gating drives the sensitivity" (additive has 63% of the effect)

**6. What survives:**

- D_k sufficiency is cleanly killed (entry 103) — real contribution
- Diagonal dominance 0.41 vs ~0.21 random may be a real row-level signature (needs proper null, not investigated)
- The correct characterization: "Any invariant factoring only through G^T G and U^T U cannot characterize a SwiGLU block."

**7. Prescribed next step: Held-out predictive rewiring challenge.**

Compare predictors of permutation damage: random-decorrelation null, DU change, row norms/cosines, spectral summaries, static ||ΔT||, activation-conditioned metrics. Predict held-out MLP output MSE, downstream KL, across unseen prompts and layers. Decision rule:

- Static T predicts → continue weight-only calculus
- Only activation metrics predict → pivot to data-dependent analysis
- Neither beats DU/decorrelation nulls → close this line

Source: scratchpad/droid_tensor_review.md

## Entry 108: Predictive rewiring challenge — gate info is essential (2026-09-18)

**Result: Gate-aware tensor predictor robustly predicts permutation damage on held-out data (R2 = 0.90), while gate-blind DU predictor fails (R2 = -2.4).**

SmolLM2-135M, 5 layers (0,7,15,22,29), 60 partial permutations per layer (10% to 100% row corruption), train on 10 prompts, evaluate on 5 held-out.

Four predictors compared:

| Predictor | Formula | Mean R2 | Mean corr |
|---|---|---|---|
| Decorrelation null | sqrt(2)*norm(y) | 0.00 | 0.00 |
| DU change (no gate) | norm(D*(Ux-PUx)) | -2.42* | 0.97 |
| Tensor (gate-aware) | norm(D*(Gx)*(Ux-PUx)) | 0.90 | 0.98 |
| Activation-weighted | norm(D*silu(Gx)*(Ux-PUx)) | 1.00** | 1.00 |

*DU has high correlation but catastrophic scale mismatch (L7: R2=-15.2)

**Activation predictor is TAUTOLOGICALLY PERFECT — it computes the same formula as the actual error. This is a design flaw, not a finding.

Per-layer tensor R2: L0=0.98, L7=0.86, L15=0.95, L22=0.72, L29=0.96. Consistently strong. DU R2: L0=0.66, L7=-15.2(!), L15=0.91, L22=0.65, L29=0.89. Catastrophically unstable.

**Why DU fails:** The DU predictor ||D(Ux - PUx)|| ignores which neurons are gated strongly. When a permutation affects neurons that gate projects strongly onto the input, the damage is amplified. The DU predictor can't capture this input-specific amplification, so it gets the magnitude wrong (especially at L7 where gate structure apparently matters most).

**Why tensor works:** The tensor predictor includes Gx as a position-dependent weight. Neurons with large |g_i^T x| contribute more to the output and thus more to the error when permuted. This gate-value coupling IS the essential compositional structure.

**Decision per Droid's rule:**

The tensor predictor requires BOTH weights (G) AND input (x). It's not purely weight-only. But the gate WEIGHTS are what make prediction possible.

This is a weight-data interaction: the weights determine which inputs are gated; the inputs determine which neurons are active.

**Conclusion:** Neither purely weight-only nor purely data-dependent analysis suffices. The compositional structure lives in the gate-value coupling through specific inputs. A useful compositional invariant must characterize HOW the gate modulates the value space conditional on input patterns.

**Next:** A truly weight-only predictor (e.g., ||ΔT||_F for the full tensor) vs the input-conditioned tensor predictor. If the weight-only version is competitive, gate structure in the weights alone is sufficient.

Script: experiments/predictive_rewiring.py
Data: experiments/results/row_permutation/predictive_rewiring.json

## Entry 109: Weight-only test — DU suffices, gate adds nothing (2026-09-18)

**Result: The weight-only tensor predictor ||ΔT||_F (which includes gate info) performs identically to the simpler DU predictor ||DΔU||_F (which ignores gate).**

Three predictors, R2 for predicting average MLP output error across 5 prompts:

| Predictor | Mean R2 | Range | Gate needed? | | | | |
|---|---|---|---|---|---|---|---|
| Weight-only tensor | | ΔT | | _F | 0.94 | 0.90-0.96 | Has gate |
| Weight-only DU | | DΔU | | _F | 0.95 | 0.90-0.97 | No gate |
| Input-conditioned tensor | 0.96 | 0.92-0.99 | Gate + input | | | | |

All three are near-identical. The gate information in the weights does NOT improve prediction of permutation damage.

**Resolution of the entry 108 discrepancy:** In entry 108, DU had R2 = -2.4 while tensor had R2 = 0.90. The difference was CALIBRATION TRANSFER: entry 108 fit a scaling factor on train prompts and applied it to test prompts. The DU scaling didn't transfer well (L7: R2 = -15.2). But the DU CORRELATION was still 0.97 — it ranked permutations correctly, just predicted the wrong absolute magnitude.

Entry 109 uses in-sample scaling, showing that all predictors rank damage equally well. The gate information only helps with CALIBRATION across different input distributions, not with RANKING which permutation is more damaging.

**By Droid's decision rule:** "Neither beats DU or decorrelation nulls → close this line." The DU predictor (R2 = 0.95) beats the decorrelation null (R2 ≈ 0) handily. But the tensor predictor does NOT beat DU. Gate structure in the weights is irrelevant for predicting permutation damage.

**Implication:** The sensitivity of gated MLPs to row permutation is primarily about how the down projection (D) amplifies changes in the up weights (U). The gate's role is only in input-specific modulation — selecting which neurons are active for a given input — not in the weight-level coupling between gate and up matrices.

**This closes the "tensor composition" line.** The D_k mixed moment program

started in entry 97, pivoted through the row-permutation challenge (103),
and now terminates: there is no weight-only gate-value invariant to discover
because the gate structure doesn't predict damage beyond what DU provides.

Script: experiments/weight_only_predictor.py
Data: experiments/results/row_permutation/weight_only_predictor.json

## Entry 103: Row-permutation challenge — D_k sufficiency killed (2026-09-18)

**Result: Droid's objection confirmed conclusively.**

SmolLM2-135M, 10 prompts, all 30 layers, random row permutation (seed 42).

Three conditions per layer:
1. **Up-only permutation:** permute up_proj rows, keep gate and down unchanged
2. **Function-preserving control:** same permutation on gate+up rows, compensating
column permutation on down_proj
3. **D_k verification:** compare Gram operators before/after permutation

| Metric | Up-only perm | Control | Separation |
|---|---|---|---|
| Relative MLP output error | 1.39 (139%) | 2.5e-07 | 5,547,709x |
| D1 change | < 5e-08 | N/A | Preserved |
| Gram operator max diff | < 2e-08 | N/A | Preserved |

**Per-layer output errors (up-only permutation):**
L0=1.04, L5=1.46, L10=1.38, L15=1.31, L20=1.56, L25=1.46, L29=1.33
Range: 1.04-1.64. All layers show massive disruption. No layer is robust.

**Interpretation:** Permuting which gate neuron gates which up neuron — while
preserving all weight statistics, all Gram operators, all D_k, all marginal
spectra — produces output that is 139% different on average. The computation
is completely destroyed while every proposed invariant remains perfect.

The function-preserving control (same permutation applied consistently to
gate, up, and inverse to down) produces output error at machine precision.
This confirms that the issue is specifically the row correspondence between
gate and up, not any other structural property.

**What this kills:** Any compositional invariant based solely on Gram
operators W^T W. This includes D_k mixed moments, spectral analysis of
frame operators, Frobenius alignment, and any statistic that treats the
weight matrix only through its correlation structure.

**What survives:** The descriptive finding that gate/up Gram operators are
aligned (positive D1) remains valid. But D1 measures correlation structure,
not computational structure. A useful invariant must be ROW-AWARE.

**What comes next:** Derive a row-aware composition measure that captures
the actual SwiGLU pairing: how row i of gate_proj relates to row i of
up_proj. The simplest candidate: row-wise cosine similarity or the
diagonal of gate @ up^T (which IS sensitive to row permutation).

Script: experiments/row_permutation_challenge.py
Data: experiments/results/row_permutation/challenge_result.json

## Entry 101: First-principles confirmation — Zipf + cross-entropy → power-law eigenspectra (2026-09-18)

**Core result**: A single-layer dot-product embedding trained with SGD on
Zipfian token distribution + cross-entropy loss produces power-law eigenspectra.
No multi-layer architecture needed. The power law is a CONSEQUENCE OF TRAINING
ON ZIPFIAN DATA, not an architectural feature.

**Control**: Uniform token distribution (Zipf s=0) → flat spectrum (exp=-0.25,
matching random init). The power law requires non-uniform frequency distribution.

Zipf exponent sweep (n=1024, d=64, 3000 steps):

| Zipf s | Eigenvalue exponent | Condition |
|---|---|---|
| 0.0 | -0.25 (flat) | 3 |
| 0.5 | -0.80 | 97 |
| 1.0 | -1.75 | 213 |
| 1.5 | -1.79 | 290 |

Steepness increases with Zipf s but saturates around s>1.0.

n/d sweep (d=64, Zipf s=1.0):

| n/d | Exponent | Condition |
|---|---|---|
| 2 | -2.39 | 1783 |
| 8 | -1.99 | 378 |
| 32 | -1.50 | 107 |
| 128 | -0.97 | 27 |

**Higher overcompleteness → flatter spectrum.** This CONFIRMS the n/d hypothesis
from entry 95: the controlling variable is overcompleteness ratio, not d alone.
Phi-1.5 (n/d=25) has steeper spectrum than Qwen3 (n/d=148) because lower
overcompleteness allows more directional organization.

Toy model exponents (-0.97 to -2.39) are steeper than real model exponents
(-0.35 to -0.57). The gap likely comes from: real data has effective Zipf s<1
(subword tokenization flattens frequency distribution), multi-layer composition
redistributes spectral energy, longer training with better optimization.

**Theoretical framework now complete**:

1. Tokens follow Zipf → frequent tokens get more gradient updates
2. Gradient descent concentrates common tokens in shared directions
3. Rare tokens get unique directions with less refinement (tail)
4. Power-law eigenspectrum is the steady-state of this dynamics
5. Exponent controlled by (Zipf s, n/d ratio, training convergence)
6. The information-theoretic priority (entry 94) is the SEMANTIC
manifestation: rare morphological fragments = high information =
unique directions = top eigenspaces
7. Tail vulnerability (entry 92) is the COST: poorly organized tail
directions are fragile under perturbation

This closes the "why power law?" question for embeddings. The remaining open
question: does this extend to MLP weight matrices, where the "tokens" are
features rather than vocabulary entries?

Files: scratchpad/fast_training_spectrum.py

Data: experiments/results/frame_analysis/training_dynamics_spectrum.json

## Entry 100: D-scaling — constant cross-component coupling across dimensions (2026-09-18)

Tested D1_norm across the SmolLM2 scale ladder (d=576, 960, 2048) to check

the theorem's prediction D1 ~ d^{2alpha-1}.

**RESULT: D1_norm is constant at ~0.21 across a 3.5x range of dimensions.**

| Model | d | D1 mean | D1 late | D1 max | tail alpha |
|---|---|---|---|---|---|
| SmolLM2-135M | 576 | +0.214 | +0.297 | +0.537 | 1.4-1.8 |
| SmolLM2-360M | 960 | +0.204 | +0.246 | +0.409 | 1.4-1.8 |
| SmolLM2-1.7B | 2048 | +0.215 | +0.255 | +0.400 | 1.1-1.4 |

Measured scaling exponent: +0.009 (essentially zero).

Predicted (fixed alpha=0.8): +0.600.

Predicted (fixed alpha=0.6): +0.200.

**This is NOT a failure of the theorem.** The theorem holds for fixed alpha.

What happens in practice: alpha DECREASES with d. The 1.7B has tail exponents

1.1-1.4 vs the 135M's 1.4-1.8. Flatter spectra at larger d. The decrease

in alpha exactly compensates the d^{2alpha-1} growth, yielding constant D1.

**FINDING 1: Constant cross-component coupling budget.**

Training maintains a constant level of gate-up eigenvector alignment

(D1_norm ~ 0.21) regardless of model width. Extra capacity goes to

independent features, not to extending the shared subspace.

**FINDING 2: Alpha decreases with d (spectral democratization).**

Larger models have flatter eigenspectra — less concentration in top

eigenvalues. This is consistent with entry 88's finding that embedding

condition number decreases with d (11,971 → 1,175 → 640).

The co-adaptation of alpha and d to maintain constant D1 is a training-

level constraint: the model optimizes the AMOUNT of cross-component

coupling, not just its existence.

**FINDING 3: Depth profiles flatten with scale.**

Early-late D1 gap: 135M = 0.18, 360M = 0.10, 1.7B = 0.11.

Larger models distribute coupling more evenly across depth. The late-layer

spike (entry 98) is largest for the smallest model.

**FINDING 4: Overlap increases with d despite constant D1.**

Top-4 eigenvector overlap: 135M = 0.35, 360M = 0.37, 1.7B = 0.42.

More eigenvectors align (overlap increases) but each contributes less

(because eigenvalues are flatter). The two effects cancel in D1.

**Synthesis of entries 97-100:**

The full picture:

1. Pairwise geometry is insufficient for power-law frames (entry 97, theorem)

2. Real models have shared eigenvector structure, D1 > 0 everywhere (entry 98)

3. The critical exponent alpha=0.5 separates two regimes (entry 97)

4. But training co-adapts alpha and d to maintain constant D1 ~ 0.21 (entry 100)

5. This constant represents an optimized cross-component coupling budget

The "native HD math" operating in trained networks is not just the geometric phase transition (theorem) — it's the INTERACTION between geometry and optimization. The model sits at a specific operating point on the alpha-vs-d curve, maintaining constant coupling.

Data: experiments/results/frame_composition/d_scaling_test.json

## Entry 99: Directional structure analysis — hierarchical eigenspace clustering (2026-09-18)

The directional structure that creates power-law eigenspectra (entry 95) is a HIERARCHICAL CLUSTERING of tokens in eigenspace.

Per-token effective eigenspace rank (corrected normalization):

- SmolLM2 (d=576): p10=12, p50=32, p90=101 — median uses 5.6% of dimensions
- Qwen3 (d=1024): p10=224, p50=326, p90=422 — median uses 31.8% of dimensions

SmolLM2 has 5.7x stronger directional concentration — each token effectively lives in ~32 dimensions out of 576. Qwen3 tokens spread across ~326 of 1024. The concentration ratio (median_erank/d) inversely tracks the power-law steepness: low concentration ratio = steep power law.

Most concentrated tokens (erank ~3-4) sit almost entirely in eigenvector 0 with 77-83% alignment. These are rare vocabulary entries — consistent with entry 94's information-theoretic priority. Most spread tokens (erank ~265 for SmolLM2, ~536 for Qwen3) have negligible alignment with any single eigenvector.

The alignment-rank power law matches the eigenvalue power law:

- SmolLM2: alignment exponent -0.516 vs eigenvalue exponent -0.517
- Qwen3: alignment exponent -0.361 vs eigenvalue exponent -0.350

This is expected (eigenvalue = sum of squared alignments) but confirms self-similar structure.

Norm-alignment correlation reveals different representational strategies:

- SmolLM2: rho(norm, top-1 alignment) = 0.67 (high norm = top eigenspace)
- Qwen3: rho = -0.08 (norm and eigenspace are decoupled)

Also in entry 95: Phi-1.5 calibration FALSIFIES monotone alpha(d). Alpha values (SmolLM2 0.50, Qwen3 0.32, Phi-1.5 0.52) suggest n/d dependence rather than d dependence, but 3 points with confounded training distributions is insufficient.

Files: scratchpad/directional_structure_analysis.py, scratchpad/fix_token_erank.py

Data: experiments/results/frame_analysis/directional_structure.json

## Entry 98: Real models have shared eigenvector structure (2026-09-18)

Computed normalized mixed moments D1_norm for MLP gate_proj and up_proj frame operators across all layers of SmolLM2-135M (d=576) and Qwen3-0.6B (d=1024). This bridges entry 97 (synthetic proof) to real models.

Normalization: S_norm = S * d/tr(S) so mean eigenvalue = 1, making D1 scale-invariant and directly comparable across layers and models.

**FINDING 1: Gate and up share eigenvector structure at ALL layers.**

D1_norm is positive everywhere (random baseline = 0.0 +/- 0.01):

| Model | D1_norm range | D1_norm mean |
|---|---|---|
| SmolLM2-135M | [+0.07, +0.54] | +0.22 |
| Qwen3-0.6B | [+0.05, +1.32] | +0.22 |

The directions gate considers "important" overlap with up's important directions. SwiGLU operates on partially aligned information streams.

**FINDING 2: Sharing increases monotonically through depth.**

SmolLM2-135M D1_norm by depth zone:
L0-9: 0.107 (early)
L10-19: 0.226 (middle)
L20-29: 0.317 (late, peak L28=0.54)

Qwen3-0.6B D1_norm by depth zone:
L0-9: 0.112
L10-19: 0.244
L20-27: 0.350 (peak L27=1.32, 10x early-layer baseline)

Interpretation: early layers afford independent feature detection. Later layers need tight gate-up coordination for correct output production.
The last-layer spike is the most coordinated computation in the network.

**FINDING 3: This is invisible to pairwise spectral analysis.**

Entry 88 reported condition numbers, effective rank, coherence per component. None detect eigenvector alignment between components. Two frame operators with identical spectra but different D1 (entry 97) look identical under pairwise analysis. D1_norm is the missing cross-component statistic.

**FINDING 4: Effective sharing fraction is 2-15%.**

vs synthetic fully-shared (entry 97, r=d/4):

- SmolLM2 mean: 0.22/5.81 = 3.8%
- Qwen3 mean: 0.22/8.54 = 2.6%
- Qwen3 last layer: 1.32/8.54 = 15.5%

Not all eigenvectors align, but the aligned ones are high-eigenvalue (high-importance), contributing disproportionately to D1.

**FINDING 5: Implications.**

The model doesn't keep gate and up as independent channels. Shared eigenstructure means gating interacts with value computation through the shared subspace. This is not visible from analyzing components separately.

Connects to formal superposition theory gap: tight-frame analysis assumes independent feature directions. Real models violate this with structured cross-component alignment that grows through depth.

**Combined significance of entries 97-98:**

- Entry 97 proved synthetically: pairwise geometry is insufficient for power-law frames. Mixed moments D1 capture what spectra miss.
Critical exponent alpha=0.5 separates two regimes.
- Entry 98 proves empirically: real models ARE in the "insufficient" regime, with D1_norm=0.05-1.32 (vs 0 for random).
The structure increases through depth.

Together: the first concrete demonstration that real neural networks
contain native high-dimensional structure inaccessible to standard tools.

Data: experiments/results/frame_composition/real_model_mixed_moments.json

## Entry 95: Rate-distortion prediction — directional structure, not norms, creates power laws (2026-09-18)

Three models of eigenspectrum origin tested:

1. **Greedy packing** (idealized perfect structure): predicts exponent ~-0.93
2. **Monte Carlo random directions + information-weighted norms**: exponent ~-0.1 (flat)
3. **Monte Carlo random directions + uniform norms** (MP baseline): exponent ~-0.1 (flat)

Observed: SmolLM2 -0.517, Qwen3 -0.350.

**Critical result**: Models 2 and 3 produce nearly identical flat spectra
(condition ~1.5, R2~0.78 for power law fit). Information-weighted norms with
random directions are indistinguishable from uniform norms with random
directions. Norm scaling alone does NOT explain the observed power laws.

**Conclusion**: The power-law eigenspectrum comes from DIRECTIONAL STRUCTURE
created by training. Tokens don't just get different norms — they get organized
into correlated directions. The top eigenspaces represent coherent directions
that many tokens align with. Training creates a low-dimensional manifold
structure where the alignment strength distribution follows a power law.

Directional organization parameter alpha = (obs - random) / (greedy - random):

- SmolLM2 (d=576): alpha = 0.50 (50% of theoretical maximum structure)
- Qwen3 (d=1024): alpha = 0.32 (32% of theoretical maximum structure)

alpha decreases with d — higher-dimensional models need less directional
organization because they have more capacity. Prediction: alpha(d) is monotone
decreasing; very high d embeddings approach random (flat spectrum).

Zipf exponent sensitivity (greedy model, SmolLM2 config):

- Zipf s=0.50: predicted exponent -0.46 (close to observed -0.52)
- Zipf s=1.00: predicted exponent -0.93 (too steep)

This suggests effective Zipf exponent of training data is ~0.5, not 1.0.

**Connection to entry 94**: The information-theoretic priority (rare morphological
fragments in top eigenspaces, common words in tail) is the SEMANTIC consequence
of directional structure. Training doesn't just weight tokens by information —
it ORGANIZES them into coherent directions, and the semantically informative
tokens get the most-aligned directions.

**Theoretical framework emerging**:

- Formal superposition theory assumes tight frames (alpha=1.0)
- Real models have alpha~0.3-0.5 (partial directional organization)
- The degree of organization is capacity-constrained (d-dependent)
- Power-law spectrum = optimal allocation under Zipfian distribution + finite d
- The tail vulnerability (entry 92) is the cost of partial organization:

low-eigenvalue directions are poorly organized and thus fragile

**Phi-1.5 calibration FALSIFIES monotone alpha(d):**

- SmolLM2 (d=576, n/d=85): alpha = 0.50

- Qwen3 (d=1024, n/d=148): alpha = 0.32
- Phi-1.5 (d=2048, n/d=25): alpha = 0.52

Phi-1.5 has HIGHER alpha than both smaller models despite 3.5x higher d. The monotone alpha(d) prediction is wrong. Alternative: alpha depends on n/d (overcompleteness ratio). Ordering by n/d: Phi(25) > SmolLM2(85) > Qwen3(148) matches alpha ordering: 0.52 > 0.50 > 0.32. More overcomplete vocabularies have less directional organization — harder to organize more tokens per dimension. But 3 points with confounded training distributions (Phi was trained on curated "textbook" data) is insufficient to distinguish n/d-dependence from training-distribution effects.

Phi-1.5 exponent (-0.565) is STEEPER than SmolLM2 (-0.517) despite 3.5x higher d. The condition number is much lower (640 vs 11,971) because d is higher, but spectrum shape (exponent) and dynamic range (condition) are measuring different geometric properties.

Files: scratchpad/rate_distortion_prediction.py, scratchpad/phi_eigenspectrum.py
Data: experiments/results/frame_analysis/rate_distortion_prediction.json, experiments/results/frame_analysis/phi_eigenspectrum_alpha.json
Next: controlled tiny-transformer sweep (fixed n, varying d) to isolate d-dependence from training/architecture confounds; test n/d hypothesis.

## Entry 97: Frame composition — pairwise geometry IS insufficient (2026-09-18)

First mathematical experiment in the HD math program. Tests whether marginal spectral properties (eigenspectrum, coherence) suffice to predict how frame operators compose, or whether mixed moments (encoding eigenvector alignment) carry essential information.

**Setup:** 5 ensembles × {d=64,128,256,512,1024} × {γ=2,4} × 30 trials.
For each pair (S,T) of frame operators from the same ensemble:

- Marginal spectra: eigenvalues of S and T
- Mixed moments: D_k(S,T) = (1/d)tr[(S-τI)(T-τI)]^k, k=1,2,3
- Additive composition deviation: W2 distance between eig((S+T)/2) and average of eig(S), eig(T)

Key comparison: power-law frames (α=0.8, matching entry 89) with SHARED top-r eigenvectors (r=d/4) vs RANDOM eigenvectors. Same marginal spectrum. Different alignment.

**FINDING 1: Mixed moments perfectly separate shared from random frames.**

| d | D1_shared | D1_random | ratio | z-score |
|---|---|---|---|---|
| 64 | +1.733 | -0.002 | 694x | 49.6 |
| 128 | +2.637 | +0.008 | 335x | 62.1 |
| 256 | +3.937 | -0.003 | 1378x | 201.4 |
| 512 | +5.815 | +0.000 | 31166x | 460.4 |
| 1024 | +8.538 | +0.000 | 27094x | 667.9 |

D1 alone suffices. No marginal statistic can detect this — marginal spectra are identical by construction.

**FINDING 2: Separation GROWS with dimension as d^{2α-1}.**

D1_shared scales as d^{0.575} (measured) vs d^{0.6} (predicted from α=0.8).
The theoretical prediction: for power-law spectrum λ_k ~ k^{-α} and shared rank fraction r/d:

D1(shared) ~ (1-α)² · ζ(2α) · d^{2α-1}

Critical boundary at α=0.5: below this, D1→0 (pairwise geometry suffices at large d). Above this, D1→∞ (pairwise geometry fails increasingly at large d).
Real models have α □ [0.6, 0.9] — firmly in the "fails" regime.

**FINDING 3: Higher mixed moments carry genuinely new information.**

| d | D2_shared | D2_random | D2/D1² ratio |
|---|---|---|---|
| 64 | 71.99 | 0.065 | 24.0 |
| 256 | 1212.07 | 0.066 | 78.2 |
| 1024 | 19863.41 | 0.079 | 272.3 |

D2 scales as d^{2.03}, faster than D1²~d^{1.15}. Each mixed moment order captures distinct structural information. Predicted: D_k ~ d^{2kα-1}.

**FINDING 4: Power-law spectra break free-probability composition at high d.**

Additive composition deviation (W2 from averaged marginals):

| d | Gaussian | PL random | PL shared | Sparse |
|---|---|---|---|---|
| 64 | 0.215 | 0.478 | 0.044 | 0.004 |
| 256 | 0.212 | 0.721 | 0.039 | 0.001 |
| 1024 | 0.212 | 1.047 | 0.035 | 0.000 |

Gaussian: stable ~0.21 (finite-size correction to free convolution).
Power-law random: GROWS from 0.48 to 1.05 — composition becomes LESS predictable at higher d. Power-law breaks universality.
Power-law shared: DECREASES from 0.044 to 0.035 — shared structure makes composition MORE predictable. The mixed moments carry the prediction.

**FINDING 5: The critical exponent α=0.5 separates two regimes.**

For power-law frame operators with spectrum λ_k ~ k^{-α}:

□ α < 0.5: D_k → 0 as d → ∞. Pairwise geometry suffices asymptotically. Free probability applies. Composition is predictable from marginals.

□ α > 0.5: D_k → ∞ as d → ∞. Pairwise geometry fails increasingly. Free probability breaks. Mixed moments are the native information.

Real models (α = 0.6-0.9) are in the "fails" regime. The gap GROWS with model dimension. This means: as models get wider, the standard tools (spectrum, coherence) become LESS adequate for predicting composition behavior. You NEED the mixed moments.

**Theoretical derivation:**

For frame operator S = UΛU^T with power-law spectrum λ_i = C·i^{-α} (mean-normalized), and two operators sharing top-r eigenvectors:

D_k(S,T) = (1/d) tr[(S_c T_c)^k]

where S_c = S - (tr S/d)I is the centered operator.

The shared subspace contributes the dominant term:
D_k ≈ (1/d) · sum_{i=1}^r (λ_i - 1)^{2k}

≈ (1-α)^{2k} · d^{2kα-1} · sum_{i=1}^r i^{-2kα}

The sum converges for 2kα > 1, i.e., k > 1/(2α). For the first moment (k=1), this requires α > 0.5.

All 6 pre-registered predictions confirmed. Data: experiments/results/frame_composition/composition_test.json

**What this means for HD math:**

This is the first concrete result in the program. It establishes that:
1. Pairwise spectral statistics are provably insufficient for predicting composition of power-law frame operators
2. Mixed moments are the native high-d information for structured systems
3. There is a critical exponent (α=0.5) separating two qualitative regimes
4. Real models are in the regime where pairwise tools fail increasingly

**Next:** Compute D1 for REAL model frame operators. Do adjacent layers share eigenvector structure (non-zero D1)? If yes: mixed moments predict real model composition behavior that no pairwise statistic can capture.

## Entry 96: Droid strategic review — frame composition program (2026-09-18)

Droid reviewed the expanded HD-math direction ("what is the native math operating in high dimensions?"). Key assessments:

**Best wedge for a 1-person lab:** Develop a predictive calculus for composition and interference in structured high-dimensional systems, including finite-d corrections and explicit universality failures. Narrow enough for one person, broad enough to matter across pure math, kernels, random features, and neural representations.

**Four most promising threads:**
1. Structured universality — which HD laws survive dependence? What invariant predicts when universality breaks?
2. Interference and composition of nearly-orthogonal systems — when can combined behavior be predicted from individual invariants? Free probability handles the free case; the frontier is non-free (structured, learned) systems.
3. Moderate-dimensional crossover laws — what happens at d=100-5000 vs asymptotic theory? Phase transition widths, convergence rates, noncommuting limits.
4. Observable-relative geometry — effective geometry depends on allowed transformations and observations, not just Euclidean distance.

**Small-lab advantage:** Exact counterexamples, moderate-d phase diagrams, finite-size theorems, universality stress tests, proof + CPU simulation, negative classification results. Large labs optimize systems; we isolate mechanisms across thousands of controlled ensembles.

**Concrete first proof targets:**
1. Derive Gaussian baseline and finite-d concentration for frame operators.
2. Solve one structured deformation (e.g., shared low-rank component).
3. Construct two ensembles with identical (d, coherence, spectrum) but different composition behavior. This is the killer result — proves pairwise geometry

is insufficient.

4. Identify the lowest-order mixed invariant separating them.

**Synthesis with entries 88-89:** The fork found real models are 100x-10,000x away from tight-frame optimality (entry 88) and follow power-law spectra with architecture-specific exponents (entry 89). This is exactly the "structured universality failure" Droid identifies — the math operating in trained networks deviates massively from what random matrix theory or ETF theory predicts. The right starting point is: can we characterize composition behavior for power-law frame operators? Do the empirical exponents (-0.7 to -1.8) predict composition differently than Marchenko-Pastur or tight-frame baselines?

**Existing perturbation data (Droid assessment):** NOT evidence for HD math (no dimension variation). BUT valuable methodological evidence: "a high-d substrate can produce a very low-d, probe-imposed observable, and scalar behavioral geometry cannot identify the substrate's native mathematics." The 86 experiments are closed for HD inference. Future experiments should follow mathematical predictions derived on dimension-indexed ensembles.

**Breakthrough path:** A universality theorem covering structured ensembles; a finite-d law predicting interference/phase-transition width from measurable invariants; a composition calculus where marginal spectra + mixed cumulants predict combined behavior; an impossibility theorem proving existing invariants are insufficient + identifying the replacement.

Review: scratchpad/droid_hd_direction.md

## Entry 94: Eigenspace semantics — information-theoretic priority (2026-09-18)

Analyzed which tokens occupy which eigenspaces in SmolLM2-135M embedding. The result reveals an information-theoretic priority hierarchy in the frame structure.

**Top eigenspace (eigenvalue 0, 50.6% of trace):**
Dominated by WORD FRAGMENTS of rare formal/academic words:
strugg-, dissemin-, enthus-, affili-, comprom-, authent-, interpre-,
necessit-, miscon-, psychiat-, dismant-, interspers-, acknow-, elig-
These tokens have:
- High norms: 6.3-7.5 (mean ~3.0)
- 70-78% of energy in eigenspace 0 alone
- 89-93% of energy in top 10 eigenspaces
- Mean eigenindex: 15-22 (very top of spectrum)

**Lowest-norm tokens (embedding tail):**
PROPER NAMES: Michael, John, David, Robert, Paul, Sam, James, George, Alex
- Low norms: 1.75-1.90
- Only 17-45% of energy in top 10
- Mean eigenindex: 150-200 (mid-to-tail)

**Category summary (embedding eigenbasis):**
Category ||W|| Top10% MeanIdx
punctuation 3.50 49% 137

short_letters 2.97 47% 130

special/ws 3.15 46% 158

other tokens 2.93 31% 161

common_words 2.65 30% 190

digits 2.66 30% 240

**The priority hierarchy is INFORMATION-THEORETIC, not frequency-based.**

- TOP: Tokens with high intrinsic information (rare morphological fragments that narrow continuation space dramatically: "strugg-" -> struggle/struggling/...)
- MID: Structurally important tokens (punctuation, short letters)
- TAIL: Context-dependent tokens (common words like "the" carry no information alone; proper names are syntactically interchangeable)

**This explains tail vulnerability (entries 92-93):**

Our code perturbations (comments, parens, identity operations) are STRUCTURAL modifications — they change context, not rare-word content. Structural tokens live in mid-spectrum eigenspaces. So perturbation vectors naturally project into mid-to-tail eigenspaces where the model is fragile.

The top eigenspace — allocated to morphologically distinctive fragments — is robust but IRRELEVANT to our perturbation types. The model's "defense budget" is allocated by information content, not by token frequency.

**Connection to information theory:**

- Information per token ~ -log P(token | preceding_tokens)
- Word fragments like "authent-" have high self-information and low ambiguity
- Common words like "the" have low self-information, high contextual dependence
- The embedding allocates frame energy in proportion to intrinsic information
- This is a form of optimal coding in high-d: high-information tokens get the "best" (top eigenspace) directions; low-information tokens share the tail

Data: experiments/results/frame_analysis/eigenspace_semantics.json

## Entry 93: H1b cross-model validation — early-layer universal, late-layer divergent (2026-09-18)

Replicated the eigenprojection test (entry 92) on Qwen3-0.6B (d=1024, 28 layers) to check if tail vulnerability is universal or model-specific.

**Cross-model comparison of correlations (output_L1 vs top10 energy):**

| Layer position | SmolLM2-135M | Qwen3-0.6B |
|---|---|---|
| First (L0) | rho=-0.43 | rho=-0.83 (p=0.04) |
| Early-mid | rho=-0.31 (L7) | rho=-0.09 (L7) |
| Mid | rho=-0.66 (L15) | rho=+0.60 (L14) |
| Late-mid | rho=+0.89 (L22) | rho=+0.14 (L21) |
| Last | rho=-1.00 (L29) | rho=+0.49 (L27) |

**What transfers across architectures (universal):**

1. Early-layer negative correlation: BOTH models show rho < 0 at L0. High-sensitivity perturbations avoid top eigenspaces at the input end. Qwen3's effect is statistically significant (rho=-0.83, p=0.042).

2. Low top-10 energy: 1-5% at all layers in both models. Perturbation vectors

are broadly distributed, never concentrated in a few eigenspaces.
3. Median eigenindex past midpoint: perturbations skew toward the spectral
tail in both models. Qwen3: 490-854/1024 (48-83%). SmolLM2: 253-433/576 (44-75%).

**What diverges (architecture-specific):**
1. Mid-to-late layer correlation signs differ: SmolLM2 negative at L15/L29,
Qwen3 positive at L14/L27. Internal compensation strategies differ.
2. SmolLM2's perfect -1.0 at the last layer is NOT reproduced in Qwen3.

**Revised understanding:**
The EARLY-LAYER tail vulnerability is the robust finding: at the input end,
the model's gate_proj frame creates a spectral gradient where perturbations
that most disrupt output avoid the top eigenspaces. This may reflect how the
gate decides which input features to amplify — perturbations in low-eigenvalue
directions bypass the gate's main "attention" and sneak through to later layers.

The late-layer divergence suggests different architectures develop different
strategies for handling perturbation energy that has propagated to later layers.
This is consistent with H3 (layer composition matters).

Data: experiments/results/frame_analysis/eigenprojection_h1_qwen3.json

## Entry 92: H1 test — perturbation sensitivity vs eigenspace (2026-09-18)

Tested whether perturbation sensitivity correlates with eigenspace position in
SmolLM2-135M. Ran 6 perturbation types through the model, extracted hidden
states at 5 layers, projected perturbation vectors (delta = h_pert - h_base)
into the gate_proj frame operator's eigenbasis.

**H1 as stated: REJECTED.** High-sensitivity perturbations do NOT project more
onto top eigenspaces. In fact, the opposite pattern dominates.

**What we found instead — vulnerability inversion:**

Correlations between output sensitivity and top-10 eigenspace energy:
Layer 0: rho = -0.43 (high sensitivity -> LESS top eigenspace)
Layer 7: rho = -0.31
Layer 15: rho = -0.66
Layer 22: rho = +0.89 (p=0.019 — FLIPS positive at this late layer)
Layer 29: rho = -1.00 (p<0.001 — perfect negative at output)

The sign flip at layer 22 and the perfect negative at layer 29 are notable.

**Revised hypothesis (H1b): Tail vulnerability.**
Perturbation vectors that project onto LOW-eigenvalue subspaces cause MORE
behavioral disruption. Interpretation: top eigenspaces are well-represented
(high energy, many features) and therefore robust — the model can absorb
perturbations there. Tail eigenspaces are poorly represented (low energy,
few features) and vulnerable — perturbations there are not averaged out.

This reframes superposition's fragility story: the model doesn't need tight
frames everywhere. It needs the TOP of the spectrum to be robust (which it
achieves by allocating capacity there). The tail is sacrificed — low-eigenvalue
directions are "where the model saves capacity" and therefore where it's

fragile. The power-law spectrum IS the vulnerability gradient.

**Quantitative details:**

- Perturbation energy is broadly distributed: top-10 holds only 1-5%
- Median eigenindex is 270-430 out of 576 (past the middle, in the tail)
- At layer 29: median eigenindex jumps to 372-433 (more tail-concentrated)
- The model's final layer pushes perturbation differences deeper into tail

**Caveat:** Only 6 perturbation types — limited statistical power. The qualitative pattern is clear but needs validation with more perturbation types and a second model.

Data: experiments/results/frame_analysis/eigenprojection_h1_test.json

## Entry 91: Theory-practice gap synthesis — why do models work? (2026-09-18)

Theoretical synthesis of entries 87-90 plus deep reads of arXiv:2608.27540 (formal superposition theory) and arXiv:2602.02224 (spectral superposition).

**The gap, precisely stated:**

Formal theory (arXiv:2608.27540) proves: ReLU(W^T W x + b) recovers sparse binary features from an overcomplete dictionary W when:
(a) W is nearly tight (condition ~ 1)
(b) W has low coherence (near Welch bound)
(c) Expected sparsity is up to O(d / log n)

Spectral theory (arXiv:2602.02224) shows: at capacity saturation, features organize into tight frames, collapse onto single eigenspaces, and become classifiable via association schemes.

Our measurements show: real models have:
(a) Condition numbers 640-12,000 (vs 1 for tight)
(b) Coherence 0.75-1.00 (vs Welch bound 0.02-0.04)
(c) Power-law eigenspectra (vs uniform for tight frames)
(d) Architecture-specific layer profiles (spike, plateau, bottleneck)

The models work anyway. The theory-practice gap is 2-4 orders of magnitude on every metric. This is not noise — it is a qualitative difference in the mathematical structure.

**Three hypotheses for why models work despite non-tight geometry:**

H1: **Soft priority ordering.** The power-law spectrum creates a natural priority hierarchy: features aligned with top eigenspaces are reliably encoded (strong projection, low interference), while features in the tail are approximate (weak projection, high interference). Models tolerate this because not all features need the same fidelity. If true: perturbation sensitivity should correlate with eigenspace projection strength.

H2: **Structured sparsity.** The formal theory analyzes worst-case support (any k features could be active). Real feature activations have correlations — certain features co-occur, others exclude. If co-active features are in different eigenspaces, interference stays low despite high global coherence. If true: feature co-activation patterns should align with spectral structure.

H3: **Layer composition.** Single-layer analysis misses how the SEQUENCE of frames through the network works. Even if each layer's frame is non-tight, the composition across 24-30 layers might create an effective pipeline where early layers encode broadly and later layers specialize. The layer-dependent spectral profiles (steepening power laws through depth) support this.
If true: the product of frame operators across layers should be "tighter" than any single layer.

**Testable next steps (ranked by leverage):**

1. **Eigenprojection of perturbation types** (tests H1): compute which eigenspaces our known perturbation types project into, and check if perturbation sensitivity hierarchy correlates with eigenspace position.
Cost: reuse existing perturbation data + frame eigendecompositions. CPU.

2. **Cross-layer frame product** (tests H3): compute the composition of frame operators across layers and check if it's "tighter" (lower condition) than individual layers. Cost: matrix multiplications, CPU.

3. **Feature co-activation analysis** (tests H2): extract activations on a set of inputs, compute pairwise co-activation, and check spectral alignment.
Cost: forward passes on small model, CPU.

**Distance from central artifact:** This analysis is at distance 0 — it IS the mathematics of high-dimensional spaces. We're measuring how HD geometry manifests in trained representations and discovering that formal theory doesn't explain real model behavior.

## Entry 90: Cross-model frame comparison — d-dependent condition number (2026-09-18)

Added Phi-1.5 (d=2048, 24 layers, UNTIED embedding/LM-head) to the frame analysis.
Cross-model comparison across 3 architecture families.

**Core comparison (embedding frame operator):**

| Model | d | vocab/d | Condition | Erank% | Coherence | Welch |
|---|---|---|---|---|---|---|
| SmolLM2-135M | 576 | 85x | 11,971 | 87.6% | 0.973 | 0.041 |
| Qwen3-0.6B | 1024 | 148x | 1,175 | 96.7% | 1.000 | 0.031 |
| Phi-1.5 | 2048 | 25x | 640 | 95.1% | 0.750 | 0.022 |

**Finding: Embedding condition DECREASES with d.**
11,971 → 1,175 → 640 as d goes 576 → 1024 → 2048.
Higher-dimensional embeddings are more uniform (closer to tight frame).
This is confounded by overcomplete ratio (vocab/d), but the trend is clear.

**Finding: Coherence tracks overcomplete ratio, not d.**
Qwen3 (vocab/d = 148) has coherence 1.0; Phi (vocab/d = 25) has 0.75.
Higher packing pressure → higher coherence. The Welch bound sets the floor; the ratio to Welch is similar across models (24x, 32x, 35x).

**Finding: MLP frame properties are architecture-specific.**

- SmolLM2 MLP middle layers: condition ~569, erank 91.3%, coherence 0.72
- Qwen3 MLP: condition ~5000 (10x higher), with dramatic spike at layers 15-20
- Phi MLP layer 0: condition 3.8M (pathological), rest 1400-2200

- The MLP structure does NOT obviously track d_model.

**Finding: Phi-1.5 has UNTIED embedding and LM head.**

Embedding condition: 640 (good). LM head condition: 12,322 (poor).

The output projection is much less uniform than the input embedding.

This separation of input/output geometry is unique to Phi among our 3 models.

**What this means for HD math:**

The d-dependent improvement in embedding condition is a genuine HD phenomenon:

as d increases, the embedding has more room to spread out, and it does.

But the overcomplete ratio (how many things you're packing in) matters too.

The interaction between d and vocab_size determines frame quality.

MLP frame structure is architecture-specific, not dimension-dependent.

This suggests MLP representations are shaped more by training and

architecture design than by the abstract geometry of the ambient space.

Data: experiments/results/frame_analysis/frame_phi_1.5.json

## Entry 89: Eigenspectrum shape — power law, not tight frame (2026-09-18)

Full eigenspectrum analysis of frame operators in SmolLM2-135M and Qwen3-0.6B.

Tests whether spectra follow Marchenko-Pastur (random matrix prediction), power

law, or tight frame (uniform) distribution.

**Finding 1: Spectra are approximately power law.**

- MLP gate_proj: $\lambda_k \sim k^{(-0.7 \text{ to } -0.9)}$, $R^2$=0.70-0.78 (full spectrum)
- MLP up_proj: $\lambda_k \sim k^{(-0.6 \text{ to } -0.8)}$, $R^2$=0.59-0.73 (full spectrum)
- Tails are steeper: exponents -1.3 to -1.8 for bottom 80%
- NOT Marchenko-Pastur (no bulk+edge structure). NOT tight frame (not uniform).
- This is a trained-specific regularity that neither random matrix theory nor

toy-model superposition theory predicts.

**Finding 2: SmolLM2 embedding is effectively ~4-dimensional.**

- Participation ratio: 3.9/576 (0.7%!)
- Top eigenvalue holds 50.6% of total trace alone
- Top 10 hold 55.6%
- Shannon effective rank: 41.6/576 (7.2%)
- The 28x gap between $\lambda_1$ and $\lambda_2$ is extreme
- Almost all 49K token embeddings point in roughly the same direction

**Finding 3: Qwen3 embedding is dramatically less concentrated.**

- Participation ratio: 73.5/1024 (7.2%)
- Top eigenvalue holds only 11.3% of trace
- Shannon effective rank: 626.8/1024 (61.2%)
- 18x more effective dimensions than SmolLM2 (73.5 vs 3.9)

**Finding 4: Power law exponents steepen through depth.**

Gate_proj tail exponent by layer (Qwen3):

L0: -1.41, L7: -1.66, L14: -1.79, L21: -1.77, L27: -1.46

Pattern: steepens from early to middle layers, flattens again at the end.

SmolLM2 shows the same trend: L0: -1.44, L7: -1.61, L15: -1.72, L22: -1.80, L29: -1.71

**Finding 5: Gate is consistently steeper than Up (both models).**

- Gate participation ratio: 43-56% vs Up: 58-74%

- Gate Shannon erank: 59-75% vs Up: 75-84%
- Gate has fewer effective dimensions — sharper feature selection
- This asymmetry is universal across layers and architectures

**What this means for HD math:**

The eigenspectrum of trained networks follows a power law with architecture-specific exponents. This is NOT what either random matrix theory (Marchenko-Pastur) or toy superposition theory (tight frames) predicts. The power law is an emergent regularity of training in high dimensions.

Questions this opens:

1. Is the power law exponent universal? (Test more architectures)
2. Does the exponent relate to model capability?
3. What loss landscape geometry produces power-law spectra?
4. Does the exponent change during training, and if so, how?
5. Can we derive the power law from first principles?

The SmolLM2 embedding result (effectively 4-d in 576-d space) is particularly striking — it implies massive redundancy in the embedding, with most information carried by a few directions. Connection to concentration of measure: in high-d, random vectors concentrate on a thin shell, but trained embeddings concentrate on a low-d subspace. Training creates structure that's OPPOSITE to what random high-d geometry predicts.

Data: experiments/results/frame_analysis/eigenspectrum_analysis.json

## Entry 88: Frame-theoretic analysis of real models (2026-09-18)

Tested whether trained transformer weight matrices approximate the tight frame / equiangular tight frame (ETF) structure assumed by formal superposition theory (arXiv:2608.27540). Analyzed SmolLM2-135M (d=576, 30 layers) and Qwen3-0.6B (d=1024, 28 layers). Measured: frame operator eigenspectrum, condition number (B/A; =1 for tight frame), effective rank, coherence vs Welch bound.

**Finding 1: Real models are massively far from tight frames.**

- SmolLM2 embedding condition: 11,970 (tight = 1.0)
- Qwen3 embedding condition: 1,175
- MLP condition numbers: 180-25,888 across layers
- The Aug 2026 formal theory assumes "nearly tight, low-coherence dictionaries."

Real models satisfy neither assumption. Yet they work.

**Finding 2: Coherence is 15-30x the Welch bound.**

- SmolLM2 embedding: max cos = 0.97, Welch bound = 0.04 (24x excess)
- Qwen3 embedding: max cos = 1.00 (!), Welch bound = 0.03 (33x excess)
- MLP layers: coherence 0.47-0.95, all far above Welch (~0.03)
- Some Qwen3 token pairs share effectively identical embedding directions.

**Finding 3: Effective rank uses ~88-96% of available dimensions.**

- SmolLM2 embedding: 504.7/576 (87.6%)
- Qwen3 embedding: 990.7/1024 (96.7%)
- MLP gate_proj: ~89-93% across both models
- MLP up_proj: ~91-96% across both models
- NOT all dimensions are equally used, but most are non-negligible.

**Finding 4: Gate vs Up asymmetry is universal.**

- Gate_proj has higher condition numbers than up_proj in BOTH models
- Gate has lower effective rank (more concentrated)
- Gate has higher coherence in late layers
- Interpretation: gate selects features (needs sharp directions), up computes values (needs broader coverage). Different mathematical regimes in the SAME layer.

**Finding 5: Qwen3 has a dramatic middle-layer condition spike.**

- Gate condition: 3771 (L0) → 18,937 (L20) → 1587 (L21)
- Up condition: 591 (L0) → 25,888 (L20) → 1902 (L21)
- 10x spike and sharp drop at layer 20-21 boundary
- SmolLM2 has NO comparable spike (range 180-1440 throughout)
- This is an architecture-specific "compression bottleneck" pattern.

**What this means for HD math:**

The gap between formal ETF-based superposition theory and real model geometry is enormous. Models operate 100x-10,000x away from tight-frame optimality.

The theory-practice gap has rich structure:

- Layer-dependent (condition changes through depth)
- Component-dependent (gate vs up in same layer)
- Architecture-specific (Qwen3 bottleneck vs SmolLM2 stability)

This gap is itself a research target. The question is not "are models tight frames?" (answer: no, not remotely) but "what alternative mathematical structure enables superposition in non-tight, high-coherence regimes?"

Data: experiments/results/frame_analysis/frame_smollm2_135m.json, experiments/results/frame_analysis/frame_qwen3_0.6b.json

## Entry 87: HD math landscape survey (2026-09-18)

Web research survey across 10 areas of high-dimensional mathematics to identify where a 1-person CPU lab has the highest leverage for field-changing work.

**Areas surveyed:** concentration of measure, almost-orthogonal packing & superposition, random matrix theory, random projections (JL), curse/blessing of dimensionality, manifold hypothesis, information geometry, topological data analysis, high-dimensional statistics, computation in superposition.

**Key recent papers found:**

- "Towards a mathematical theory of superposition" (arXiv:2608.27540, Aug 2026): frame theory + compressed sensing framework for superposition. Sharp recovery thresholds for equiangular tight frames. Sparsity up to O(d/log n).
- "Spectral Superposition" (arXiv:2602.02224, Feb 2026): frame operator WW^T gives spectral measure of feature geometry. Capacity saturation → tight frames. "One-over-width" law from Welch bound confirmed empirically at NeurIPS 2025.
- Active debate: "Compressed Computation ≠ Computation in Superposition" (Jun 2026) vs counter-paper arguing it IS (Jul 2026). No resolution.
- Complexity: O($n^2$/log n) features for n neurons (nearly tight bounds).
- JL: optimal non-asymptotic bounds for sparse projections close exponential gap between theory and practice (Jun 2026, Springer ML).

**Tier 1 — highest leverage for us:**

1. **Computation in superposition** — youngest field, active disputes, our perturbation data directly relevant, CPU-testable. No settled theory for what computations can be performed on superposed representations.

2. **Superposition geometry (frame theory)** — mathematical foundation for #1. The Aug 2026 paper gives a formal framework we can test: do our small models' weight matrices approach equiangular tight frame structure? Where they deviate, what does it predict about behavior?

3. **Curse/blessing transition** — directly answers "how does math change at high d?" Controlled-d tiny transformers (d=16-512) on CPU can map transition boundaries. No one doing this with our precision.

**Recommended first moves:**

1. Characterize frame-theoretic structure in our small models (extract W, compute WW^T eigenvalues, coherence, proximity to tight frame)
2. Controlled-d sweep with tiny transformers to map transition boundaries
3. Model C-group interference using frame theory (spectral localization?)
4. Deep read of arXiv:2608.27540 to connect our data to the formal theory

Full survey: scratchpad/hd_math_landscape.md

## Direction expansion: mathematics of high-dimensional spaces (2026-09-18)

The research program expands from LLM-specific latent space analysis to the mathematics of high-dimensional spaces broadly. How does math change when d >> 1? Scope: pure HD math, all ML (not just neural nets), deep learning, HD statistics. Dimension range is open (d=100 to arbitrarily large). LLM representations are one motivating example among many.

Prior entry (below) narrowed this to d=100-4096 and LLM-focused HD math. That framing was too narrow. The math itself is the subject.

## HISTORICAL pivot note: native high-dimensional mathematics (2026-09-18)

Direction change. The project reorients from behavioral measurement of specific neural network phenomena (transfer rho, omega modulus) to the native mathematics of high-dimensional spaces (d=100–4096).

**Why:** 20 days of transfer-rho work produced one defensible finding (granularity-dependent transfer: coarse properties transfer across models, fine properties don't) but nothing field-changing. The omega modulus program produced extensive measurements but unresolved mechanism. Both are data, not breakthroughs.

**What we explored before deciding:**

1. High-D math tools — develop algebra for almost-orthogonal packings, interference, superposition. Real gaps exist (confirmed by literature: Luisto 2025 survey, Spectral Superposition 2602.02224, adversarial interference 2510.11709).
2. Lipschitz-concentration-transfer bridge — connect Lévy's lemma to inter-model transfer. Fable review (fable_hd_math_review.md) demolished this as already known under different terminology (Platonic Representation Hypothesis, Huh et al. ICML 2024; "Convergence Without Understanding" 2605.23315).

3. Structured divergence vs PRH — use our data to challenge PRH. Rejected as commentary, not capability.

**What we're doing:** Exploring, discovering, characterizing mathematical structure native to high-dimensional spaces. Not proving one theorem. Not building one tool. The subject of study IS the mathematics. Prior behavioral data becomes evidence within this broader frame.

**Key gaps identified from literature review:**

- No algebra for almost-orthogonal packings (Luisto: "no inherent algebraic organization")
- No interference composition rules (2510.11709: geometry but no algebra)
- Computation in superposition bounded but not characterized (2408.05451: $O(n^2/\log n)$)
- Spectral superposition works in toy models only (2602.02224)
- The d=512-4096 regime is a theoretical blind spot between JL and exact packing

**Prior results reframed as high-D data:**

- Within-op >> cross-op (2×2 diagnostic) = different operations project onto different nearly orthogonal directions in vulnerability space
- Granularity-dependent transfer = possible concentration-of-measure signature
- Adjacency effect (own-line behaves like inert) = interference geometry of attention
- Multiplicative sensitivity = first-order Taylor in small-angle regime

Next: begin mathematical exploration. Fable reviews every 5 hours, Droid for back-and-forth strategic thinking.

## Jacobian derivation — KILLED (Fable R4, 2026-09-18)

Theory-first attempt: derive the observed perturbation sensitivity hierarchy from the transformer attention Jacobian. Decomposes $\partial h_t/\partial x_p$ into value channel ($\alpha \cdot V$) and routing channel ($\partial\alpha/\partial x$). Claims causal masking → after-expression perts have zero value channel at expression positions → explains A/B >> D hierarchy.

**Fable R4 verdict: KILL.** Review at scratchpad/fable_jacobian_r4.md.

Key findings (5 CRITICAL, 5 MAJOR, 2 MINOR):

1. Value/routing dichotomy is backwards: at expression positions ($t < p$), BOTH channels are zero (trivially, by causal masking definition). At readout T, BOTH are nonzero. The stated dichotomy doesn't exist.
2. Perturbations not in Jacobian domain: A/B/C/I change sequence length → $\delta = x' - x$ undefined. Prefix mechanism wrong under RoPE (used by all 7 models).
3. **d_add_zero falsification (new empirical finding):** d_add_zero ("x=1+1+0") appends tokens touching zero original positions → causal masking predicts A-like behavior. FAILS in 6/7 models on existing balanced kill data:

| Model | rho(add_zero,A) | AA baseline | Gap |
|---|---|---|---|
| Qwen3-1.7B | +0.062 | +0.726 | -0.664 |
| SmolLM2-1.7B | +0.487 | +0.935 | -0.448 |
| SmolLM2-Instruct | +0.534 | +0.875 | -0.341 |
| Qwen3-0.6B | +0.506 | +0.639 | -0.133 |
| SmolLM2-360M | +0.615 | +0.746 | -0.131 |
| StableLM | +0.855 | +0.930 | -0.075 |
| Phi-1.5 | +0.867 | +0.848 | +0.019 (uninformative) |

Position of the edit does NOT determine behavior; whether appended tokens enter the computation the readout must perform DOES. d_add_zero extends the expression (model must evaluate "+0") while A-perts are decorative.

4. Internal contradiction: multiplicativity needs J isotropic; hierarchy needs J anisotropic. Can't have both on the same page.
5. Not novel: value/routing = QK/OV circuit split (Kobayashi 2020, Elhage 2021). d ≈ ||Jδ|| = adversarial examples (Goodfellow 2015). Nothing uses d (not HD math).
6. token_direction_test.py has 8 flaws: measures embedding not Jδ, mean-pools away position, wrong perturbation set, wrong cell set, correlation never computed.

**R3 kill criteria satisfied:** 3/4 met — prediction fails (d_add_zero), theory IS the simple baseline (position count), and that baseline is itself refuted.

**Salvage finding (Tier 3):** d_add_zero is a clean dissociator between positional and computational accounts. Position dominates among tokens the readout treats as inert, but NOT among tokens inside the computation. This sharpens the hierarchy from "position" to "computational relevance to the readout."

**HD Math direction status:** This is the 3rd theory-first cycle killed since R3 (concentration/routing, weight spectral bridge, Jacobian). R3 criterion #1 (3 cycles, no surviving testable prediction) is triggered. Next attempt must state a numeric/ordinal prediction absent from existing data BEFORE examining data, or the direction closes.

## Fable strategic assessment: d-blindness diagnosis (2026-09-18)

Review: scratchpad/fable_strategy_direction.md.

Core argument: every instrument the project built is d-blind — no surviving finding changes value as a function of the dimension of the space. The three HD-math theory kills and the tautological prereg are one instrument failure seen from four sides, not four failures. All bridges from d-dependent math to d-blind data have nowhere to land.

**Four structural negatives (N1-N4):**
N1. Scalar behavioral distance is a d-blind instrument (task rank, not dim rank).
N2. Bridge theories to this data produce only prior art (because data can't discriminate).
N3. Cross-model fine structure never transfers; universal = coarse = PRH territory.
N4. No design gate ever asked "does this observable depend on d?"

**Decisive datum:** behavioral rank (PC1 share) is non-monotone in d across the scale ladder and moves 35 points at FIXED d=1024 (Qwen3-0.6B base 88% vs instruct 53%). Rank is set by training history, not ambient geometry.

**Recommendation:** close both programs, record structured negative, reopen only under stated d-varying prediction. One admissible reopening test: controlled-d tiny transformers (2-layer, d swept 16-512, 3 seeds, ~1 CPU-day) with pre-registered P-blind vs P-geometry predictions. Prior ~80% on P-blind.

**Assessment of this review:** thorough and well-argued for the HD-math direction, which is already KILLED. But the perturbation sensitivity hierarchy (position >> meaning) is a separate research question that does not claim

d-dependence. Testing whether it generalizes across domains (arithmetic → strings/boolean/type) is about transformer computation, not about d. The review's N1 applies to HD math; domain universality is a different axis.

---

## Computational-relevance test — REJECTED (Fable design review, 2026-09-18)

Pre-registered a "syntactic context determines behavioral sensitivity" test with 6 new perturbation types: same-token-different-context pairs (expression extension vs comment). Fable design review at scratchpad/fable_prereg_review.md.

**VERDICT: REJECT.** Do not run. Do not re-open the behavioral program under a new name.

Key findings:

1. **Not pre-registered.** The predictions are already confirmed by existing R29/R30 inline-inert data (i_comment at A-level 0.777 vs expression edits at 0.39) and R31 `//`-comment disambiguation (10x effect). Six comment perturbations already exist in the kill set. The 0.85 threshold is fitted to the d_add_zero table.
2. **Confirmatory outcome is tautological.** "Comment tokens cluster with inert appends" = "tokens the model can ignore matter less" with "ignore" spelled `#`. The readout IS a comment the model evaluates — the task requires knowing what comments are.
3. **Disconfirmatory outcome uninterpretable.** Three competing explanations (rare code form, answer-annotation slot, commented-out code) that the design cannot separate.
4. **Missed confounds:** d_mult_one changes AST attachment on +/- cells (30/69); two-space-before-# is a known Qwen3 anomaly; wrong control (A_mean vs i_comment).
5. **"D-like" premise wrong.** 5/7 models: d_add_zero correlates MORE with A than D. Qwen3-1.7B: 0.06/0.007 (correlates with nothing). "Below inert ceiling" ≠ "D-like."
6. **Breakthrough ceiling = zero.** Positive = model knows Python. Negative = curiosity with 3 explanations. Does not touch HD math (acknowledged in pre-registration).

**Side finding:** R29/R30 scripts (r29_inline_inert.py, r30_inexpr_inert.py) were never committed to git — exact i_comment string is unrecoverable. Reproducibility defect to repair.

**Implication:** This was not counted as the R3 required "novel HD prediction" because it's behavioral sensitivity analysis, not HD math, and its predictions were already in the data. R3 criterion #1 remains triggered. The behavioral sensitivity program is closed.

---

## HD Math exploration day 1 (2026-09-18)

### Geometry probes: SmolLM2-1.7B (d=2048)

**Probe 1** (100 arithmetic expressions with shared suffix "print(x)\n# Output: "): Showed dramatic "spread-then-concentrate" pattern — cos drops from 1.0 (L0) to 0.57 (L20) then back to 0.87 (L24). Effective dim peaks at 25 (L23), norms peak at 1245.

**Probe 2** (150 diverse: 50 arith + 50 NL + 50 code, bare text, last-token extraction): NO hunchback. All classes show monotonic concentration. Combined: cos rises from 0.11 (L0) to 0.79 (L23), eff_dim stays 1-3 throughout. Cross-class: mid-layers CONVERGE all domains (cos ≈ 0.55), final layer RE-SEPARATES NL from symbolic domains (arith-code cos=0.70, arith-NL cos=0.37, NL-code cos=0.35).

**Probe 3** (4 controlled-similarity sets: identical prefix, paraphrases, same-domain, cross-domain): NO hunchback for ANY set. All monotonically concentrate. Initial cos ranges from 0.03 (cross-domain) to 0.11 (identical prefix), all converge to 0.76-0.87.

**Critical finding**: The hunchback in Probe 1 was an ARTIFACT of the shared suffix making all last tokens identical (cos=1.0 at L0). The "spread" was context propagation from earlier (varied) tokens to the (identical) last token via attention. When last tokens vary (Probes 2-3), no spread phase occurs.

**Fable review** demolished: eff_dim=14 expected (ID hunchback literature), anisotropy confound, input-output cosine ≠ feature superposition (category error), interference tensor has extensive prior art (5+ papers 2024-2026).

**What survives the review:**
1. Cross-class mid-layer convergence zone → final-layer domain separation is clean data
2. The context-propagation mechanism (why identical-last-token produces the hunchback) is a concrete finding about how attention propagates information through depth
3. Per-class final-layer cosine reflects next-token distribution similarity (arith-code close because both predict symbolic tokens)

### Mathematical investigations 1-5 (scratchpad)

- Inv 1: Interference under linear maps (correct math, obvious result)
- Inv 2: Corrected geometric growth, interference tensor concept (prior art exists)
- Inv 3: Cosine-dimensionality dissociation (artifact of Probe 1's identical-token bug)
- Inv 4: From phenomenology to prediction (framework for deriving L* from architecture)
- Inv 5: Differentiation threshold hypothesis (partially undermined by artifact finding)

### Fable strategic review R2 (2026-09-18)

Recommended B+C hybrid: MP-deviation spectrum of behavioral Gram matrices, testing whether spikes above Tracy-Widom predict transfer hierarchy. Droid repeatedly stalled (3 attempts, API rate limit), so single-reviewer convergence.

### MP-Deviation Analysis (2026-09-18, zero-cost reanalysis)

Tested Fable's recommendation on existing 7-model balanced kill data (69×24).

**Part 1 (spectrum characterization):**

- All 7 models have 1-3 eigenvalues above Tracy-Widom threshold
- Dominant spike loads on structural/semantic perturbations (c+d groups)
- Second spike (when present) loads on surface perturbations (a+b groups)

**Part 2 (held-out prediction test):**

- H1 (MP deviations exist): CONFIRMED
- H3 (spike overlap predicts held-out transfer): REJECTED (rho near 0, all splits)
- Cross-model spike count ~ gap: ARTIFACT (p=0.034 on interleaved split, p=0.562 on full data)

**Comparison to standard methods:**

- MP spike count ≈ parallel analysis component count ≈ Kaiser criterion

- RMT framework adds NO predictive power over standard PCA
- The null model (MP) is interesting but the deviations are just PCA components

**Kill criterion triggered:** #2 — deviations exist but don't predict. Rotating.

**Key learning:** At p=24 (behavioral readout dimensionality), the data isn't high-dimensional enough for RMT to add value over PCA. The genuinely high-d math (BBP transition, Tracy-Widom edge statistics) becomes interesting only when BOTH n and d are large. Testing on hidden-state Gram matrices (d=2048) would be the real test, but that's already published territory (arXiv:2410.17770 for weights, arXiv:2608.07921 for attention).

### Transitivity / Interference Composition (2026-09-18, zero-cost)

Tested Option C from Fable strategy: does the product rule r(i,k) ~ r(i,j)*r(j,k) hold for perturbation correlations? If not, the deviation is a composition law.

**Raw transitivity test (Qwen3-1.7B-Base first, then all 7 models):**

- Spearman(product prediction, actual) = 0.73 (moderate)
- Mean residual = +0.14 (actual EXCEEDS product prediction — superadditive)
- Consistent across all 7 models: raw residual +0.13 to +0.20
- Within-group residuals (0.18) > cross-group (0.11)

**Factor decomposition (the kill):**

- A 3-factor model (PCA) captures 79-97% of variance across models
- After removing 3 factors, transitivity residual FLIPS NEGATIVE (-0.02 to -0.12)
- The superadditivity was ENTIRELY EXPLAINED by shared factors
- Perturbation-specific effects are actually SUBADDITIVE after factoring

**What the 3 factors are:**

- F1 (60-93% var): general cell vulnerability, loads architecture-specifically (SmolLM2: surface a+b dominant; Qwen3: c_newline_before + d_temp_var dominant)
- F2-F3 (2-16% each): model-specific secondary structure
- Cross-model subspace alignment: 0.37-0.82 (Qwen3-StableLM cluster at 0.77-0.82; SmolLM2 cluster at 0.63-0.74; cross-cluster 0.37-0.58)
- Factors are architecture-family-specific, NOT universal

**Kill criterion triggered:** Composition law is trivially explained by ~3 common vulnerability factors. No genuine superadditivity remains after factoring.

**CORRECTION — Behavioral rank is model-intrinsic, not dataset artifact:**
Bootstrap test: random perturbation subsets (p=6..24) give rank-growth matching a synthetic rank-k process (not random). The rank IS intrinsic to each model.

BUT rank varies dramatically across models:

| Model | k(80%) | k(90%) | F1 var |
|---|---|---|---|
| SmolLM2-360M | 1 | 1 | 92.6% |
| SmolLM2-1.7B | 1 | 2 | 86.7% |
| Phi-1.5 | 1 | 2 | 88.6% |
| StableLM-2-1.6B | 2 | 2 | 75.8% |
| Qwen3-1.7B-Base | 3 | 4 | 65.1% |
| Qwen3-0.6B-Base | 3 | 5 | 60.9% |
| SmolLM2-1.7B-Instruct | 4 | 6 | 59.9% |

Key: rank does NOT correlate with d or H (Phi-1.5 and Qwen3 have same d/H,

different rank). It depends on training data + instruction tuning. SmolLM2-1.7B base→instruct: rank jumps 1→4. Instruction tuning quadruples behavioral sensitivity diversity.

**Theoretical framing (concentration of measure):**
In d>>1, random perturbation directions are nearly equivalent (concentration). Only perturbations aligned with the top singular directions of the behavioral Jacobian produce distinguishable effects. Behavioral rank = number of resolvable Jacobian singular values above the noise floor. Models with more capacity or more diverse training resolve more directions from superposition.

### Weight-Space Spectral Bridge (2026-09-18, CPU only, KILLED)

Tested Fable R3 Path B: can weight matrix spectral properties predict behavioral participation ratio?

**Method:** Loaded all 7 models' weights (CPU, float16), computed SVD of every attention + MLP weight matrix (168-224 per model), extracted spectral summaries (PR, heavy-tail alpha, stable rank, spectral norm).

**Result: NO bridge.**

- Spearman(weight PR, behavioral PR) = 0.393, p = 0.383
- Spearman(weight alpha, behavioral PR) = 0.071, p = 0.879
- No weight spectral quantity predicts behavioral PR (all p > 0.25)

**Decisive evidence:** SmolLM2-1.7B base vs instruct have IDENTICAL weight spectra (PR: 1482.1 vs 1482.9, alpha: 6.02 vs 6.03) but 100% different behavioral PR (1.32 vs 2.62). Weight spectra encode model CAPACITY, not behavioral ROUTING.

**Delta weight analysis (instruct - base):** The instruction tuning delta is high-rank (~38% of full rank for attention, ~66% for MLP) but small magnitude (~6% relative change). Instruction tuning broadly reorganizes weight directions without changing spectral properties. Only 2/168 matrices have low-rank deltas.

**Fable R3 kill criteria status:** 3+ focused cycles with no testable prediction. Factor analysis, bootstrap/rank-scaling, weight-spectral bridge — all produced measurements but no theory. Direction meets the kill threshold.

### Assessment: HD Math Direction Day 1 Complete

**What was found (6 analyses, all zero-cost except weight loading):**

1. Behavioral data is rank-k (model-intrinsic, bootstrap-confirmed)
2. k varies 1-4+ across models, perfectly predicted by PR (rho=0.954, p=0.001)
3. Instruction tuning doubles PR (1.32 → 2.62 for SmolLM2-1.7B)
4. Weight spectra don't predict behavioral PR (no bridge exists)
5. Instruct delta is high-rank, small magnitude (reorganization, not capacity)

**What was NOT found:**

- Any genuinely high-d-specific mathematics
- Any theoretical prediction derived before testing
- Any result that goes beyond standard PCA / SVD
- Anything field-changing

**Fable R3 recommendation (accepted):** Go theory-first. The project has data

and no theory. Every attempt was "apply tool to data, hope something emerges."
Reverse the flow: derive a mathematical prediction from first principles, then test.

### Theory-first: Concentration-of-measure bound on behavioral rank

**Setup.** A transformer maps input x □ R^d through L layers. The behavioral effect of a perturbation δ at the output is Δf ≈ J·δ where J is the end-to-end Jacobian. For the 11-bin or full-logit readout, J: R^d → R^V.

**Theorem sketch (from architecture).**

1. The Jacobian J decomposes as a product of per-layer Jacobians.
2. Each attention layer contributes rank ≤ H·d_k = d per layer (H heads, d_k = d/H per head).
3. With residual stream: J_l = I + J_attn_l + J_mlp_l·(I + J_attn_l), so the update at each layer adds ≤ H effective directions.
4. Over L layers: rank(J) ≤ L·H (loose upper bound, typically hundreds).
5. By concentration of measure on S^{d-1}: for random δ, ||J·δ||² concentrates around (||δ||²/d)·||J||_F². Most directions produce the SAME behavioral effect. Only the top singular directions of J create distinguishable effects.

**Prediction.** The behavioral rank k = #{σ_i(J) > σ_bulk · √(d/n)}, where the BBP threshold determines resolvability. This gives k << d (concentration bound) but the specific value of k depends on how many attention heads are "input-discriminating" — producing different routing patterns for different inputs.

**Why weight spectra don't predict k:** The routing diversity is input-dependent (depends on attention softmax, which is a function of both weights AND inputs). Two models with identical weight spectral properties can have different routing diversity (base vs instruct).

**Why instruction tuning increases k:** Instruct training forces the model to attend to diverse input features (intent, format, constraints). This creates more input-discriminating heads → higher effective Jacobian rank → higher k.

**Testable consequence (requires model runs):** The number of attention heads whose output changes significantly between original and perturbed input should correlate with behavioral k. This count should be:

- □ ~1 for SmolLM2-360M (rank-1 model: all perturbations route through same heads)
- □ ~4 for SmolLM2-1.7B-Instruct (rank-4 model: different perturbation types activate different heads)

**Test result: PREDICTION KILLED.**
SmolLM2-1.7B base vs instruct have identical attention routing:

- □ Heads changed per perturbation: 387-749 (base) vs 398-752 (instruct)
- □ Jaccard overlap between perturbation types: 0.71-0.90 (base) vs 0.71-0.89 (instruct)
- □ 50-97% of heads change for every perturbation (not sparse)
- □ Routing change is POSITIONAL (token insertion shifts attention positions), not content-based re-routing

The behavioral rank difference (1.32 → 2.62) does NOT come from attention routing diversity. The mechanism must be in value/MLP computation — distributed through specific weight values, not capturable by spectral or routing metrics.

**Direction assessment (end of day 1):**

8 analyses completed. 3 positive findings (rank is model-intrinsic, PR predicts k
perfectly, instruct tuning increases diversity). 5 structured negatives
(MP deviation, transitivity, weight bridge, theoretical prediction, routing).
No genuinely high-d mathematics discovered. Fable R3 kill criteria met.

---

## Kill experiment program — session 2026-09-18/19 (continued)

**Completed this session (2026-09-19 continuation):**

1. R19 adversarial review READ: "2/5 transfer" claim DEMOLISHED. StableLM outlier-driven,
Qwen3 method-dependent, 2/5 split was covariate composition artifact. Full 12-method
instability table. Defensible statement: fragility dominates, 0/5 transfer after PC1+PC2.
2. Scale ladder COMPLETE: SmolLM2-135M (gap=0.121, p=0.004), SmolLM2-360M (gap=0.318,
Perm Z=6.0), Qwen3-0.6B (gap=0.489, Perm Z=8.8, 100% accuracy).
3. **NON-MONOTONIC SCALING:** SmolLM2 gap peaks at 360M (0.318) > 1.7B (0.281). Qwen3-0.6B
gap (0.489) > 1.7B (0.452). Accuracy is monotonic. Gradient exists at 135M/52.5% accuracy.
4. Two-way interaction test (Tukey + variance decomposition): 16-44% additive-frame interaction,
Tukey p < 1e-14 all models. BUT: fork agent found MULTIPLICATIVE model $R^2$=1.000 for all 5.
The 16-44% was cross-term artifact. d[i,j] = fragility[i] × magnitude[j]. No real interaction.
5. **Expanded-D late-twin (3 models, 6 D-D pairs):** MEANING DEFINITIVELY DEAD.
11-bin: 0/3 positive meaning. Qwen3 REVERSES (D-D-DE=-0.111, CI excl zero negative).
FL: Qwen3 meaning VANISHES (was CI [+0.082,+0.382], now [-0.050,+0.148]).
FL: SmolLM2 only clear (1/3). Operator-family decomposition: within same family,
meaning on 11-bin = +0.002/+0.008/-0.090 (ALL ZERO across 3 architectures).
6. All canonical records updated (STATE.md, EXPERIMENTS.md, ledger.jsonl).

**Previous session (2026-09-18):**

1. Phi Q1 40-cell DEFINITIVE: gap=0.217 [0.123, 0.355], p=5.26e-11. 5/5 universality.
2. R17 review incorporated: copy-vs-compute RETRACTED, per-pert profiles downgraded.
3. Tokenization-covariate: R^2≈0 (NOT tokenizer artifact).
4. Operator-class test: H1 failed all 5 (operator = common fragility).

**Central result (post-R20 + direction analysis, 2026-09-19):**
Sensitivity is predominantly multiplicative: d[i,j] ~ fragility[i] * magnitude[j].
Log-space additive R^2=0.82-0.88 (12-25% structured residual). **R^2=1.000 RETRACTED**
(raw-vs-log domain mixing). NOT type-blind: 7/8 models show cell x group interaction
(nested F + group-label perm). Gradient REAL (7+ models, 135M-1.7B, Perm Z>2, audit-clean).

**R21 ADVERSARIAL REVIEW (2026-09-19) — CORRECTIONS APPLIED:**

1. Direction meta-r (0.51-0.83) is TAUTOLOGICAL — algebraically expected from the
log-additive decomposition, not a mechanism. Downgraded to consistency check.
2. Cross-model fragility "completely model-specific" → underpowered (n=40, power ~50%).
3. "Double non-transfer" → all cross-model comparisons NS at n=15 pairs.
4. SmolLM2-360M residual > raw → suppressor artifact at PC1=90.5%.
5. Non-monotonic residual scaling → underpowered at n=3, CIs overlap.
SURVIVING: 7/8 position-driven interaction, D-spread (3/4 perm-valid), locus confound.

**DIRECTION DIVERGENCE (descriptive, NOT mechanism, 2026-09-19):**

1. D perturbations push logits in genuinely DIFFERENT DIRECTIONS, not just different amounts

(3/4 models significant, Z=2.9-5.8, permutation-validated against constraint null).
2. Direction-transfer meta-r (0.51-0.83) is algebraically expected (R21 tautology),
not an independent predictive finding. The underlying D-spread IS real.
3. Cross-model direction prediction: all NS at n=15 (underpowered, not interpretable).
All within-D (same code position), residual-based, and permutation-validated.

**COPY CONTROL — GRADIENT IS SURFACE, NOT COMPUTATION (2026-09-19):**
Qwen3-1.7B on literal assignments (x=5): gap=0.403 [0.288, 0.516], Perm Z=7.9.
Expression gap=0.452. H_surface PASSES (diff=0.049, within 0.15 threshold).
H_compute FAILS (ratio=0.89, not < 0.50). The gradient does NOT require
computation — removing all arithmetic preserves 89% of the effect. This is
pure SURFACE/POSITION sensitivity. Running on remaining 4 models.

**LOCUS CONFOUND DISCOVERY (2026-09-19):**
Cross-group interaction (A/B/C/D) is primarily POSITIONAL (5/8 negative type effect).
Matched-pair test: same operation at different position = same as random cross (diff < 0.06).
BUT within-D direction structure IS genuine (position constant within D).

**Non-monotonic scaling:** Peak fragility at medium scale. Scale-dependent D-coherence:
SmolLM2 135M D=0.71 -> 360M D=0.18 -> 1.7B D=0.44. int_cast is the primary diverger.

**R21 ADVERSARIAL REVIEW — MAJOR CORRECTIONS (2026-09-19):**
1. ATTENUATION RATIO 0.79-1.01: single cell factor reproduces A-D gap. Inert appends
predict rewrite orderings as well as other rewrites do (8/8). "Not predictable" → "less reliable".
2. INTERACTION EXISTS AMONG INERTS ALONE: AB vs C (no D) significant in 7/8. Comment-vs-
statement within A+B significant in 7/8. Declared ABCD not the natural axes.
3. D-COHERENCE OVERCLAIMED: "anti-correlated" → uncorrelated (CIs include 0); "arithmetic
identities" → cluster includes parens; "cond_true = control flow" → SmolLM2-1.7B only,
driven by *1/÷1 identity cells. parens/int_cast coupling may be space-token deletion.
4. MULTIPLICATIVE = first-order Taylor (small-angle regime). Content is in the 12-25% residual.
5. Phi residual IS organized (comment-vs-statement p=0.002), just not along ABCD.
6. No rho on n=40 without CI; no cluster label without partition test (process rule).

**After R21 — what survives cleanly:**

- Gradient is REAL (7+ models, perm-validated, copy-control confirmed)
- Gradient is about surface context features, not computation or semantic type
- Cell fragility is completely model-specific (cross-model rho ~ 0)
- Residual direction structure is real (3/4) but small (12-25% of total)
- Direction divergence predicts pairwise transfer failure (5/6)
- Cross-model prediction fails (direction patterns model-specific)

**This session — new analyses (2026-09-19 continuation 2):**
1. **D-GROUP CROSS-MODEL STRUCTURE (8 models):** Within-D rho 0.169-0.712. Cross-model D-pair
consistency: 0/28 significant. No D-perturbation consistently most anomalous. D-coherence does
NOT predict residual gap (rho=+0.05, p=0.91). Raw gap does NOT predict residual (rho=-0.11).
2. **Tokenization verification:** Confirmed parens/int_cast both delete space token before operand.
Qwen3-0.6B has parens↔int_cast rho=0.18 (outlier vs 0.53-0.80 for all others) despite same
tokenizer. Instruct tuning may explain the decorrelation.
3. **Cell rank distribution:** Mean rank change = 13.3 = random expectation (13.3 for n=40).
Max rank change = 39/40 (`1**5`). Even most stable cells change by 14+ positions.

4. **Fable R21 adversarial review** (launched, 3-round): 2/6 tautological, 2/6 underpowered,
1/6 inflated, 1/6 real (locus confound). All corrections applied to STATE.md.
5. **Qwen3-0.6B-Base kill experiment RUNNING** (fp32 CPU, ~10 min) to resolve instruct confound.
6. **Locus-crossed design specified** (scratchpad): 6 types × 3 positions × 40 cells.

**Continuation 3 — zero-cost analyses and copy control (2026-09-19):**

7. **D-PAIR COUPLING CHECK (fixed, 8 models):** parens-int_cast top-3 in 5/8 confirmed
(rank 1-7/15). BUT coupling is NOT space-token-specific: in 3/8 models, int_cast-add_zero
is stronger than parens-int_cast (despite add_zero preserving the space token). The coupling
tracks syntactic proximity (lightweight wrapping), not tokenization artifacts.

8. **CROSS-MODEL CELL FRAGILITY ANALYSIS (8 models, zero-cost):**
- Cross-model rho = -0.022 [range: -0.494 to +0.348]. CONFIRMED model-specific.
- ANTI-CORRELATED PREDICTORS: double-operator expressions (// % **) are maximally fragile
in SmolLM2-1.7B (rho=0.71) but maximally robust in Qwen3-0.6B (rho=-0.56) and
CodeGen (rho=-0.49). Same feature, opposite effect.
- Answer digit: Qwen3-1.7B rho=-0.48 (low digits fragile), Phi rho=+0.48 (high digits fragile).
- Within-digit ICC: 0.06 (SmolLM2-1.7B, expr-driven) to 0.44 (Qwen3-1.7B, digit-driven).

9. **TOKENIZER SEGMENTATION CHECK (zero-cost):** SmolLM2 and Qwen3 have IDENTICAL
tokenization of all 40 expressions (7 tokens each, same token splits). Yet SmolLM2-1.7B
has rho=+0.71 with double-operators while Qwen3-0.6B has rho=-0.56. StableLM, CodeGen,
Phi produce CONSTANT token counts (all expressions same length). **Fragility is a property
of learned weights, not the tokenizer.** Same tokens in → opposite fragility out.

10. **COPY CONTROL — SmolLM2-1.7B:** Gap=0.386 [0.261, 0.527], Perm Z=7.5. Accuracy 100%.
H_surface PASS (diff=0.105). H_compute FAIL (ratio=1.37 — LARGER than expression gap).
Removing arithmetic makes SmolLM2-1.7B MORE sensitive to headers. 2/2 models confirm
gradient is surface sensitivity. StableLM running.

11. **POSITION vs CONTENT (zero-cost, 7 models):** Perturbations at the SAME POSITION
but with different tokens (mean rho=0.705) are MORE correlated than perturbations with
IDENTICAL tokens at different positions (mean rho=0.530). Position wins 6/7, content 0/7.
Gap = +0.175. Behavioral sensitivity is organized by WHERE modifications are, not WHAT they
contain. After-pairs (0.803) > before-pairs (0.548) — position effect strongest near assignment.

12. **SAME-LINE LOCUS (zero-cost, 7 models):** Same-line inerts (a_whitespace, b_semicolon)
are +0.070 more D-correlated than different-line inerts. 7/7 positive, 2/7 significant.
Small but consistent. The dominant axis is before/after, not same-line/different-line.

13. **COPY CONTROL — StableLM-2-1.6B:** Gap=0.193 [0.094, 0.315], Perm Z=3.9. Accuracy 100%.
H_surface PASS (diff=0.106). H_compute FAIL (ratio=0.65). Third admissible model.
Copy/expr ratio=65% — lowest, but still well above H_compute 50% threshold.
3/3 admissible models from 3 families confirm gradient persists on literals.

14. **INSTRUCTION TUNING AMPLIFIES THE GRADIENT (Qwen3-0.6B base vs instruct):**
IT selectively reshapes correlations: A<->C UP (0.410->0.503, learns inerts are "same kind"),
A<->D DOWN (0.586->0.301, becomes more type-discriminative), D<->D DOWN (0.394->0.169).
Gap AMPLIFIED 1.5x (0.324->0.489). IT makes models MORE sensitive to perturbation type.
CAUTION: single model-pair, needs replication.

15. **POSITION SHIFT MECHANISM TEST — NULL (zero-cost, 7 models):** Absolute token-count

shift does NOT predict C-group pair correlation. Grand r=0.010, p=0.918 (105 pooled pairs). 5/7 models negative. SmolLM2-1.7B highest C pair (rho=0.875) has LARGEST shift diff (4 tokens) — opposite of prediction. The position effect is QUALITATIVE (before vs after in causal attention window), not QUANTITATIVE (how far the assignment shifts). Mechanism: causal attention asymmetry — before-perturbations are attended to by the assignment, after-perturbations are invisible to it.

16. **SPACE-TOKEN CONFOUND — DISMISSED (zero-cost, 7 models):** R21 flagged parens/int_cast share space-token deletion, top-3 D pair in 5/8 models. Test: Jaccard similarity of token-level changes vs behavioral D-pair rho. Grand r=0.094, p=0.340 (n=105). NULL. Critical control: add_zero/zero_plus have IDENTICAL token changes (Jaccard=1.0) but behavioral rho ranges 0.023-0.777 across models. If tokenization drove D-coherence, this pair should always top-correlate. It doesn't. One exception: Qwen3-1.7B r=0.523 (p=0.045). Space-token confound is model-specific at most, not a general threat.

**Continuation 4 — R22 corrections and magnitude asymmetry (2026-09-19):**

17. **FABLE R22 ADVERSARIAL REVIEW (3 round):** Claim 1 (fragility-is-learned) CONFIRMED WITH QUALIFIER — narrow to "token segmentation doesn't predict." Claim 2 (copy=surface) CONFIRMED WITH DESIGN CONCERN — ratio > 1 needs addressing. Claim 3 (syntactic wrapping) NEEDS REVISION — "wrapping" is unoperationalized. 4 corrections applied below.

18. **R22 CORRECTION 1 — TOKEN IDs VERIFIED:** SmolLM2 (49K vocab) and Qwen3 (152K vocab) are DIFFERENT tokenizers with only 26% vocab overlap and different IDs. But all 40 expressions produce identical decoded segmentation. Claim sharpened: "same token boundaries, different token IDs, opposite fragility." (Post-hoc flag: double-operator feature was data-mined, not pre-specified.)

19. **R22 CORRECTION 2 — RATIO BOOTSTRAP CIs:** All 3 models: ratio CI includes 1.0. Qwen3: 0.89 [0.64, 1.14]. SmolLM2: 1.37 [0.93, 1.87]. StableLM: 0.65 [0.31, 1.05]. Gaps INDISTINGUISHABLE at 95%. SmolLM2 ratio>1 is NOT significant — "computation-as-shielding" interpretation unsupported. Binary H_surface/H_compute thresholds DROPPED in favor of CI overlap.

20. **R22 CORRECTION 3 — D COUPLING:** "syntactic wrapping" replaced with precise statement: space-token deletion ruled out (3/8 violate, 6/8 wrong-direction boundary). Replacement mechanism untested — could be edit distance, identity-operation semantics, or modification position. DO NOT name a replacement without evidence.

21. **PERTURBATION MAGNITUDE ASYMMETRY (zero-cost, 8 models):** Cross-model rho for perturbation magnitudes = +0.397 [range: -0.17 to +0.77]. SUBSTANTIALLY SHARED. Compare cell fragility: -0.022. The multiplicative model d = f[i] * m[j] decomposes into one partially universal factor (which change types matter — shared across models) and one completely idiosyncratic factor (which cells are vulnerable). Most consistent pert: c_desc_comment (rank 23-24 in all 8). Least consistent: d_temp_var (rank 1-21). Group ordering: C (before-position) always weakest. Qwen3 has D > A (rewrites more disruptive than inerts); all others have A > D.

22. **FEATURE REGRESSION (zero-cost, 8 models):** Linear regression R2=0.41-0.84 within each model. Zero features have consistent sign across all 8 models. Not one. The fragility landscape is well-structured WITHIN each model but completely unpredictable

ACROSS models. Same-family consistency also absent: SmolLM2-135M vs 360M rho=-0.12,
Qwen3-0.6B vs 1.7B rho=+0.03.

23. **COPY CONTROL — Phi-1.5 (SERIES COMPLETE):** Gap=0.197 [0.115, 0.281], Z=3.83.
Accuracy 100% but P(digit)=0.001 → inadmissible by confidence criterion. H_surface PASS
(diff=0.020). H_compute FAIL (ratio=0.91). 5/5 models tested, ALL H_surface PASS.
3 admissible from 3 families. Copy control series COMPLETE.

24. **DIRECT TRANSFER PREDICTION TEST (zero-cost, 8 models, 28 pairs):**
- Cell vulnerability transfer: rho = -0.022 +/- 0.227. ZERO.
- Perturbation profile transfer: rho = +0.326 +/- 0.171. PARTIAL.
- Within-family best: Qwen3 0.6B->1.7B profile rho=0.52, SmolLM2 within-family 0.47-0.49.
- Cross-family worst: Qwen3-1.7B->CodeGen rho=-0.05 (ANTI-correlated).
- CodeGen is a profile outlier: high transfer with SmolLM2 (0.39-0.51) but near-zero
with Qwen3 (-0.05 to +0.005). Architecture-specific profile clusters.
ALIGNMENT IMPLICATION: you can partially predict WHICH TYPES of changes matter
(~33% shared perturbation hierarchy), but CANNOT predict WHICH INPUTS are affected
(~0% cell fragility transfer). This is why behavioral transfer fails.

25. **CodeGen-350M COPY CONTROL (supplementary):** Gap=0.241 [0.163, 0.337], Z=4.5.
Accuracy 70%, P(digit)=0.000 → NOT admissible. Gradient exists but model struggles
with literal digit prediction. H_surface PASS (diff=0.077). 5/5 copy control done.

26. **SCALING ANALYSIS: WITHIN-FAMILY vs CROSS-FAMILY TRANSFER (zero-cost, 8 models):**
- Within-family magnitude transfer: rho = 0.678 ± 0.091 (4 pairs: 3 SmolLM2, 1 Qwen3)
- Cross-family magnitude transfer: rho = 0.350 ± 0.260 (24 pairs)
- Within-family fragility transfer: rho = 0.028 ± 0.095 (near ZERO, same as cross-family)
- Cross-family fragility transfer: rho = -0.030 ± 0.241 (ZERO)
- No scaling relationship: param distance does NOT predict transfer rho (r=-0.165, p=0.40)
- A-group and D-group profile transfer nearly identical (0.042 vs 0.035) — no group effect
- Per-model factor asymmetry (mag_xfer - frag_xfer) is UNIVERSAL: 0.13-0.59 across all 8
- Qwen3-1.7B is magnitude transfer outlier (lowest at 0.174, all others > 0.29)
IMPLICATION: Architecture determines perturbation hierarchy (within-family 0.68 >> cross 0.35)
but does NOT determine input vulnerability even within the same architecture. The fragility
fingerprint is learned independently at each model scale, not inherited from architecture.

27. **SmolLM2-1.7B-Instruct KILL EXPERIMENT (running):** Replicating Qwen3-0.6B instruction
tuning effect. SmolLM2-1.7B base gap = 0.281. If instruct shows gap >> 0.281, instruction
tuning amplification generalizes beyond Qwen3.

28. **QWEN3 IS A MAGNITUDE-TRANSFER OUTLIER (zero-cost, existing data):**
- Qwen3-0.6B mean cross-family magnitude transfer = 0.289
- Qwen3-1.7B mean cross-family magnitude transfer = 0.084 (LOWEST of all 8)
- Within-Qwen3 family: rho = 0.714 (highly consistent internally)
- Qwen3's perturbation ranking is qualitatively DIFFERENT:
- d_temp_var: ranked #1-2 in Qwen3, #16 median in others
- b_dead_var: ranked #18 in Qwen3-1.7B, #2 median in others
- c_pass_before: ranked #3 in Qwen3-1.7B, #19 median in others
- Both Qwen3 models are instruction-tuned. All other models are base.
- PREDICTION (now tested): If SmolLM2-Instruct magnitude ranking shifts toward Qwen3's

pattern, then instruction tuning reorganizes perturbation sensitivity.

- **RESULT (item 29):** Qwen3-0.6B-Base has rho=0.905 with Qwen3-1.7B-Instruct.

ARCHITECTURE drives magnitude ranking, NOT instruction tuning.

29. **QWEN3 BASE vs INSTRUCT MAGNITUDE TEST (zero-cost, decisive):**

- Qwen3-0.6B-Base vs Qwen3-1.7B-Instruct: rho = 0.905 (near-perfect agreement)
- Qwen3-0.6B-Base vs Qwen3-0.6B-Instruct: rho = 0.737 (strong)
- Qwen3-0.6B-Base vs non-Qwen3 bases: mean rho = 0.186 (low, same as Instruct's 0.285)
- CONCLUSION: Qwen3's perturbation magnitude hierarchy is ARCHITECTURE-DETERMINED.

Instruction tuning has two separable effects:

(a) Magnitude ranking: UNCHANGED by instruction tuning (architecture sets it)

(b) A-D gap: AMPLIFIED 5.6x by instruction tuning (separate mechanism)

- Top rank discrepancies between Base and Instruct: c_pass_before (±13 ranks),

c_dead_var_before (±13), d_add_zero (±11). These are the perturbations most

affected by instruction tuning, but they're small relative to the architecture

signature.

30. **INSTRUCTION TUNING EFFECT ON MULTIPLICATIVE FACTORS (zero-cost, Qwen3-0.6B):**

Group-specific amplification from Base→Instruct:

- A (inert): 0.98x (UNCHANGED)
- B (inert append): 0.94x (~unchanged)
- C (before-position): 1.42x (INCREASED — more sensitive)
- D (rewrites): 0.69x (REDUCED — less sensitive)
- Overall: 0.77x (distances shrink)

Fragility (cell) correlation Base→Inst: rho=0.333 (p=0.036). Weak but significant.

Magnitude (pert) correlation Base→Inst: rho=0.737. Strong (architecture).

KEY INSIGHT: Instruction tuning reduces D absolute sensitivity by 31% while

INCREASING the profile-based gap. The Spearman metric captures CONSISTENCY of

differentiation across cells, not absolute magnitude.

31. **GAP MECHANISM DECOMPOSITION (zero-cost, Qwen3-0.6B Base vs Instruct):**

| Component | Base | Instruct | Change |
|---|---|---|---|
| Within-A rho | 0.910 | 0.791 | -0.119 |
| A-D cross rho | 0.586 | 0.301 | -0.284 |
| Within-D rho | 0.394 | 0.169 | -0.225 |
| Gap (AA-AD) | 0.324 | 0.489 | +0.165 |

70% of gap increase from A-D cross-rho dropping, 30% from within-A dropping.

MECHANISM: Instruction tuning makes D perturbations behave MORE IDIOSYNCRATICALLY.

Each rewrite affects cells in its own distinct pattern (within-D coherence drops 2.3x).

The gap increases NOT because inerts become more consistent but because rewrites

become more DIVERSE in their cell-level effects.

32. **GAP IS FUNDAMENTALLY A D-COHERENCE MEASURE (zero-cost, all 9 model variants):**

Across all 9 models (7 base + 2 instruct), what drives the gap?

- Gap vs Within-A: rho=-0.467 (NS). Within-A is always high (>0.67). DOESN'T predict gap.
- Gap vs A-D cross: rho=-0.850 (p=0.004). Strong negative. AD DRIVES the gap.
- Gap vs Within-D: rho=-0.867 (p=0.002). Strong negative. DD DRIVES the gap.

Within-group ordering is nearly universal: A ≈ B > C ≈ D. Inerts always cohere.

Base models: mean DD=0.482, mean gap=0.268.

Instruct models: mean DD=0.197, mean gap=0.471. 2.5x DD collapse.

INTERPRETATION: The gap measures how DIVERSELY meaning-preserving rewrites affect different cells. High gap = each rewrite is an individually distinct operation on the model's behavior landscape. Low gap = all rewrites do roughly the same thing. Instruction tuning AMPLIFIES rewrite diversity, making each semantic rewrite type individually distinct. This means alignment properties measured under one type of rewrite (e.g., paraphrasing) won't predict behavior under a different type.

33. **FABLE R23 ADVERSARIAL REVIEW — DEVASTATING (2026-09-19):**

VERDICT: "Nothing added since R22 survives as a new finding."

Key corrections applied:

- Profile transfer (0.326) carries +0.008 cell-specific content → NOT a separate test
- "ZERO transfer" → "small mean, large spread" (CI [-0.09, +0.14])
- Magnitude +0.397 → 0.170 after group means → 0.100 without C → mostly C-group floor
- "Alignment testing cannot generalize" → OUT OF SCOPE (was a 4-token header effect)
- 5.6x instruct effect → 1.5x like-for-like (definition artifact)
- "FRAGILITY IS LEARNED NOT TOKENIZED" → "Token segmentation does not predict ordering"
- Bold "ALL H_compute FAIL" contradicted by deprecation → removed
- Effective n ≈ 6 operator strata, not 40 cells

DIRECTIVE: Stop slicing existing 40×24 matrices. Build the balanced cell set (R21 precondition: n≥60, no identity expressions, operator-balanced) before any new cross-model claim.

34. **SmolLM2-1.7B-Instruct COMPLETE — INSTRUCTION TUNING DOES NOT GENERALIZE:**

- Gap = 0.251 [0.170, 0.339], Z=3.2. Accuracy 94.4%, P(digit)=0.931. ADMISSIBLE.
- SmolLM2-1.7B Base gap = 0.281. Instruct gap = 0.251. **Ratio: 0.89x (DECREASES).**
- CIs heavily overlap. Instruction tuning shows NO gap amplification in SmolLM2.
- Group amplification: A=1.92x, B=2.11x, C=2.75x, D=2.65x — ALL increase uniformly.
- Contrast with Qwen3: A=0.98x, D=0.69x (selective D reduction → gap increase).
- Cross-variant correlations: fragility rho=0.689 (strong), magnitude rho=0.883 (very strong).
- Qwen3 cross-variant fragility: 0.333 (weak). SmolLM2 preserves its fingerprint 2x better.

CONCLUSION: Instruction tuning's effect on the gap is ARCHITECTURE-DEPENDENT. Qwen3 amplification (1.5x) does NOT generalize to SmolLM2 (0.89x).

| | Qwen3-0.6B | SmolLM2-1.7B |
|---|---|---|
| Base gap | 0.324 | 0.281 |
| Instruct gap | 0.489 | 0.251 |
| Ratio | 1.5x | 0.89x |
| D amplification | 0.69x | 2.65x |
| Frag rho B/I | 0.333 | 0.689 |

35. **MEANING-CHANGE TRANSFER TEST (Qwen3-1.7B, Group E, fp32 CPU):**

Group E = genuinely meaning-CHANGING perturbations: e_plus_one, e_minus_one, e_times_two, e_negate, e_reassign, e_wrong_const. Same 40 cells, two surfaces.

Does sensitivity to inert additions predict sensitivity to meaning changes?

- Inert (A+B) → E: rho=0.261 (p=0.104) — NOT SIGNIFICANT.
- D (rewrites) → E: rho=0.536 (p<0.001) — SIGNIFICANT.
- A → E: rho=0.345 (p=0.029) — marginal.
- Inert → D: rho=0.568 (p<0.001) — still strong (consistency check).

KEY: D sensitivity predicts meaning-change sensitivity but inert sensitivity DOES NOT.
The A-D gap captures proximity to genuine behavioral vulnerability. D is qualitatively
closer to actual semantic changes. e_wrong_const (x=42) has rho=nan (constant cross-surface
distance — no cell variation when output is fixed).
LIMITATION: Single model. Needs replication on SmolLM2, StableLM before claiming generality.
NOTE: This is the first test where group types are COMPARED across a semantic boundary.
All prior work stayed within meaning-preserving perturbations.

36. **MEANING-CHANGE TRANSFER REPLICATION (SmolLM2-1.7B, Group E, fp32 CPU):**
REPLICATION PARTIALLY SUCCEEDS — pattern differs from Qwen3:

| Transfer | Qwen3-1.7B | SmolLM2-1.7B |
|---|---|---|
| Inert (A+B) → E | 0.261 (NS) | **0.514 (p<0.001)** |
| D → E | 0.536 (p<0.001) | **0.727 (p<0.001)** |
| A → E | 0.345 (p=0.029) | 0.504 (p<0.001) |
| Inert → D | 0.568 (p<0.001) | 0.800 (p<0.001) |

UNIVERSAL: D→E > Inert→E in both models (Δ=0.213 SmolLM2, Δ=0.275 Qwen3).
NOT UNIVERSAL: Inert→E is NS in Qwen3 but sig in SmolLM2. SmolLM2 has higher
baseline correlations everywhere (Inert→D 0.800 vs 0.568), so inert and D are less
separable as predictors. The A-D gap is sharper in Qwen3 (higher discrimination).
Per-pert: additive shifts (e_plus_one, e_minus_one) and reassignment well predicted
by inert (rho=0.518-0.727); multiplicative (e_times_two, 0.215 NS) and negation
(e_negate, -0.247 NS) are not.
CONCLUSION: D is always a better predictor of meaning-change sensitivity than inert.
Whether inert itself reaches significance depends on the model's baseline A-D correlation.

37. **BALANCED CELL SET v3 — FABLE-REVIEWED, RUNNING (2026-09-19):**
R21/R23 mandated: build operator-balanced set before any new cross-model claims.
**Design (v3, post-review):**
- 60 primary cells: + (15), - (15), // (15), % (15)
- 9 appendix cells: * (6), ** (3) — not in stratum-mean comparisons
- ALL operands 1-9 (no double-digit tokenization confound)
- Identity filter: "answer readable without arithmetic step" — excludes a-a, a//a,
a%b with a<b, a//1, a%1, a%a, etc. Zero identities in final set.
- // floor-zero (a<b) capped at 3, labeled sub-stratum
- % answer-0 capped at 3
- 24 perturbations (same A/B/C/D groups as original 40-cell)
- 3312 forward passes per model (~4.4 min fp32 CPU)

**Fable review findings (R24):**
- v2 identity filter incomplete (% with a<b was identity in old set)
- Double-digit operands create tokenization confound (Qwen3=2 tokens, SmolLM2=1)
- Both fixed in v3. Pre-registered: primary 60-cell core for main analysis,

69-cell all + 60-cell primary + residual-after-stratum-means as three views.

- Power ~0.72 for rho=0.3 at n=69. Estimate with CI, not test.

- Commuted pairs kept as within-operation error term.

**Running:** Qwen3-1.7B-Base first (reference), then sequential models.

Script: `experiments/run_balanced_kill.py`

**Qwen3-1.7B-Base COMPLETE (2026-09-19):**

- Gap = 0.500, CI [0.411, 0.588], Perm Z = 4.4 (old 40-cell: 0.452)

- Residual gap (stratum means removed) = 0.462 — 92% of gap survives

- Primary-only gap (60 cells) = 0.524

- eta2_operator = 0.394, eta2_answer_digit = 0.121

- Multiplicative model R^2 = 0.85 (pert=67%, cell=18%, interaction=15%)

- Cell effective dimensionality = 1.6, perturbation = 3.1

- Fragility inversely correlates with gap (rho=-0.316, p=0.008)

- d_zero_plus is anti-correlated with group A (gap=0.933); d_cond_true is A-like (gap=0.178)

- Per-operator A-to-D profile transfer: //=+0.623, *=+0.229, +=−0.013

- Perturbation magnitudes old vs new: rho=0.989 (instrument validated)

**SmolLM2-1.7B COMPLETE:**

- Gap = 0.275, CI [0.202, 0.362], Perm Z = 4.3

- Old 40-cell gap was 0.281 (delta -0.006, stable)

- Residual gap = 0.389 (141% of raw — INCREASES after removing operator means)

- eta2_operator = 0.687, eta2_answer_digit = 0.408

- Accuracy = 87.6%, admissible

- Stratum means 15-80x larger than Qwen3 (SmolLM2 much more perturbation-sensitive)

**CROSS-MODEL (Qwen3 vs SmolLM2, balanced 69-cell):**

- Cell fragility rho = +0.108 (p=0.38, NS) — model-specific (old: +0.125 same pair)

- Pert magnitude rho = +0.017 (p=0.94) — was +0.035 this pair (old +0.397 was 5-model mean)

- Residual fragility rho = +0.183 (p=0.13, NS)

- Multiplicative residual rho = -0.008 (NS)

- Only Group C (semantic) magnitude transfers: rho = +0.943, p=0.005 (n=6, same in old+new!)

- SmolLM2 residual gap INCREASES (+41%) vs Qwen3 DECREASES (-8%)

**FULL 10-MODEL REANALYSIS (old 40-cell) reveals hierarchical transfer structure:**

- Magnitude within-family mean +0.700 (n=9), cross-family +0.306 (n=36), p<0.0001 (MW)

- Fragility within-family mean +0.134 (n=9, NS vs cross), cross-family -0.007 (n=36)

- Same-scale base/instruct: mag +0.810, frag +0.511 (IT partially preserves fragility)

- Diff-scale same family: mag +0.669, frag +0.027 (SCALING DESTROYS FRAGILITY)

- Qwen3 family mag: +0.714 to +0.905. SmolLM2 family mag: +0.770 to +0.883

- Phi-SmolLM2-1.7B fragility: -0.491 (p=0.001, ANTI-correlated across families)

**ALIGNMENT IMPLICATION:** Red-teaming types-of-attacks transfer across model scales;

specific failure-input identity does NOT. IT preserves vulnerable inputs partially; scaling wipes them.

SmolLM2-360M balanced: gap=0.244, acc=69.2% (NON-ADMISSIBLE), residual=0.471 (+93% increase, same SmolLM2 pattern)

eta2_operator=0.854 (scales inversely with model size: 360M→0.854, 1.7B→0.687, Qwen3-1.7B→0.394)

**3-MODEL BALANCED CROSS-ANALYSIS:**

- Within-family fragility (SmolLM2 1.7B vs 360M): raw +0.496, residual +0.189 (operator-driven)

- Cross-family (Qwen3 vs SmolLM2-360M): raw -0.257 (ANTI-correlated!), residual +0.161

- ALL pairs converge to residual ~+0.17 after operator mean removal → small universal component

**FOUR-LEVEL TRANSFER HIERARCHY (old 10-model + balanced 3-model):**

L1: Operator type — partially shared across families (removed by stratum means)

L2: Within-operator cell difficulty — weakly shared (rho~0.21, ONLY universal component)

L3: Perturbation magnitude ordering — family-specific (within +0.740, cross ~0)

L4: Cell x perturbation interaction — unique per model (within +0.187, cross ~0)

Magnitude profile dimensionality: 2.1 (PC1=68%, separates Qwen3 from SmolLM2)

Fragility profile dimensionality: 4.1 (no dominant structure)

**FORMAL 4-LEVEL VARIANCE DECOMPOSITION (log-space, balanced 69-cell):**

Qwen3-1.7B: operator 6.7%, perturbation 67.0%, cell-within-op 11.6%, interaction 14.7%

SmolLM2-1.7B: operator 34.4%, perturbation 40.5%, cell-within-op 10.3%, interaction 14.9%

SmolLM2-360M: operator 35.0%, perturbation 39.8%, cell-within-op 7.0%, interaction 18.3%

→ Qwen3 = perturbation-dominated (HOW you perturb matters); SmolLM2 = operator-dominated (WHAT you compute matters)

→ Cross-family transfer fails because models organize computation differently

→ Operator rho: within +0.600, cross -0.657 to +0.086 (families DISAGREE on operator difficulty)

→ Cell-within-op rho ~+0.21 for ALL pairs = arithmetic-difficulty universality

→ Per-stratum universality: subtraction +0.482, addition +0.307; complex operators (%, //) no agreement

**Qwen3-0.6B-Base COMPLETE (balanced 69-cell):**

- Gap = 0.271, CI [0.187, 0.354], Z=2.3
- Residual gap = 0.427 (+57% increase — same pattern as SmolLM2 models)
- Primary-only gap = 0.283
- eta2_operator = 0.653, eta2_answer_digit = 0.093
- Accuracy = 97.2%, admissible
- Variance: operator=5.9%, perturbation=75.3%, cell=5.7%, interaction=13.1%

→ Even MORE perturbation-dominated than Qwen3-1.7B (75% vs 67%)

**UPDATED 4-MODEL CROSS-ANALYSIS (2 within-family + 4 cross-family pairs):**

| Pair | Op | Cell | Pert | Int | Family |
|---|---|---|---|---|---|
| Qwen3-0.6B vs Qwen3-1.7B | -0.257 | +0.072 | **+0.937** | +0.133 | WITHIN |
| SmolLM2-1.7B vs SmolLM2-360M | +0.600 | +0.211 | **+0.740** | +0.187 | WITHIN |
| Within mean | +0.171 | +0.142 | **+0.838** | +0.160 | |
| Cross mean (4 pairs) | -0.029 | +0.135 | **-0.072** | +0.039 | |

KEY: Perturbation magnitude is SHARPLY family-specific (+0.838 within, -0.072 cross).

Cell-within-operator ~+0.14 for BOTH within and cross → universal arithmetic difficulty.

Qwen3 within-family pert rho = +0.937 (near-identical perturbation profiles across scales).

SCALING FINDING: Residual gap INCREASES for all models except largest (Qwen3-1.7B):

Qwen3-1.7B: -8% | Qwen3-0.6B: +57% | SmolLM2-1.7B: +41% | SmolLM2-360M: +93%

→ Smaller models have more operator-level confound masking the underlying gap.

eta2_op scales inversely: 360M=0.854, SmolLM2-1.7B=0.687, Qwen3-0.6B=0.653, Qwen3-1.7B=0.394

**FABLE R25 ADVERSARIAL REVIEW — COMPLETE (2026-09-19):**

WITHDRAWN:

- F2 "magnitude rho collapsed +0.397→+0.017": FALSE COMPARISON. Pair was always ~0
(+0.035 old, +0.017 new). The +0.397 was a panel mean driven by Group C floor (R23).
- F3 "only semantic (Group C) transfers": MISLABELED. Group C is PREFIX-POSITION INERT
(comment_before, pass_before, etc.), NOT semantic. Semantic perts are in Group D.
The rho=+0.943 is a token-adjacency/header-buffering effect, not semantic transfer.

MERGED: F1 + F4 are ONE observation (high eta2_op → compressed raw gap; mechanically linked).
DOWNGRADED: F5 between-model gap difference vanishes on residual gaps (CI [-0.09, +0.23]).
SURVIVING: Both gaps positive and replicated to 3 decimals across cell sets. Gap is REAL.
NEW FINDINGS from review:
- N3: Fragility tracks UNCERTAINTY in SmolLM2 (rho=-0.50 with p_answer) but NOT Qwen3 (+0.28).
SmolLM2's high eta2_op is a COMPETENCE effect (weak on //, % strata), not "modularity".
- N4: Group C is structurally different from A/B (prefix position vs suffix). Should not be
pooled as "inert" in any summary — a<->c mixes position with perturbation type.
- N6: Three D perturbations (d_add_zero, d_zero_plus, d_cond_true) reintroduce literal 0 tokens.
Cell set purged zeros but 3/6 D perts put them back. Partial contamination, not fatal.
ACTION ITEMS: (1) Add per-cell predictions to runner output, (2) report gap on argmax-preserving
cells only, (3) relabel Group C everywhere, (4) pre-register Group C ordering for remaining panel.
**Phi-1.5 balanced kill RUNNING** (cell 60/69, 64% accuracy — NON-ADMISSIBLE but diagnostic).
**R26 TOKENIZER CONFOUND TEST — REFUTED:**
Token-count difference (verbose - minimal) is CONSTANT at 4 for ALL 24 perturbations
across ALL 5 tokenizers (Qwen3, SmolLM2, Phi). One exception: c_newline_before = 3 for Qwen3.
Family-specific perturbation magnitude profiles CANNOT be explained by tokenizer differences —
all models see the same token-level input change. The perturbation magnitude hierarchy is
genuinely about how models process identical inputs differently.
**R26 PRE-REGISTRATION (BEFORE Phi-1.5 result seen):**
H1: eta2_op tracks operator competence (predict Phi eta2_op > 0.5 given 64% accuracy)
H2: Pert magnitude family-specific (predict Phi pert rho < +0.2 vs all — TOKENIZER RULED OUT)
H3: Cell-within-op universal ~+0.14 — OPERAND-MAGNITUDE CONFOUND REFUTED:
Per-model residual-vs-operand_max: ALL near zero (-0.116 to +0.004, p>0.34).
Partial correlations identical to raw (controlling for max(a,b) changes nothing).
The universal component is NOT "bigger numbers are harder."
H4: Group C ordering shared (comment < statement < whitespace, effective df ~3)
H5/H6 merged into H1 (mechanical corollaries of competence gradient)
Per-cell records added to runner (R25 N5 action). Hypotheses pre-registered in scratchpad.
**Phi-1.5 COMPLETE (balanced 69-cell, NON-ADMISSIBLE):**
- Accuracy: 65.0%, P(digit) median: 0.0004 (barely assigns probability to correct digit)
- Gap: 0.034, CI [0.006, 0.067] — near zero (old 40-cell was 0.055)
- Residual gap: 0.190 (5.6x increase — most dramatic in entire panel)
- eta2_operator: 0.834 (comparable to SmolLM2-360M's 0.854)
- Variance: op=33.5%, pert=49.6% (intermediate between Qwen3 and SmolLM2)
- All group rhos very high (0.69-0.85) — Phi treats all perturbation types similarly
- A-D gap nearly vanishes (0.851 vs 0.818) — no semantic vs inert distinction
**PRE-REGISTERED H1 CONFIRMED (3 families):** eta2_op inversely scales with accuracy:
| Model | Family | Accuracy | eta2_op |
| Qwen3-1.7B | Qwen3 | 99.1% | 0.394 |
| Qwen3-0.6B | Qwen3 | 97.2% | 0.653 |
| SmolLM2-1.7B | SmolLM2 | 87.6% | 0.687 |
| SmolLM2-360M | SmolLM2 | 69.2% | 0.854 |
| Phi-1.5 | Phi | 65.0% | 0.834 |

**H2 PARTIALLY CONFIRMED (nuance):** Phi pert rho:

- vs Qwen3: +0.155 to +0.238 (NS) — as predicted

- vs SmolLM2-1.7B: +0.484 (p=0.016) — SIGNIFICANT! Unexpected cross-family similarity

- CAVEAT: Both Phi and SmolLM2 have low accuracy — shared pert profile may be

competence confound (confused models produce similar distance patterns regardless of family).

Need admissible cross-family model (StableLM) to resolve.

StableLM-2-1.6B RUNNING. late_twins.py qwen3 consuming 7.5GB (stale, from prior agent).

**StableLM-2-1.6B COMPLETE (balanced 69-cell, NOT ADMISSIBLE):**

- Accuracy: 72.0%, P(digit) median: 0.621 (reasonable but acc<80%)

- Gap: 0.215, CI [0.161, 0.285], Z=2.34 — positive, significant

- Residual gap: 0.173

- eta2_operator: 0.608 (BREAKS H1 monotonicity — lower than SmolLM2-360M despite similar accuracy)

- Operator difficulty: ** > // > + > - > * > % (shares // fragility with SmolLM2)

**TWO-CLUSTER FINDING (6 models, PROVISIONAL pending R26 review):**

Perturbation-level cross-correlations reveal TWO clusters, NOT family-specific profiles:

- QWEN3 CLUSTER (2 models): +0.937 within, near-zero with everything else (+0.017 to +0.042 vs SmolLM2)

- NON-QWEN3 CLUSTER (4 models, 3 families): SmolLM2-StableLM rho=+0.642/+0.654,

Phi-SmolLM2-1.7B=+0.543, Phi-StableLM=+0.457. Moderate-high mutual rho ACROSS families.

This is NOT a competence confound: StableLM (72%) has rho=+0.642 with SmolLM2-1.7B (88%).

The original "cross-family = zero" was a QWEN3-SPECIFIC effect, not universal.

RISK: Only 3 admissible models (2 Qwen3 + 1 SmolLM2). Cannot test admissible non-Qwen3 cross-family.

Fable R26 review IN PROGRESS.

**H1 UPDATE (6 models):** rho(accuracy, eta2_op) = -0.771 (p=0.072).

StableLM anomaly: 72% acc but eta2=0.608 (lower than 360M at 0.854 with 69% acc).

Monotonic H1 WEAKENED to "strong negative tendency with exceptions."

**Admissible-only transfer (unchanged):** within +0.937, cross +0.029. Gap +0.907.

But this is Qwen3-vs-SmolLM2 only (n=3 models, n=1 within pair, n=2 cross pairs).

**Next:** SmolLM2-1.7B-Instruct (IT comparison), then Qwen3-0.6B-Instruct. R26 review pending.

38. **HEADER RELOCATION TEST (Qwen3-1.7B-Base, R22 E1, fp32 CPU, 2026-09-18):**

Moved `# Python code\n` from BEFORE code to AFTER assignment line.

Original verbose: `# Python code\n{before}{assign}\n{after}{query}`

Relocated verbose: `{before}{assign}\n# Python code\n{after}{query}`

| Group Rho | Original | Relocated | Delta |

|---|---|---|---|

| A_A | 0.786 | 0.584 | -0.202 |

| A_B | 0.812 | 0.575 | -0.238 |

| A_C | 0.611 | 0.338 | -0.273 |

| A_D | 0.333 | 0.350 | +0.016 |

| B_B | 0.837 | 0.739 | -0.098 |

| B_C | 0.617 | 0.162 | -0.456 |

| C_C | 0.589 | 0.453 | -0.135 |

| D_D | 0.224 | 0.239 | +0.015 |

| Gap | 0.453 | 0.234 | -0.219 |

HEADER ADJACENCY HYPOTHESIS: REJECTED AS SOLE MECHANISM. Simple adjacency predicted

C_C should INCREASE (freed from header); instead it DECREASED (-0.135). The header in the MIDDLE disrupts ALL correlations, not selectively the adjacent ones. B_C dropped the most (-0.456) because the header now physically separates before and after blocks. KEY: D_D and A_D barely changed (~+0.015). D perturbations rewrite the assignment itself and are independent of header position. The gap halved from 0.453 to 0.234: roughly 50% header effect, 50% genuine A-D structural difference. The residual gap (0.234) matches the 11-bin gap direction (0.359) and the balanced-cell gap (0.500), confirming a real structural component beyond header artifacts.

39. **FABLE R24 ADVERSARIAL REVIEW — MAJOR CORRECTIONS (2026-09-18):**
Two-round review of meaning-change transfer findings. Key corrections:
(a) 16/40 cells (40%) are identity expressions — dominant confound in all prior results.
(b) SmolLM2 Inert->E (0.514) RETRACTED: drops to 0.143 (NS) on non-identity cells.
(c) D->E transfer driven by 2 of 6 D members (add_zero + cond_true) in BOTH models on non-identity cells. Other 4 D members contribute near-zero.
(d) Token-prefix sharing explains the correlation structure: pairs that share more prefix tokens (add_zero/plus_one) correlate highly; prefix-breaking pairs (temp_var/plus_one) do not.
(e) Full-logit cosine vs 11-bin disconnect: in Qwen3, cell-profile cross-readout rho is 0.099 (inert) and -0.084 (D). The full-logit cosine measures formatting geometry, not answer sensitivity, in Qwen3.
(f) BUT: the gap SURVIVES on 11-bin in all 4 models (0.19-0.37). Not just formatting.
(g) E-group has no coherence beyond form twins. Partial E-E rho after removing twins ~0.
RETRACTIONS: SmolLM2 Inert->E; "depends on model" difference (NS); "additive transfers multiplicative doesn't" (prefix confound); "D captures behavioral vulnerability" (no behavioral quantity measured).
SURVIVING: D->E > Inert->E on non-identity cells (0.46/0.39 vs 0.07/0.14), driven by add_zero + cond_true. Consistent with token-prefix sharing, not yet separable from it.

40. **SmolLM2 balanced kill v3 COMPLETE (2026-09-19).**
Gap=0.275, CI [0.202, 0.362], perm z=4.33. 69 cells, 87.6% accuracy, admissible.
Group rhos (full-logit): AA=0.944, AB=0.929, AC=0.757, AD=0.669, DD=0.531.
DD < AD again (universal). Residual gap 0.389 (HIGHER than raw — operator strata absorb some of the gap, so partialling them out increases the A-D difference).
Eta-squared: operator=0.687, answer_digit=0.408.
Compares to Qwen3 balanced (0.500): SmolLM2 lower, consistent with original 40-cell (SmolLM2 0.281, Qwen3 0.452). Both survive on balanced cells.

41. **Prefix-form crossover COMPLETE — Qwen3 (2026-09-19).**
2x2 design: D members (add_zero=`e+0`, zero_plus=`0+e`) x E members (plus_one=`e+1`, one_plus=`1+e`). 80 new forward passes for one_plus, rest from existing data.
Non-identity cells (n=24):
- add_zero -> plus_one: rho=0.634 (same prefix `e + N`, STRONG)
- add_zero -> one_plus: rho=-0.301 (diff prefix, ANTI-correlation)
- zero_plus -> one_plus: rho=0.063 (same prefix `N + e`, WEAK)
- zero_plus -> plus_one: rho=0.428 (diff prefix, MODERATE)
- Diagonal mean: 0.349, off-diagonal mean: 0.063

- E-E rho (plus_one vs one_plus): -0.143 (independent)

**R25 CORRECTION:** The 2×2 is a COLUMN main effect (plus_one transfers, one_plus doesn't), not a diagonal/prefix effect. Interaction NS in both models. `one_plus` is a garden-path column (precedence confound on `* // %` cells). Operator strata reverse the diagonal in Qwen3. "E-E independence" RETRACTED (CI spans zero in Qwen3). See entry 46.

42. **SmolLM2 prefix crossover COMPLETE — signs replicate Qwen3 (2026-09-19).**

Non-identity cells (n=24):

| D \ E | plus_one (e+1) | one_plus (1+e) |
|---|---|---|
| add_zero (e+0) | **0.676** | -0.405 |
| zero_plus (0+e) | 0.390 | -0.159 |

Diagonal mean: 0.258, off-diagonal: -0.007. E-E rho: **-0.470 (p=0.021, SIG)**.

All four signs replicate Qwen3. E-E anti-correlation is stronger and significant.

43. **VARIANCE ANALYSIS KILLS SIMPLE PREFIX STORY (zero-cost, 2026-09-19).**

add_zero has 3.55x (Qwen3) / 4.27x (SmolLM2) more cross-cell variance than zero_plus. The "diagonal > off-diagonal" is dominated by one high-variance entry, not a symmetric prefix-form mechanism. Full D x E table shows d_temp_var REVERSES the pattern in both models. Mean D -> plus_one: +0.311 (p=0.139, NS). Mean D -> one_plus: -0.277 (p=0.191, NS). Neither prefix nor gradient hypothesis survives aggregation over all D members.

ROBUST FINDINGS:

(a) E-E anti-correlation (sig in SmolLM2, -0.470). Sensitivity to `e+1` and `1+e` are anti-correlated. Operand position matters.

(b) add_zero specifically transfers to plus_one (0.634/0.676 cross-model) and anti-transfers to one_plus (-0.301/-0.405). This is additive-position-specific, not a general D property.

(c) Transfer is perturbation-member-specific, not perturbation-group-specific. Individual D member identity determines which E members are predicted, not "D as a group."

44. **11-BIN CROSSOVER REANALYSIS — TOKEN-PREFIX NULL REFUTED (Qwen3, 2026-09-19).**

CRITICAL: The E-E anti-correlation and position-dependent transfer are FULL-LOGIT-SPECIFIC. On 11-bin (answer distribution), the picture completely reverses:

| Cell | Full-logit | 11-bin |
|---|---|---|
| add_zero->plus_one [DIAG] | +0.634 | +0.610 |
| add_zero->one_plus [OFF] | -0.301 | **+0.531** |
| zero_plus->plus_one [OFF] | +0.428 | **+0.710** |
| zero_plus->one_plus [DIAG] | +0.063 | **+0.423** |
| E-E rho | -0.143 | **+0.758 (p<0.001)** |

ALL four entries positive and significant on 11-bin. E-E flips from -0.14 to +0.76. Off-diagonal HIGHER than diagonal (0.620 > 0.517) — gradient hypothesis WINS on 11-bin.

IMPLICATIONS:

(a) The R24 "token-prefix null" (transfer follows prefix, not meaning) is REFUTED on 11-bin. On the answer distribution, all additive perturbations transfer regardless of operand position. The token-prefix pattern existed only in formatting geometry.

(b) Entries 41-43 full-logit findings (member-specificity, E-E anti-correlation, operand position) are RETRACTED as general claims. They describe full-logit formatting effects,

not answer-distribution behavior.
(c) The 11-bin picture is simpler: cells have a common "sensitivity" factor. Both D and E perturbations load on this factor. The gap (AA-AD) measures D-DIVERSITY (how differently each D member modulates this factor), not D-DISCONNECTION from E.
(d) REFRAMING: The gap is real. D->E transfer is also real (on 11-bin). The gap measures internal D diversity, not lack of cross-group transfer.
**R25 QUALIFICATION:** This 11-bin result was on old 40-cell set (violating balanced-v3 mandate). R25 shows the 2×2 column effect (one_plus anomaly) confounds the crossover. SmolLM2 partial replication (entry 45) weakens the "broad transfer" claim. Qwen3 11-bin may also be operator-stratum driven. Needs rerun on balanced v3 with within-operator control.

45. **SmolLM2 11-BIN CROSSOVER REPLICATION — PARTIAL (2026-09-19).**
Core artifact claim CONFIRMED: E-E flips from -0.470 (p=0.021) to +0.124 (NS, p=0.563). Anti-correlation is a full-logit formatting effect in both models.
BUT broad positive transfer does NOT replicate:

| Cell | Full-logit | 11-bin |
|---|---|---|
| add_zero->plus_one [DIAG] | +0.676 | **+0.564** |
| add_zero->one_plus [OFF] | -0.405 | +0.089 (NS) |
| zero_plus->plus_one [OFF] | +0.390 | +0.170 (NS) |
| zero_plus->one_plus [DIAG] | -0.159 | +0.129 (NS) |
| E-E rho | -0.470 | +0.124 (NS) |

Only 1/4 entries significant on 11-bin (add_zero→plus_one, the dominant D member). Qwen3 had 4/4 significant and E-E=+0.758. SmolLM2 has 1/4 and E-E=+0.124.
IMPLICATIONS:
(a) Anti-correlation-as-artifact: CONFIRMED across both models. The sign flip is universal.
(b) Broad positive transfer on 11-bin: QWEN3-SPECIFIC, not universal.
(c) add_zero dominance: The only surviving cross-readout transfer in BOTH models is add_zero→plus_one. This is the highest-variance D member (3.5-4.3x).
(d) The "D-diversity not D-disconnection" reframing needs qualification: on SmolLM2, D→E transfer on 11-bin is weak outside add_zero. The gap still measures D-diversity, but D-diversity doesn't guarantee D→E transfer on the answer distribution.

46. **FABLE R25 ADVERSARIAL REVIEW — DEVASTATING (2026-09-19).**
The 2×2 is a COLUMN main effect, not a diagonal/prefix effect.
Column effect (plus_one − one_plus): +0.65 / +0.82 (CI excl 0 in both models).
Row effect: NS. Interaction: NS (p=0.085 / 0.052, CI includes 0).
`one_plus` (1+e) is a GARDEN-PATH column: anti-correlates with 17/18 inerts in Qwen3 (mean rho -0.44). `1 + 8 // 2` is parsed as precedence override.
Operator strata REVERSE Qwen3 diagonal: within-stratum ad→plu = -0.23 (sign flip!).
SmolLM2 ad→plu survives within-operator (+0.52) but interaction collapses to 0.04.
RETRACTIONS: "prefix form partial mediator" → downgrade; "E-E independence" → retract; "meaning change determines cells" → withdraw; "token-prefix sharing" → narrow to late-edit locality only.
MOST HONEST READING: Edit locality relative to `e` + precedence artifact in `1+e`. Append-after-e edits cohere (rho 0.43-0.66). Meaning change has NO demonstrated role.

CRITICAL GAP: No meaning-preserving late twin (e-0, e*1) ever measured. If these
correlate with e+1 as much as e+0 does, the D→E narrative is dead.
EXPERIMENT DESIGNED: Late-twin disambiguation (6 perts on balanced v3, both readouts).

47. **WITHIN-OPERATOR STRATUM ANALYSIS — GAP SURVIVES AND GROWS (zero-cost, 2026-09-19).**
On balanced v3 (69 cells), tested whether the gap (AA-AD) is operator-stratum artifact.

| Metric | Qwen3 | SmolLM2 |
|---|---|---|
| Raw gap | 0.500 | 0.275 |
| Within-operator residual gap | **0.515** | **0.365** |
| DD < AD within strata | 5/5 | 3/5 |

The residual gap is HIGHER than raw in BOTH models. Operator strata SUPPRESS the gap.
Per-stratum: `-` has largest gap (0.711/0.221), `*` smallest (0.272/0.043).
CRITICAL: d_add_zero and d_zero_plus (the crossover D members) have the LOWEST AD
correlations of all D members (0.068/-0.171 Qwen3). They're the LEAST representative
D members. R25's "operator strata reverse the diagonal" was about these anomalous members
on the old 40-cell set — not representative of the gap as a whole.
d_cond_true has the HIGHEST AD (0.584/0.839). d_temp_var, d_parens, d_int_cast: 0.31-0.39
(Qwen3) / 0.70-0.82 (SmolLM2). The gap is driven by the majority of D members, not outliers.

48. **LATE-TWIN DISAMBIGUATION — MEANING IS DEAD ON 11-BIN (Qwen3, 2026-09-19).**
R25's #1 experiment. 6 append-after-e perts on balanced v3 (69 cells), both readouts.
D (meaning-preserving): e+0, e-0. E (meaning-changing): e+1, e-1, e+2, e+3.
Sanity: kill-data add_zero vs fresh e+0 rho=1.0000 (deterministic).
**Full-logit:** D-D=+0.658, D-E=+0.424, E-E=+0.405. D-D > D-E by +0.234.
Meaning-preserving twins more similar in formatting geometry.
**11-bin:** D-D=+0.591, D-E=+0.644, E-E=**+0.781**. D-D < D-E by -0.053.
**Meaning is IRRELEVANT on answer distribution.** E-E is HIGHEST. Meaning-changing perts
are MORE internally coherent. e+0 correlates MORE with E (0.73-0.83) than e-0 (0.59) on
11-bin. INTERPRETATION: all late-edit perts load on common "surface sensitivity" factor.
Meaning changes AMPLIFY this (E-E > D-E > D-D) via answer-uncertainty increase.
The D->E narrative is DEAD on 11-bin.
**Full-logit bootstrap CI on D-D minus D-E: [+0.082, +0.382]** (excludes zero: meaning
matters on formatting geometry, confirmed). 11-bin bootstrap pending.

49. **AMPLIFICATION GRADIENT ANALYSIS (Qwen3 late-twin reanalysis, zero-cost, 2026-09-19).**
E-E coherence is STRUCTURED by answer-shift direction:
Same-sign E-E (both shift answer same way): mean rho=0.836 (11-bin), 0.543 (FL).
Opposite-sign E-E: mean rho=0.725 (11-bin), 0.267 (FL).
By |value_diff|: 1=>0.847, 2=>0.771, 3=>0.700, 4=>0.749 (nearly monotonic).
Not just "E is noisier" — the noise is structured by answer-shift direction and magnitude.
Confirms amplification mechanism: cells where model is uncertain become more uncertain for
BOTH same-direction perts, creating correlated distance profiles.

50. **SmolLM2 LATE-TWIN REPLICATION — CONFIRMED (2026-09-19).**
Same 828 fwd passes on SmolLM2-1.7B. Sanity: rho=1.0000 vs kill-data add_zero.
**Full-logit:** D-D=+0.704, D-E=+0.468, E-E=+0.541. D-D minus D-E = +0.236.
Bootstrap CI [+0.106, +0.357] (excludes zero: meaning matters on FL, confirmed).

**11-bin:** D-D=+0.365, D-E=+0.349, E-E=+0.415. D-D minus D-E = **+0.015**.

Bootstrap CI **[-0.171, +0.200]** (SPANS ZERO: meaning is IRRELEVANT on answer dist).

REPLICATION TABLE:

| | Qwen3 FL | Qwen3 11b | SmolLM2 FL | SmolLM2 11b |
|---|---|---|---|---|
| D-D | +0.658 | +0.591 | +0.704 | +0.365 |
| D-E | +0.424 | +0.644 | +0.468 | +0.349 |
| E-E | +0.405 | +0.781 | +0.541 | +0.415 |
| D-D minus D-E | +0.234 | -0.053 | +0.236 | +0.015 |

Both models: meaning matters on FL (CI excludes zero), meaning irrelevant on 11-bin.

SmolLM2 amplification weaker (E-E=0.415 vs Qwen3 0.781) but ordering preserved.

51. **CROSS-POSITION TRANSFER (zero-cost reanalysis, both models, 2026-09-19).**

Reanalyzed balanced kill data: A (after), B (novel after), C (before), D (rewrites).

Qwen3 (full-logit): A-A=0.762, C-C=0.458, A-C=0.557, A-D=0.262, C-D=0.276.

SmolLM2 (full-logit): A-A=0.944, C-C=0.805, A-C=0.757, A-D=0.669, C-D=0.626.

KEY: A-A > A-C in both (bootstrap CI excludes zero). "After" perts cohere within position.

BUT: C-C < A-C in Qwen3 (!), C-C marginal over A-C in SmolLM2. "Before" perts less cohesive.

A-D ≈ C-D in both: rewrites are equally low from both positions. Gap doesn't depend on

reference position. D diversity (DD << AD) is confirmed as the gap's structural cause.

52. **TRIVIAL PERT INFLATION TEST — FALSIFIED (zero-cost, 2026-09-19).**

Dropped trivial A (empty, whitespace, newline) from gap computation.

Qwen3: gap 0.500 => 0.451 (10% drop). SmolLM2: 0.275 => 0.242 (12% drop).

A-D unchanged (0.264 vs 0.260 Qwen3). Gap shrinkage comes from A-A dropping,

not A-D changing. B group gap is similar (0.522 Qwen3, 0.261 SmolLM2).

The gap is ROBUST to perturbation selection within inerts.

53. **ADVERSARIAL SELF-REVIEW — KEY ATTACKS ON LATE-TWIN (2026-09-19).**

(a) D-group has ONLY 1 D-D pair (e+0 ~ e-0). And e+0/e-0 are nearly identical (both add

zero). With 1 pair vs 8 D-E and 6 E-E pairs, D-D estimate has massive variance.

RESPONSE: Bootstrap CI for SmolLM2 11-bin spans zero [-0.171, +0.200], confirming low power.

Correct claim: "we FAIL TO DETECT meaning effect on 11-bin" (null), not "meaning is dead."

FIX: Expand D to 4 append-after-e perts: e+0, e-0, e*1, e**1 => 6 D-D pairs.

(b) Amplification gradient (E-E > D-E > D-D) may be trivial: E perts inject more variance,

so pairs with more answer-shift naturally correlate more. FIX: regress out answer-shift.

(c) Finding 3 (cross-position) rated SOLID.

(d) Finding 4 (trivial inflation): 10-12% is "mostly robust," not "falsified."

54. **StableLM-2-1.6B LATE-TWIN — EDIT LOCALITY ON BOTH READOUTS (2026-09-19).**

3rd architecture, 828 fwd passes, 237s. Sanity: rho=1.0000 vs kill-data.

**Full-logit:** D-D=+0.579, D-E=+0.596, E-E=+0.713. D-D - D-E = **-0.017**.

Bootstrap CI [-0.170, +0.129] (spans zero). EDIT LOCALITY EVEN ON FULL-LOGIT.

**11-bin:** D-D=+0.414, D-E=+0.458, E-E=+0.650. D-D - D-E = **-0.044**.

Bootstrap CI [-0.201, +0.122] (spans zero).

StableLM doesn't encode +/- operator distinction in formatting geometry.

"Meaning matters on FL" is MODEL-SPECIFIC (Qwen3, SmolLM2), not universal.

**Edit locality on 11-bin: NOW 3/3 MODELS.**

| Model | FL D-D-D-E | FL CI | 11b D-D-D-E | 11b CI |

|---|---|---|---|---|

| Qwen3 | +0.234 | [+0.082,+0.382]* | -0.053 | pending |

| SmolLM2 | +0.236 | [+0.106,+0.357]* | +0.015 | [-0.171,+0.200] |

| StableLM | -0.017 | [-0.170,+0.129] | -0.044 | [-0.201,+0.122] |

* = CI excludes zero (meaning matters on FL for these two only)

E-E amplification strongest in StableLM: e+2~e+3 = 0.922 (FL), 0.785 (11-bin).

**Next:** Expanded-D experiment (e*1, e**1, e*2, e**2 added) for 6 D-D pairs.

Addresses the single strongest attack: 1-pair D-D estimate had massive variance.

55. **FABLE R26 ADVERSARIAL REVIEW — LEVEL-OF-ANALYSIS DEMOLITION (2026-09-18).**

Reviewed 6-model balanced kill cross-analysis. **Independently verified all claims.**

**F1: Two-cluster structure DEMOLISHED.** The "two clusters" were a group-ordering artifact. Qwen3 has D>A mean distance; all 4 non-Qwen3 models have D<A. This single bit reproduces the partition. Group-mean-only null gives HIGHER rho than actual data for non-Qwen pairs (S1.7-S360: null +0.800 > actual +0.739). Within-group ranks (group ordering removed): SmolLM2 within-family collapses +0.739 -> +0.014. SmolLM2-StableLM: +0.642 -> +0.129. StLM-Phi: +0.457 -> -0.029. BUT Qwen3-Phi RISES: +0.253 -> +0.614. Qwen3 within-family SURVIVES: +0.943. The "Qwen3 outlier" was group ordering disagreement, not perturbation-level.

**F3: Cell-level vs perturbation-level DISSOCIATION.** Independently verified: Qwen3 within-family: pert rho = +0.937, cell rho = **+0.015 (p=0.90)**. Models agree on WHICH PERTURBATION TYPES are damaging but NOT which CELLS are vulnerable. Split-half cell reliability 0.76-0.98 (not noise — real disagreement). Cell-level cross-model rho exists WITHIN SmolLM2 (+0.496), but NOT within Qwen3. S1.7-Phi: pert +0.543, cell **-0.576** (ANTI-correlated at cell level!).

**F2: H1 weakened.** rho=-0.771, p=0.072, n=6. Without Phi (p_digit=0.0004): p=0.19. eta2 driven by per-operator accuracy dispersion, not mean accuracy.

**F4: Qwen3 tokenizer merge.** c_newline_before merges `\n\n` into one token in Qwen3 tokenizer. This is Qwen3-0.6B's single largest perturbation. Without it, Qwen3's C>A ordering drops to match other models. Does not change cluster rhos.

**RETRACTIONS (R26):**

- ~~Two-cluster structure~~ -> GROUP ORDERING ARTIFACT (one bit: D>A vs D<A)
- ~~SmolLM2 within-family pert rho +0.739~~ -> Drops to +0.014 within-group
- ~~Non-Qwen3 cluster~~ -> COLLAPSES within-group (all pairs near zero)
- ~~Qwen3 as outlier~~ -> Only in group ordering; within-group Qwen3-Phi = +0.61
- ~~"Cross-family = zero" (admissible, pert-level)~~ -> Level artifact; cell rho was already near-zero WITHIN Qwen3 family
- H1 monotonicity -> NOT ESTABLISHED (p=0.19 without Phi)

**SURVIVING (R26-verified):**

- Within-model gap (AA - AD) real for all 6 models
- Qwen3 within-family within-group pert rho = +0.943 (genuine fine-grained)
- Cell profiles reliable (split-half 0.76-0.98)
- Level-of-analysis dissociation itself (pert vs cell rho diverge)

- Qwen3 D>A group ordering (genuine, possibly tokenizer-driven)

**NEW FINDING: LEVEL-OF-ANALYSIS DISSOCIATION.**

Pert-level rho measures "which perturbation types are more damaging overall."

Cell-level rho measures "which arithmetic problems are more vulnerable."

These are INDEPENDENT. Two Qwen3 models agree perfectly on perturbation type

ordering (+0.937) but zero on cell vulnerability (+0.015). This means:

(a) Post-training that targets perturbation types would transfer within-family

(b) Post-training that targets specific problem vulnerabilities would NOT

(c) The "transfer gap" depends entirely on WHAT is transferred (type vs item)

**R26 RECOMMENDATION:** Re-run all 6 models with current runner (per_cell for

all), pre-register within-group analysis. Add 7th model from 4th family >80%

accuracy. Cell-level analysis is the correct level for alignment transfer claims.

56. **DISTANCE MATRIX DECOMPOSITION — FAMILY-SPECIFIC VARIANCE STRUCTURE (zero-cost, 2026-09-18).**

Decomposed each model's 69x24 distance matrix into: Op×Group block means, cell-beyond-

operator, pert-beyond-group, and cell×pert residual. Variance explained:

| Model | OpGrp | CellBeyOp | PertBeyGrp | Residual |

|---|---|---|---|---|

| Q1.7 | 14.6% | 10.4% | **48.2%** | 26.8% |

| Q0.6 | 10.5% | 4.1% | **67.1%** | 18.2% |

| S1.7 | **63.1%** | 14.6% | 2.2% | 20.1% |

| S360 | **67.9%** | 7.7% | 4.8% | 19.5% |

| Phi | **50.2%** | 7.5% | 24.2% | 18.1% |

| StLM | **47.6%** | 18.0% | 12.0% | 22.4% |

**KEY FINDING: The distance matrix has family-specific variance structure.**

- Qwen3: dominated by PERT-BEYOND-GROUP (48-67%). "Which specific perturbation is severe."
- SmolLM2: dominated by OP×GROUP (63-68%). "Which operator×group combos are hard."
- Phi/StableLM: mixed (~50% OpGrp, 12-24% PertBeyGrp).

Cross-model pert-beyond-group (the clean level):

- Qwen3 within: +0.893 (genuine fine-grained). SmolLM2 within: +0.157 (NS!!!).
- Qwen3-Phi: +0.534 (p=0.007). Qwen3-StLM: +0.483. GENUINE cross-family.

Cell-beyond-operator: ALL near zero (Qwen3 within: +0.003). Q1.7-Phi: +0.412 (exception).

Residual (cell×pert): ALL tiny (max +0.263). Model-specific fingerprint.

**IMPLICATION: "Perturbation profile transfer" measures DIFFERENT THINGS per family.**

For Qwen3: shared within-group perturbation ordering (genuine structure).

For SmolLM2: shared group ordering + Op×Group (artifact, collapses within-group).

The high pert rho within SmolLM2 (+0.739) was OpGroup structure, not pert specificity.

SmolLM2 within-family pert-beyond-group = +0.157 (NS) — NO genuine pert agreement.

**TRANSFER DEPENDS ON GRANULARITY:**

- Pert-type level: transfers within Qwen3 (+0.89), Qwen3->Phi (+0.53). NOT SmolLM2.
- Cell level: transfers NOWHERE (all near zero beyond operator).
- Operator level: trivially shared (dominant structure in non-Qwen3 models).
- Residual: unique to each model (max +0.26).

57. **EXPANDED-D LATE-TWIN — SmolLM2: EDIT LOCALITY CONFIRMED WITH 6 D-D PAIRS (2026-09-19).**

Addresses adversarial attack #1 (entry 53a): D-group had only 1 D-D pair.
Added 4 new perts: e*1 (D), e**1 (D), e*2 (E), e**2 (E). Now 4 D + 6 E = 10 perts.
6 D-D pairs, 24 D-E pairs, 15 E-E pairs. 552 new fwd passes (reused 6 existing perts).
**Full-logit:** D-D=+0.449, D-E=+0.269, E-E=+0.209. D-D - D-E = **+0.180**.
Bootstrap CI [+0.074, +0.285] => **MEANING MATTERS** (CI excludes zero).
**11-bin:** D-D=+0.310, D-E=+0.225, E-E=+0.201. D-D - D-E = **+0.085**.
Bootstrap CI **[-0.017, +0.189]** => **MEANING NOT DETECTED** (CI spans zero).
INTERPRETATION: With 6x more D-D pairs, the finding HOLDS. Edit locality on 11-bin is
not an artifact of 1-pair D-D variance. D-D means dropped (from 0.704 to 0.449 FL, 0.365
to 0.310 11-bin) because e*1/e**1 correlate less with e+0/e-0 than they do with each other
(e*1~e**1 = 0.662 FL, 0.521 11-bin vs e+0~e*1 = 0.250 FL, 0.283 11-bin).
NOTABLE: e*1/e**1 correlate HIGH with e*2/e**2 (same operator family, different meaning):
e*1~e*2 = 0.663 FL, 0.262 11b. e**1~e**2 = 0.659 FL, 0.510 11b.
OPERATOR FAMILY > MEANING. Pairs sharing an operator (regardless of D/E) correlate more
than pairs sharing meaning-preservation status but different operators.
StableLM expanded-D RUNNING.

**Next:** StableLM expanded-D (reuses existing JSON), then Qwen3 (all 10 perts from scratch).

58. **SVD DECOMPOSITION — QWEN3 CELL ANTI-TRANSFER (zero-cost, 2026-09-18).**
Rank-1 SVD of centered 69x24 distance matrices.
V1 (pert severity): Q1.7-Q0.6 = +0.914 (shared). U1 (cell fragility): Q1.7-Q0.6 =
**-0.421** (p=0.0003, ANTI-correlated!). Since V1 same-sign and U1 opposite, the
rank-1 interaction is anti-correlated: cells fragile for Q1.7 are robust for Q0.6.
**Mechanism:** Different operator vulnerability rankings across Qwen3 scales.
Q1.7 top fragile: % and // (7 of top 10). Q0.6 top fragile: - (8 of top 10).
Cell-beyond-operator still +0.003 — even within same operator, cell orderings differ.
Rank-1 accounts for 68-83% of variance; rank-2 reaches 84-94% (low-rank matrix).
Multiplicative model (d = f(cell)*g(pert)) better than additive for 5/6 models.
Q1.7-Phi cell-beyond-op agreement (+0.412) driven by % operator (rho=+0.675, p=0.006).
"Universal" cell fragility is SmolLM2/StableLM-specific (+0.63), not Qwen3/Phi (0).
R27 adversarial review RUNNING.

59. **MULTIPLICATIVE RESIDUAL STRUCTURE — GAP SURVIVES AND GROWS (zero-cost, 2026-09-18).**
After log-additive residualization (removing cell_fragility × pert_severity):

| Model | Gap_raw | Gap_residual | AA_res | AD_res | DD_res |
|---|---|---|---|---|---|
| Q1.7 | +0.500 | **+0.532** | +0.255 | -0.277 | +0.140 |
| Q0.6 | +0.271 | **+0.475** | +0.277 | -0.198 | +0.028 |
| S1.7 | +0.275 | **+0.647** | +0.449 | -0.198 | +0.016 |
| S360 | +0.244 | **+0.710** | +0.445 | -0.265 | +0.092 |
| Phi | +0.034 | +0.037 | -0.019 | -0.056 | +0.038 |
| StLM | +0.215 | **+0.646** | +0.488 | -0.158 | -0.026 |

AD residuals are ANTI-correlated in 5/6 models — cells unusually sensitive to
inert perturbations (beyond multiplicative prediction) are unusually ROBUST to
semantic perturbations. The gap is a property of the RESIDUAL after multiplicative
structure, not of the main effects.

**FULL 2-BLOCK STRUCTURE (universal across 5 models):**

- {A,B} block: internal rho +0.25 to +0.54 (after-position inerts cohere)
- {C} block: internal rho +0.07 to +0.38 (before-position perts cohere)
- {A,B} vs {C}: NEGATIVE rho -0.17 to -0.40 (position-dependent anti-transfer)
- {A,B} vs {D}: NEGATIVE rho -0.16 to -0.31 (inert vs semantic anti-transfer)
- {C} vs {D}: near zero (independent)

**MECHANISM:** Cells differ in WHAT PART OF THE CONTEXT they depend on. After-position perturbations test late-context dependence. Before-position test early-context. Cells that depend on late context are sensitive to A/B but not C, and vice versa. D (semantic rewrites) anti-correlates with late-context-dependent cells. This is a position × cell interaction that EXPLAINS the gap structure.

60. **StableLM EXPANDED-D — EDIT LOCALITY CONFIRMED, FL MARGINAL (2026-09-19).**
552 new fwd passes (4 new perts, 6 reused), 166s compute.
**Full-logit:** D-D=+0.706, D-E=+0.611, E-E=+0.617. D-D - D-E = +0.095.
CI [+0.009, +0.194] => FL meaning barely significant (lower bound at +0.009).
REVERSAL from original late-twin: original had CI [-0.170, +0.129] (no FL effect).
**11-bin:** D-D=+0.540, D-E=+0.478, E-E=+0.539. D-D - D-E = +0.062.
CI [-0.010, +0.140] => MEANING NOT DETECTED.

61. **QWEN3 EXPANDED-D — FL MEANING VANISHES, 11-BIN REVERSES (2026-09-19).**
1380 fwd passes (all 10 perts from scratch, no existing JSON), 522s compute.
**Full-logit:** D-D=+0.389, D-E=+0.341, E-E=+0.321. D-D - D-E = +0.048.
CI **[-0.050, +0.148]** => MEANING NOT DETECTED (was [+0.082, +0.382] with 2 D perts!).
**11-bin:** D-D=+0.451, D-E=+0.562, E-E=+0.669. D-D - D-E = **-0.111**.
CI **[-0.186, -0.033]** => **REVERSE MEANING** (CI excludes zero, NEGATIVE!).
D perts correlate MORE with E perts than with each other on 11-bin.
Driven by: e-0~e**1 = 0.062 (outlier low D-D pair) + high D-E on 11-bin (e+0~e+3 = 0.829).
DEMOLISHES "meaning matters on FL" for Qwen3: adding e*1/e**1 to D breaks the additive-family coherence that drove the original D-D > D-E.

**3-MODEL EXPANDED-D TABLE (the definitive result):**

| | Qwen3 FL | Qwen3 11b | SmolLM2 FL | SmolLM2 11b | StableLM FL | StableLM 11b |
|---|---|---|---|---|---|---|
| D-D | +0.389 | +0.451 | +0.449 | +0.310 | +0.706 | +0.540 |
| D-E | +0.341 | +0.562 | +0.269 | +0.225 | +0.611 | +0.478 |
| E-E | +0.321 | +0.669 | +0.209 | +0.201 | +0.617 | +0.539 |
| Gap | +0.048 | **-0.111** | +0.180 | +0.085 | +0.095 | +0.062 |
| CI | [-0.050,+0.148] | [-0.186,-0.033]* | [+0.074,+0.285]* | [-0.017,+0.189] | [+0.009,+0.194]* | [-0.010,+0.140] |

* = CI excludes zero.

**11-bin: 0/3 show positive meaning effect. 1/3 (Qwen3) shows REVERSE.**
**FL: 1/3 clear (SmolLM2), 1/3 marginal (StableLM), 1/3 not detected (Qwen3).**

62. **OPERATOR FAMILY DECOMPOSITION — MEANING DEAD WITHIN FAMILY (zero-cost, 2026-09-19).**
Decomposed all 45 expanded-D pairs by operator family (+/- = additive, * = mult, ** = exp).

| Metric | Q FL | Q 11b | S2 FL | S2 11b | StLM FL | StLM 11b |
|---|---|---|---|---|---|---|
| Family effect (same-cross) | +0.157 | +0.119 | **+0.422** | +0.216 | +0.022 | +0.026 |

| Meaning (same-family) | +0.221 | **+0.002** | +0.197 | **+0.008** | **-0.065** | **-0.090** |

| Meaning (cross-family) | +0.063 | -0.119 | +0.299 | +0.168 | +0.145 | +0.105 |

**UNIVERSAL: Within same operator family, meaning on 11-bin = +0.002, +0.008, -0.090.**

All three models agree: ZERO within-family meaning effect on answer distribution.

The aggregated D-D > D-E on FL is operator-family clustering (SmolLM2) or noise (StableLM).

Same-family D-E can EXCEED same-family D-D: e+0~e+1 > e+0~e-0 in SmolLM2 FL (0.810 > 0.704).

Cross-family D-E (low in SmolLM2: 0.100) is what drives the overall D-D > D-E gap.

**IMPLICATION:** The distance profile is organized by: (1) position of edit, (2) operator character at the edit site, (3) NOT meaning preservation. "Meaning matters on FL" was operator-family coherence. "Meaning dead on 11-bin" was already correct; now confirmed at the finest grain (within-family) across all 3 architectures.

62b. **SmolLM2-360M EXPANDED-D — BOTH SURFACES REVERSED (2026-09-20).**

4th model. 1380 fwd passes, 118s. FL: D-D-DE=-0.031 CI[-0.076,+0.009]. 11b: -0.035 CI[-0.097,+0.024]. BOTH REVERSED. D-E > D-D on both surfaces. e+0~e+1=+0.926 FL (same-family D-E) vs e+0~e**1=+0.632 (cross-family D-D). Family confound confirmed.

62c. **ADVERSARIAL REVIEW OF EXPANDED-D — FAMILY CONFOUND (Fable, 2026-09-20).**

Ratings: (1) meaning-dead-on-11b QUALIFIED (failure-to-reject ≠ evidence-for-null);

(2) FL=family-clustering SOLID; (3) family>meaning QUALIFIED (true by construction);

(4) expanded-D-addresses-1-pair FRAGILE (introduced worse confound than it solved).

**CRITICAL:** D={+0,-0,*1,**1} spans 3 families. D-D is cross-family, D-E includes same-family. Fix: same-family D expansion (additive-only). ~276 fwd passes per model.

62d. **ZERO-COST 2×2 SIGN × MEANING — CROSS-SIGN MEANING EFFECT (2026-09-20).**

Existing expanded-D data, 2×2 decomposition (sign-match × meaning-match).

Cross-sign meaning effect (D-D minus D-E, holding sign at cross), 11-bin:

| Model | D-D cross-sign | D-E cross-sign | Δ (meaning) |

|---|---|---|---|

| Qwen3-1.7B | +0.591 | +0.591 | 0.000 |

| SmolLM2-1.7B | +0.365 | +0.307 | +0.058 |

| StableLM-2-1.6B | +0.414 | +0.318 | +0.096 |

| SmolLM2-360M | +0.657 | +0.573 | +0.084 |

11-bin: 3/4 positive (Qwen3 = 0). Sign effect dominates across ALL models.

BUT: n=1 D-D pair (+0~-0) — no CI. Suggestive only.

**Same-family +(0)/-(0) design reviewed by Fable: FATAL (sign+form confound).**

Fix: isomorphic design D={+0,-0,+(0),-(0)}, E={+1,-1,+(1),-(1)}.

62e. **ISOMORPHIC SAME-FAMILY — SmolLM2-1.7B: MEANING ALIVE (2026-09-20).**

Design: D={+0,-0,+(0),-(0)}, E={+1,-1,+(1),-(1)}. Isomorphic sign×form.

552 fwd passes (124s). 4 new perts, 4 reused from expanded-D.

**Full-logit:** D-D=+0.782, D-E=+0.676, E-E=+0.627. Gap=+0.106.

Unstructured permutation p=0.086 (not sig). Sign-structured p=0.028 (SIG).

Cell-bootstrap CI: [+0.054, +0.165] EXCLUDES ZERO.

Stratified: same-sign meaning +0.099, cross-sign +0.158, same-form +0.036, cross-form +0.161.

**11-bin:** D-D=+0.489, D-E=+0.257, E-E=+0.322. Gap=+0.233.

Unstructured permutation p=0.043 (SIG). Sign-structured p=0.028 (SIG).

Cell-bootstrap CI: [+0.120, +0.349] EXCLUDES ZERO.

Stratified: same-sign meaning +0.448, cross-sign +0.157, same-form +0.065, cross-form +0.334.

**MEANING IS SIGNIFICANT ON BOTH SURFACES.** Within the additive family,
answer-preserving perts correlate more than answer-changing perts, even after
controlling sign and form. The expanded-D negative result was caused by cross-family
composition of D-D, not by absence of meaning. Operator-family heterogeneity masked
a real meaning effect.

Remaining 3 models completed:

62f. **ISOMORPHIC SAME-FAMILY — 4-MODEL COMPLETE: MEANING IS MODEL-DEPENDENT (2026-09-20).**

| Model | FL gap | FL CI | 11b gap | 11b CI |
|---|---|---|---|---|
| SmolLM2-1.7B | +0.106 | [+0.054, +0.165]* | +0.233 | [+0.120, +0.349]* |
| Qwen3-1.7B | +0.169 | [+0.059, +0.273]* | +0.046 | [-0.035, +0.139] |
| StableLM-2-1.6B | +0.017 | [-0.040, +0.076] | +0.010 | [-0.053, +0.078] |
| SmolLM2-360M | -0.004 | [-0.034, +0.030] | -0.011 | [-0.060, +0.033] |

FL: 2/4 sig. 11-bin: 1/4 sig. Meaning is MODEL-DEPENDENT, not universal.
SmolLM2-1.7B is the outlier: both surfaces significant.
Factor ordering: position >> operator family >> meaning (model-specific).

62g. **MULTIPLE TESTING CHECK — PERMUTATION UNDERPOWERED (2026-09-20).**
8 tests (4 models × 2 surfaces). Bonferroni threshold = 0.006.
C(8,4)=70 permutations → min possible p = 1/70 = 0.014.
MATHEMATICALLY IMPOSSIBLE for permutation test to survive Bonferroni for 8+ tests.
Resolution artifact, not evidence against the effect.
Bootstrap CIs (2000 resamples, continuous resolution): 3/8 exclude zero
(SmolLM2 FL [+0.054,+0.165], SmolLM2 11b [+0.120,+0.349], Qwen3 FL [+0.059,+0.273]).
CIs address cell-level stability of the gap, not the pert-label permutation question.

62h. **ANSWER IDENTITY CONFOUND — ISOMORPHIC MEANING EFFECT RETRACTED (2026-09-20).**
Adversarial review (Fable R28) identified that DD-DE is NOT the isomorphic comparison.
DD-EE is (matched sign×form composition). DD-DE has answer identity PERFECTLY COLLINEAR
with the D/E label: all D perts produce answer=x, all E perts produce answer=x±1.

Independent verification via answer identity confound test:
Cleanest test: compare D-D against E-E-same-sign (BOTH have matching answers within pair).
If meaning matters beyond answer identity, D-D > E-E-same-sign.

**Result: D-D <= E-E-same-sign in ALL 8 model×surface tests.**

| Model | Surface | D-D | EE-same-sign | Diff |
|---|---|---|---|---|
| SmolLM2-1.7B | FL | +0.782 | +0.770 | +0.012 (null) |
| SmolLM2-1.7B | 11-bin | +0.489 | +0.538 | -0.048 (REVERSE) |
| Qwen3-1.7B | FL | +0.563 | +0.588 | -0.025 (null) |
| Qwen3-1.7B | 11-bin | +0.562 | +0.765 | -0.204 (REVERSE) |
| StableLM | FL | +0.722 | +0.853 | -0.131 (REVERSE) |
| StableLM | 11-bin | +0.596 | +0.769 | -0.173 (REVERSE) |
| SmolLM2-360M | FL | +0.815 | +0.933 | -0.118 (REVERSE) |
| SmolLM2-360M | 11-bin | +0.717 | +0.895 | -0.178 (REVERSE) |

Variance decomposition: answer identity $R^2$ > meaning $R^2$ for SmolLM2-1.7B (the model
that "showed" meaning). For 6/8 tests: both $R^2 < 0.06$ (dominant factor is sign matching).

**RETRACTED:** "Meaning is model-dependent" → meaning has NO independent signal.
**RETRACTED:** "SmolLM2-1.7B shows genuine meaning effect" → answer identity confound.
**RETRACTED:** "Capacity threshold within SmolLM2 family" → no effect to threshold.

**Deeper insight:** In arithmetic, meaning preservation ≡ answer identity. They CANNOT
be separated. The isomorphic design controlled sign and form but NOT answer identity.
Dominant correlation factor is sign matching (same-sign vs cross-sign gap ~0.18),
not meaning (gap ~0.01 when controlling for answer identity).

**STILL STANDING:** Original gap (AA-AD) is real — both A and D produce the same answer,
so the original experiment IS controlled for answer identity. The gap measures
SURFACE FORM sensitivity, not meaning non-transfer.

Review also found: (1) DD-EE comparison (the correct isomorphic one) shows nothing
significant (SmolLM2 FL p=0.071, 11b p=0.157), (2) manipulation check fails —
E perts barely move the answer more than D perts (median E/D distance ratio 1.17-1.20),
(3) sign-structured permutation null is biased (every relabeling keeps asymmetric sign
proportions in DD vs DE).

62i. **CORRELATION STRUCTURE REGRESSION — SIGN IS THE DOMINANT FACTOR (2026-09-20).**
OLS: rho ~ sign_match + form_match + answer_match across 224 observations
(4 models x 2 surfaces x 28 pairs).

R-squared = 0.236.
sign_match: +0.191 (incremental R2 = 0.183) — DOMINANT
answer_match: +0.101 (incremental R2 = 0.042)
form_match: +0.038 (incremental R2 = 0.007)
same_group: +0.035 (incremental R2 = 0.003) — meaning adds NOTHING

Per-model sign gap: 0.11-0.30 in 7/8 conditions. Qwen3 11b anomaly (~0).
Per-model form gap: -0.054 to +0.070 — INCONSISTENT direction.
Per-model answer gap: 0.046-0.253 — always positive, largest on SmolLM2 11b.

D vs E distance CV: D perts NOT more uniform than E perts. In SmolLM2,
D has HIGHER CV. The "D uniformity" alternative doesn't explain DD.

**Hierarchy: position >> sign >> answer >> form >> meaning (dead).**
76% of variance unexplained (model-specific + cell-specific effects).

**Next:** Meaning closed for arithmetic. Sign dominance is the actionable finding.
Now: what's the highest-information-gain question that's field-changing?
(a) Can sign predict few-shot transfer? (connect to practical scenarios)
(b) What cell-level features predict sensitivity? (explain the 76%)
(c) Non-arithmetic domain (meaning ≠ answer identity)
(d) Is sign dominance robust to more perturbation diversity?

63. **FABLE R27 ADVERSARIAL REVIEW — GAP IS D-COLUMN RELIABILITY ARTIFACT (2026-09-18).**
R27 reviewed entries 55-59. Independently verified all claims below.

**DEVASTATING FINDING: AB = AA.** Group A (inert suffix) is NOT privileged:
| Model | AA | BB | AB | AA-AB |
|---|---|---|---|---|

| Q1.7 | 0.762 | 0.763 | 0.765 | -0.003 |

| Q0.6 | 0.696 | 0.695 | 0.730 | -0.034 |

| S1.7 | 0.944 | 0.919 | 0.929 | +0.015 |

| S360 | 0.780 | 0.752 | 0.778 | +0.002 |

| Phi | 0.851 | 0.739 | 0.813 | +0.038 |

| StLM | 0.939 | 0.958 | 0.950 | -0.011 |

AA-AB is indistinguishable from zero in 5/6 models. The "gap" compares A vs D,

but B (novel suffix) is identical to A. The A/D distinction is not inert/semantic.

**DD << AA — D-column unreliability drives the gap:**

| Model | AA | DD | DD/AA ratio |

|---|---|---|---|

| Q1.7 | 0.762 | 0.134 | 0.18 |

| Q0.6 | 0.696 | 0.392 | 0.56 |

| S1.7 | 0.944 | 0.531 | 0.56 |

| S360 | 0.780 | 0.412 | 0.53 |

| Phi | 0.851 | 0.824 | 0.97 |

| StLM | 0.939 | 0.576 | 0.61 |

Q1.7 D reliability is 0.134 — barely above zero. Per-column D reliabilities

range from -0.089 to 0.525 (Q1.7). D perts add idiosyncratic noise.

**Disattenuated A-D = AD/√(AA·DD) near 1 for 4/6 models:**

| Model | Disattenuated AD | Interpretation |

|---|---|---|

| Q1.7 | 0.819 | Genuine departure |

| Q0.6 | 0.815 | Genuine departure |

| S1.7 | 0.945 | ≈1 (noise only) |

| S360 | 0.945 | ≈1 (noise only) |

| Phi | 0.976 | ≈1 (noise only) |

| StLM | 0.984 | ≈1 (noise only) |

For SmolLM2, Phi, StableLM: D perts don't shift WHICH cells are vulnerable —

they just add per-pert noise. Only Qwen3 shows genuine cell-ranking shift under D.

**Phi permutation test FAILS (p=0.31):**

| Model | Gap | Perm p |

|---|---|---|

| Q1.7 | 0.500 | <0.001 |

| Q0.6 | 0.271 | 0.016 |

| S1.7 | 0.275 | <0.001 |

| S360 | 0.244 | 0.012 |

| Phi | 0.034 | **0.312** |

| StLM | 0.215 | 0.026 |

"Gap significant for all 6 models" is FALSE. Phi fails. Q0.6/S360/StLM marginal.

**RETRACTIONS (R27):**

- ~~"Gap is significant for all 6 models"~~ → Phi fails permutation (p=0.31)

- ~~"A-D gap measures inert vs semantic"~~ → AB=AA; A not special; gap = D unreliability

- ~~"D perturbations shift cell vulnerability ranking"~~ → Disattenuated AD ≈ 1 for 4/6

- ~~"Header sensitivity is incidental"~~ → Everything measured IS header sensitivity
- ~~Multiplicative residual gap "survives and grows"~~ → Grows because D noise amplifies in log space

**WHAT THE GAP ACTUALLY IS:** d[cell,pert] = cosine(logits_minimal, logits_verbose)
where surfaces differ only by `# Python code\n` header. The "gap" measures: D perts
add more idiosyncratic noise to the header-sensitivity profile than A/B perts. Real
but not what was claimed.

**SURVIVING (R27-verified):**
1. Qwen3 within-family pert ordering (+0.893) — robust under all analysis variants
2. Reliable-within/absent-across cell dissociation (split-half 0.85-0.95, cross≈0)
3. Fragile ~0.5 cross-family pert cluster (Qwen3↔Phi/StLM, dies under exclusions)
4. Qwen3-only genuine departure (disattenuated AD = 0.82, CI excludes 1)

**R27 RECOMMENDED EXPERIMENT:** 2×2 on Qwen3-0.6B (~4 min CPU):
{semantic op, inert} × {adjacent to expression, own line}. If D variants agree at AA
level while different ops don't → gap has content (structured semantic interaction).
If variants disagree → D profiles are token noise → gap dead as semantic measure.

64. **SMOLLM2-1.7B-INSTRUCT BALANCED KILL COMPLETE (2026-09-18).**
3rd attempt (PowerShell, after two Bash exit-127 failures). 968s CPU.
- Accuracy: 93.4%, P(digit) median: 0.9252 — ADMISSIBLE
- Gap: 0.307 [0.231, 0.397], Z=4.1
- eta2_op: 0.500 (base: 0.687 — IT reduced operator dominance)
- AA=0.888, DD=0.458, AB=0.795, AD=0.581
- Residual gap: 0.452

**IT comparison (SmolLM2-1.7B Base vs Instruct):**

| Metric | Base | Instruct |
|---|---|---|
| Accuracy | 87.6% | 93.4% |
| Gap | 0.275 | 0.307 |
| AA | 0.944 | 0.888 |
| DD | 0.531 | 0.458 |
| eta2_op | 0.687 | 0.500 |
| Disattenuated AD | 0.945 | 0.912 |

**Cross-model (base↔instruct):**
- Cell mean d: rho = +0.763 (strong)
- Pert mean d: rho = +0.873 (very strong)
- Pert-beyond-group: rho = +0.624 (p=0.001) — STRONGER than S1.7↔S360 (+0.157 NS!)
- Cell-beyond-operator: rho = +0.572 (p<0.001)

**KEY FINDING:** IT preserves most structure. Base↔Instruct pert-beyond-group (+0.624)
is MUCH stronger than within-family scale pair S1.7↔S360 (+0.157 NS). Instruction
tuning shares more perturbation ordering with its base than a same-family smaller model
does. This is the first clean within-family comparison where one pair transfers and the
other doesn't — and it's tuning > scale.

65. **R27 2×2 D-RELIABILITY DIAGNOSTIC — D IS STRUCTURED, ADJACENCY IS THE DRIVER (Qwen3-0.6B, 2026-09-20).**
3312 forward passes, 364s CPU. 24 perts: A (original), D (original), V (lexical variants

of D), O (own-line versions of D).

**KEY TEST: Within-op D↔V rho vs cross-op rho:**

| Operation | D↔V rho | Note |
|---|---|---|
| temp_var (_t vs tmp) | **-0.346** | ANTI-correlated! Token noise. |
| parens ((e) vs ( e )) | +0.865 | Structured |
| int_cast | +0.889 | Structured |
| add_zero (+0 vs +(0)) | +0.876 | Structured |
| zero_plus (0+ vs (0)+) | +0.650 | Structured |
| cond_true (True vs (True)) | +0.858 | Structured |

Within-op mean: **+0.632**. Cross-op mean: **+0.366**. Difference: **+0.266**.

→ D unreliability is STRUCTURED: 5/6 operations reliably measure different cell properties.

temp_var is the exception — variable name (_t vs tmp) flips the cell ranking.

**OWN-LINE TEST:**

| Group | Within rho |
|---|---|
| A-A | +0.696 |
| O-O | **+0.660** |
| D-D | +0.392 |
| V-V | +0.299 |

Own-line semantic ops (O) behave like inert perts (A), NOT like adjacent D.

A-O cross = +0.552. When same operation is detached from expression, it becomes reliable.

→ **ADJACENCY to the expression** is what makes D unreliable. Token-level interaction

between modification and expression tokens creates cell-specific, position-dependent noise.

**IMPLICATION FOR R27:** R27 correctly identified D-column unreliability but overclaimed

"gap is dead." For Qwen3, the gap has genuine structured content — different semantic

operations DO probe different cell vulnerability patterns (within-op rho 0.65-0.89).

The noise is from (1) adjacency-induced token interactions and (2) one specific operation

(temp_var) where variable name matters. The disattenuated AD = 0.82 captures real content.

**IMPLICATION FOR ALIGNMENT:** WHERE you modify code matters more than WHAT modification

you make. Adjacent modifications create unique, cell-specific interactions with the original

expression. Detached modifications (on their own line) are treated uniformly — like inert

perturbations. Alignment testing should distinguish between modifications that touch vs.

are detached from the aligned behavior.

66. **R27 2×2 D-RELIABILITY DIAGNOSTIC — ADJACENCY REPLICATES ON SMOLLM2-360M (2026-09-20).**

3312 forward passes, 237s CPU. 69 balanced cells × 24 perts × 2 surfaces. **Accuracy: 55.9%**

(below 80% admissibility threshold — caveat applies, but adjacency finding is about

RELATIVE within-group reliabilities, not absolute accuracy).

**Cross-model comparison (Qwen3-0.6B vs SmolLM2-360M):**

| Metric | Qwen3-0.6B | SmolLM2-360M |
|---|---|---|
| A-A within | +0.696 | **+0.780** |
| O-O within | **+0.660** | +0.609 |
| D-D within | +0.392 | +0.412 |

| V-V within | +0.299 | +0.550 |

| A-O cross | +0.552 | +0.409 |

| A-D cross | +0.425 | +0.536 |

| Within-op D↔V | +0.632 | **+0.912** |

| Cross-op | +0.366 | +0.481 |

**ADJACENCY EFFECT ON RELIABILITY REPLICATES:** O-O >> D-D in both models.

Detached operations are more internally consistent than adjacent ones.

- Qwen3: O-O (0.660) >> D-D (0.392), gap = 0.268

- 360M: O-O (0.609) >> D-D (0.412), gap = 0.197

**NUANCE IN 360M — ADJACENCY ≠ INERTNESS:**

In Qwen3, O-O (0.660) ≈ A-A (0.696) and A-O (0.552) > A-D (0.425): own-line ops

behave like inert perts in both reliability AND pattern.

In 360M, O-O (0.609) is BETWEEN A-A (0.780) and D-D (0.412), closer to midpoint (0.596).

A-O (0.409) < A-D (0.536): own-line ops probe DIFFERENT cell patterns from inert,

despite having HIGHER internal reliability.

→ Adjacency affects RELIABILITY (O-O > D-D: replicates), but NOT necessarily PATTERN

(A-O vs A-D: model-dependent).

**D STRUCTUREDNESS MUCH STRONGER IN 360M:**

| Op | Qwen3 D↔V | 360M D↔V |

|---|---|---|

| temp_var | **-0.346** | **+0.821** |

| parens | +0.865 | +0.977 |

| int_cast | +0.889 | +0.940 |

| add_zero | +0.876 | +0.952 |

| zero_plus | +0.650 | +0.838 |

| cond_true | +0.858 | +0.943 |

| MEAN | +0.632 | **+0.912** |

360M shows ALL 6 operations structured (0.82-0.98). temp_var (variable rename)

flips from anti-correlated in Qwen3 (-0.346) to structured in 360M (+0.821).

Variable name sensitivity is model-specific; operational structure is universal.

**REVISED INTERPRETATION:**

- Adjacency makes perts UNRELIABLE (D-D low) — **universal** (2 models)

- Detachment makes perts MORE reliable (O-O > D-D) — **universal** (2 models)

- Detachment makes perts INERT-LIKE (O ≈ A) — **model-specific** (Qwen3 yes, 360M no)

- D operations are structured (within-op >> cross-op) — **universal** (2 models)

- Variable name sensitivity (temp_var) — **model-specific** (noise in Qwen3, structured in 360M)

67. **FABLE R29 ADVERSARIAL REVIEW — RETRACTION OF RETRACTION + ADJACENCY FRAGILE (2026-09-20).**

R29 recomputed all numbers from raw JSONs. Six entries on board e5a4e16f.

**62h "MEANING IS DEAD" RETRACTION WAS OVERCLAIMED.**

The original D-D vs E-E-same-sign comparison was biased: D-D averaged 6 pairs (4 cross-sign),

E-E-same-sign averaged 2 (all same-sign). Since sign adds +0.19, D-D was penalized.

Correct comparison: DDsame vs EEsame (matched sign AND form, n=2 pairs each side):

| Model | Surface | DDsame | EEsame | Diff | CI |

|---|---|---|---|---|---|

| SmolLM2-1.7B | FL | +0.875 | +0.770 | **+0.105** | **[+0.025, +0.199]** excl 0 |
| SmolLM2-1.7B | 11-bin | +0.768 | +0.538 | **+0.231** | **[+0.116, +0.350]** excl 0 |
| Qwen3-1.7B | FL | +0.597 | +0.588 | +0.009 | [-0.151, +0.175] incl 0 |
| Qwen3-1.7B | 11-bin | +0.633 | +0.765 | **-0.132** | **[-0.261, -0.017]** excl 0 REVERSED |
| StableLM | FL | +0.910 | +0.853 | +0.058 | [+0.001, +0.130] excl 0 |
| StableLM | 11-bin | +0.849 | +0.769 | +0.079 | [-0.001, +0.168] incl 0 |
| SmolLM2-360M | FL | +0.956 | +0.933 | +0.023 | [-0.008, +0.063] incl 0 |
| SmolLM2-360M | 11-bin | +0.941 | +0.895 | +0.046 | [+0.014, +0.082] excl 0 |

Score: 4/8 DDsame > EEsame (CI excl 0), 1/8 reversed (Qwen3 11-bin), 3/8 null.

**CORRECTION:** Meaning has a SMALL, MODEL-DEPENDENT signal, not zero. SmolLM2-1.7B strongest; Qwen3 shows null or reversed. Caveat: n=2 pairs per side; CI covers cell resampling only, not pair resampling. The 11-bin SmolLM2 effect (+0.231) driven by minus_one~minus_paren_one anomaly (0.353 vs all others >0.7) — possible form×sign interaction.

**62i REGRESSION PARAMETRIZATION WAS A CHOICE, NOT A FINDING.**

`meaning_match` was coded as `same_group` — D-D and E-E coded identically. A real `both_D` feature gives +0.007 with answer in the model; +0.112 without. Meaning vs answer identity is NON-IDENTIFIABLE in this design. The "sign >> answer >> meaning" hierarchy below sign is unresolvable from this data.

**ADJACENCY CLAIM DOWNGRADED TO FRAGILE.**

- O-O > D-D REPLICATES (CI [0.07, 0.35])
- "O behaves like A" FAILS on 360M: A-A − O-O CI [0.04, 0.31] excl 0; A-O < A-D
- Design confound: "inside the measured line" vs "adjacency to expression tokens" not separated. R14's f_semicolon (0.872) hints inside-line inerts CAN be reliable.
- R29 recommended experiment: add inside-line inert group I = {`x = e # c`, `x = e;`, `x = e ;`, `x = e `, `x = e\t`, `x = e`}. RUNNING on Qwen3-0.6B.

**DISATTENUATED AD (Claim 6) REFUTED AS D-SPECIFIC (R29).**

On Qwen3-0.6B: disatt A-D=0.815, A-O=0.815, A-V=0.829, D-O=0.846. EVERY non-A class departs from A equally. What's special is A (near-duplicate columns: a_empty~a_newline rho=0.98), not D. The "genuine departure" is A tightness, not D specificity.

**SURVIVING (R29-VERIFIED):**

The single most robust finding: same-locus after-assignment appends are exchangeable (A-A ≈ A-B ≈ B-B, 0.83-0.97 across 8+ models/readouts), while any edit to the assignment line yields a less reliable, partially distinct profile. Everything about WHAT the in-line edits mean has died or is unidentified.

**OTHER R29 CORRECTIONS:**

- Phi p=0.31 is NOT a gap failure — Phi balanced kill is inadmissible (P(digit)=0.0004)
- IT > scale (claim 5): Fisher z=1.86, p=0.063 — NOT significant
- "76% unexplained": half is between model×surface; within-condition $R^2$=0.46
- Hygiene: scripts in scratchpad only, not in experiments/

68. **R29 INSIDE-LINE INERT EXPERIMENT — ADJACENCY-TO-EXPRESSION CONFIRMED (Qwen3-0.6B, 2026-09-20).**

4140 forward passes, 422s CPU, 69 cells x 30 perts x 2 surfaces. Accuracy: 88.8%.
5 groups: A (after-line inert), I (in-line inert), D (in-line semantic), V (D variants), O (own-line semantic).

**DECISIVE 2x2 RESULT:**

| | Same expression | Changed expression |
|---|---|---|
| Same line | **I = 0.708** | D = 0.392 |
| Different line | A = 0.696 | O = 0.660 |

**Line position effect (I vs A): +0.012 (ZERO).** Being on the assignment line does NOT make a perturbation unreliable if it doesn't modify the expression.
**Expression modification effect (I vs D): -0.316 (HUGE).** Modifying the expression creates cell-specific token interactions that destroy reliability.

Cross-group:
- A-I = +0.728: inline inerts and after-line inerts probe SAME cell pattern
- A-D = +0.425: expression modifications probe DIFFERENT pattern
- I-D = +0.394: inline inerts != expression modifications despite same line

Per-pert I reliabilities (5/6 A-like):
i_comment=0.777, i_semicolon=0.799, i_semi_space=0.777, i_trail_tab=0.770, i_extra_space=0.757. Anomaly: i_trail_space=0.367 (trailing spaces before newline).

**MECHANISM:** Token interaction between modification and expression tokens. Non-expression edits (comments, semicolons, whitespace) have ZERO effect on reliability regardless of line position. Expression modifications (operators, wrapping, renaming) create unique cell-specific patterns. Adjacency means expression proximity, not line position.

**DESIGN FLAW FOUND:** i_trail_space and a_whitespace produce IDENTICAL strings (both = `x = e `). The "anomaly" is a duplicate. Corrected (excl both): A-A = +0.826, I-I = +0.878, A-I = +0.847. Conclusion STRENGTHENED: expression modification effect rises from 0.316 to 0.486.

69. **R30 adversarial review of inline-inert claim (2026-09-20).**
Verdict: **PROVISIONAL.** 15 concerns, 4 SERIOUS:

(1) i_trail_space = a_whitespace DUPLICATE (independently confirmed).
(2) "Inert" single-token edit (double space) reproduces D-sized drop → expression modification SUFFICIENT but NOT NECESSARY. Claim must be weakened.
(5) No I pert touches the operand span. Adjacency vs semantics STILL CONFOUNDED. Need in-expression inerts: `x = 1 + 1`, `x = ( 1 + 1 )`.
(10) Selection bias: I group edits are all outside-expression, not randomly sampled.

Also SERIOUS: (4) D-D low = between-op heterogeneity, not unreliability. Reframe.
MODERATE: (7) d_temp_var is two-line, not in-line; D-D excl it = 0.475.
(6) add_zero vs zero_plus (same AST) differs by 0.19 → intra-line position matters.
(8) Pooled rho inflated by operator-block structure; need op-stratified.
(9) n=6 perts, hand-picked; pert-level jackknife swings I-I by 0.17.

RECOMMENDED: (1) in-expression inerts (adjacency vs semantics, the actual test), (2) 10+ perts per group on 2 models with both readouts, (3) whitespace-token census.

**CORRECTIONS TO ENTRY 68:**
- "Expression modification is THE mechanism" → OVERCLAIMED. Trail-space shows inert tokens CAN reproduce the drop. Correct: "expression modification is the PRIMARY driver of D-column heterogeneity; not all token changes are equal."

- "Adjacency-to-expression CONFIRMED" → OVERSTATED. The experiment confirmed that which-LINE has zero effect. It did NOT separate adjacency-to-operands from semantic change because no I pert touches the operand span.
- D-D low should be called "between-op heterogeneity" not "unreliability."
- d_temp_var is misclassified as in-line (it's two-line).

70. **SmolLM2-360M inline-inert replication (2026-09-20).** REPLICATES.
I-I = +0.814, A-A = +0.780, D-D = +0.412. Line position effect: +0.034 (near zero).
Accuracy: 57.6% (below 80% threshold — caveat noted).
Duplicate confirmed: i_trail_space = a_whitespace (bit-identical) in BOTH models.
Corrected (excl duplicates): A-A = +0.746, I-I = +0.789, diff = +0.044.
Cross-model comparison (corrected):

| | Qwen3-0.6B | SmolLM2-360M |
|---|---|---|
| A-A | +0.826 | +0.746 |
| I-I | +0.878 | +0.789 |
| D-D | +0.392 | +0.412 |
| I-I−A-A | +0.052 | +0.044 |
| I-I−D-D | +0.486 | +0.377 |

Model-specific token sensitivity: i_trail_space anomalous in Qwen3 (0.367) but NOT in 360M (0.863). i_extra_space weakest I pert in 360M (0.692) but normal in Qwen3. Different models have different token sensitivities, but the line vs expression pattern is universal.

71. **D-D heterogeneity structure analysis (R29 data, both models).**
Within-group rhos (excl duplicates): A-A=+0.826/+0.746, I-I=+0.878/+0.789, D-D=+0.392/+0.412, V-V=+0.299/+0.550, O-O=+0.660/+0.609 (Qwen3/SmolLM2).

KEY FINDING: D-V same-operation pairs have near-perfect rho (0.865-0.977). Same transformation on different lines = nearly identical cell rankings. Different transformations on same line = rho ~0.4. Heterogeneity is TRANSFORMATION-SPECIFIC, not noise or cell-specific difficulty.

D-D pair structure: d_parens vs d_int_cast is top pair in BOTH models (+0.694/+0.728). d_temp_var is the outlier (lowest pairs: -0.070/+0.328 to +0.433/+0.654). Perturbation magnitude partly explains clustering: d_temp_var is 4-5x larger than d_int_cast/d_parens; meta-corr(rho, mag_diff) = -0.461.

Within-op D-D rho is wildly model-specific: + high in SmolLM2 (+0.657) but moderate in Qwen3 (+0.343); // high in Qwen3 (+0.504) but negative in SmolLM2. Operator-level pattern does NOT replicate.

Predictions for R30 J-group:
- If J-J high + J-I high + J-D low: SEMANTIC CHANGE hypothesis confirmed
- If J-J low + J-D comparable: TOKEN PATTERN hypothesis confirmed
- J perts all have similar magnitudes (small token changes) -> magnitude hypothesis predicts J-J should be moderate-to-high from uniformity alone

72. **R30a in-expression inert results (WRONG PROMPT — code-continuation mode).**
R30a used "print(x)\n" instead of canonical "print(x)\n# Output: " suffix.
Model was in code-continuation mode (predicts next code token, not output).

Accuracy = 0% (expected: model predicts "x" not "2").

R30a results (code-continuation readout):

O-O=+0.852, A-A=+0.806, J-J=+0.619, I-I=+0.538, D-D=+0.283, V-V=+0.064

Despite wrong readout, J-J (+0.619) ≈ I-I (+0.605 excl i_hash_end) >> D-D (+0.283).

Direction already clear: in-expression inerts behave like other inerts.

Cross-R29 comparison: distances 2-3x larger, cross-experiment correlations low

(r=0.13-0.67 for shared perts). i_comment collapsed (R29: +0.88 pairs, R30a: +0.23).

Not comparable to R29 in absolute terms.

ALSO FOUND: a_newline = a_blank duplicate (rho=1.000, identical prompts).

Fixes for R30b: (1) Added "# Output: " suffix, (2) replaced a_blank with a_dead_var.

R30b running.

73. **R30b in-expression inert — CORRECTED after Fable adversarial review (2026-09-20).**

R30b (corrected prompt, a_dead_var replacing a_blank duplicate) on Qwen3-0.6B-Base.

89.4% accuracy (matches R29: 88.8%). 69 cells × 36 perts × 2 surfaces, 1031s wall.

Within-group rhos (POOLED — see op-stratified table below for correct statistics):

| Group | R30b | R29(corr) | R30a(wrong) |
|---|---|---|---|
| A-A | +0.838 | +0.826 | +0.806 |
| I-I | +0.858 | +0.878 | +0.538 |
| **J-J** | **+0.413** | — | +0.619 |
| D-D | +0.392 | +0.392 | +0.283 |
| V-V | +0.299 | +0.299 | +0.064 |
| O-O | +0.660 | +0.660 | +0.852 |

Note: A-A, I-I, D-D, V-V, O-O recomputed on bit-identical data (fp32 CPU deterministic);

deltas reflect only the two swapped perts (a_blank→a_dead_var, i_trail_space→i_hash_end).

**FABLE ADVERSARIAL REVIEW (2026-09-20) — 3 SERIOUS DEFECTS:**

**F1: `//`-comment artifact.** j_space_before_op on 15 `//` cells creates `x = 3 // 4` —

model reads ` // 4` as a C-style comment on the bare surface (argmax "3", p=0.81) while

header surface restores floor division (argmax "0", p=0.84). Mean distance 0.211 on `//`

cells vs 0.015-0.023 on every other operator (10x). j_space_after_op does NOT trigger it

(0.017). These 15 cells dominate pooled rhos for j_space_before_op and j_spaces_both.

**This is a genuine finding** (surface disambiguates language), but it is NOT an adjacency

effect — it is a language-ambiguity artifact that must be excluded from inert-group stats.

**F2: Pooling artifact.** Op-stratified J-J (the correct statistic):

| Statistic | A-A | I-I | J-J | D-D | midpoint(A,D) |
|---|---|---|---|---|---|
| pooled (originally reported) | 0.838 | 0.858 | 0.413 | 0.392 | 0.615 |
| excluding `//` cells (54) | 0.866 | 0.884 | 0.536 | 0.338 | 0.602 |
| op-stratified (+,-,//,%; 15 each) | 0.796 | 0.867 | 0.534 | 0.285 | 0.541 |
| op-strat, clean J (drop j_unary_first) | | | 0.594 | | 0.541 |
| op-strat, clean J (drop unary + spaces_both) | | | 0.563 | | 0.541 |

**Op-stratified J-J = 0.53-0.59 — INTERMEDIATE, not D-like.** At or above the A-D

midpoint (0.541). Per operator: + J-J=0.53, - 0.51, // 0.52, % 0.58. In every block

J sits midway between I and D. "J-J ≈ D-D" was an artifact of pooling across operators combined with the `//`-comment artifact.

**F3: Design flaws in J group.** (a) j_space_before_op ≈ j_spaces_both (pooled rho 0.957, within-// 0.99) — pseudo-replicate, same design error as i_trail_space=a_whitespace in R29. (b) j_unary_first (`x = +3 + 5`) adds UnaryOp(UAdd) AST node — misclassified, belongs in D. 2x magnitude of other non-// J perts (mean 0.040 vs 0.016-0.023).
Clean J group: 4 perts (space_after_op, space_before_op, parens_first, parens_second).

**CORRECTED RESULT:** Op-stratified, in-expression edits (J) sit midway between inert (I) and AST-changing (D): J-J = 0.53-0.59 vs I-I = 0.87, D-D = 0.29. Whitespace inside the expression is inert (loadings 0.79-0.86, same as I). Parenthesising a single operand is partially non-inert (j_parens_first loading 0.40, j_parens_second 0.66) while parenthesising the whole expression is nearly inert (d_parens 0.77). Neither "adjacency" nor "semantic change" predicts this ordering; "rarity of the resulting code form" fits the observed pattern but is untested.

Per-J-pert detail (sorted by A-correlation, with review annotations):
- j_space_after_op: A=+0.820, loading 0.86 — INERT
- j_parens_second: A=+0.570, loading 0.66
- j_unary_first: A=+0.530 — MISCLASSIFIED (adds AST node, belongs in D)
- j_space_before_op: A=+0.433 — CONFOUNDED by `//`-comment artifact on 15 cells
- j_spaces_both: A=+0.397 — PSEUDO-REPLICATE of j_space_before_op (rho 0.957)
- j_parens_first: A=+0.351, loading 0.40 — MOST DISRUPTIVE (rare code form `(3) + 5`)

**NEW FINDING: `//`-comment disambiguation.**
`a // b` (two spaces before `//`) is read on the bare surface as `a` followed by a C-style comment; the `# Python code` header restores floor division. Distance 0.12-0.32 on all 15 `//` cells vs ~0.02 elsewhere. Reproduced on 8/8 manually checked `//` cells. Clean, large (10x), reproducible case of surface context disambiguating programming language. Worth its own entry and investigation.

**READOUT-CONDITIONALITY CAVEAT:** For the same pert, cell ranking under the two R30a/R30b readouts correlates only 0.04-0.72 (median ~0.43). Cell-ranking vector is readout-specific; every transfer-rho number in this program is conditional on the exact `print(x)\n# Output: ` suffix.

TOKENIZATION ANALYSIS (zero-cost, raw data still valid):
Qwen3-0.6B tokenizer:
- baseline: ['x', ' =', ' ', '3', ' +', ' ', '5']
- j_space_before_op: ['x', ' =', ' ', '3', ' ', ' +', ' ', '5']
- j_space_after_op: ['x', ' =', ' ', '3', ' +', ' ', ' ', '5']
- j_parens_first: ['x', ' =', ' (', '3', ')', ' +', ' ', '5']
Note: before/after asymmetry on non-// cells is SMALL once `//`-comment artifact removed (rho 0.81 between the two excl //). The large before/after asymmetry originally reported was the `//` comment artifact, not a token-context effect.

J-D cross-group (F4 from review): J-D (+0.304) < J-J (+0.413) AND D-D (+0.392).
If J and D were one class, J-D should equal both. One-factor model: J and D are separately heterogeneous groups with similar average loadings, not a shared class.
d_parens (loading 0.76) correlates more with i_extra_space (0.75) than most D perts.

R30b vs R30a: R30a (wrong prompt) inflated J-J to +0.619 and deflated I-I to +0.538.
Corrected prompt shows J intermediate, not J≈I or J≈D.

74. **SmolLM2-360M R30b replication — LOW ACCURACY, UNRELIABLE (2026-09-20).**
SmolLM2-360M replication of R30b completed. Accuracy: 55.96% (BELOW 80% threshold).

| Group | SmolLM2-360M | Qwen3-0.6B (corrected) |
|---|---|---|
| A-A | +0.669 | +0.838 |
| I-I | +0.812 | +0.858 |
| J-J | +0.621 | +0.413 (pooled) / 0.53-0.59 (op-strat) |
| D-D | +0.412 | +0.392 |

midpoint(A,D) = 0.540. J-J (0.621) > midpoint → J leans INERT in SmolLM2-360M.
Consistent with Fable-corrected Qwen3 result (J intermediate, leaning inert).
**CAVEAT:** 55.96% accuracy = model is near-chance on many cells. All group rhos are
unreliable as perturbation effects are diluted by guessing. This data is noted but
NOT used as evidence for any claim. Fable review correctly warned against replicating
this design on a model below accuracy threshold.

75. **Independent verification of Fable review claims (2026-09-20, zero-cost).**
Recomputed all key Fable statistics from saved R30b dist_matrix:
- `//` artifact: 12.4x ratio CONFIRMED (Fable: 10x, exact: 12.4x on // cells)
- Op-stratified J-J = 0.534 CONFIRMED (Fable: 0.534)
- j_spaces_both pseudo-replicate: rho 0.957 CONFIRMED
- Excluding // cells: J-J = 0.536 CONFIRMED
- d_parens A-loading = 0.674 (Fable: 0.76-0.77 via different metric, both near-inert)
- j_space_after_op loading = 0.877 (inert) CONFIRMED
- j_parens_first loading = 0.361 (most disruptive) CONFIRMED
All Fable claims verified. Corrections to NOTEBOOK 73, STATE.md, EXPERIMENTS.md (40),
and ledger 940 are justified.

76. **R31 tokenization pre-analysis (2026-09-20) — PARTIALLY WITHDRAWN after R31 Fable review.**
Tokenization check of R31 candidates was correct (s_no_spaces changes operator token
from ' +' to '+', etc). But the three-way discrimination predictions were based on
POOLED per-pert loadings — the same pooling defect the R30b review corrected at group
level. Fable R31 review showed: op-stratified, d_parens (0.602) ≈ j_parens_first (0.564)
≈ j_parens_second (0.575), CIs all overlapping. "Whole-expr parens nearly inert,
single-operand parens most disruptive" does NOT exist within any operator. The pooled
gap was between-operator block reordering.
SURVIVING: tokenization data is raw and correct; the hypothesis table needs restatement
with op-stratified loadings as the target. s_no_spaces remains the most informative
new datum per the Fable review.

77. **Per-pert loading analysis (2026-09-20) — WITHDRAWN (pooling artifact, same defect).**
The "D-group positional gradient" (d_parens 0.674 → d_temp_var 0.304) was also a pooling
artifact. Op-stratified (strat4) loadings from Fable R31 review:

| pert | pooled | strat4 | betwOp |
|---|---|---|---|
| d_parens | 0.632 | 0.602 | 0.55 |

| d_int_cast | 0.505 | 0.417 | 0.64 |

| d_add_zero | 0.485 | 0.391 | 0.13 |

| d_cond_true | 0.400 | 0.568 | 0.15 |

| d_zero_plus | 0.299 | 0.204 | 0.46 |

| d_temp_var | 0.262 | -0.013 | 0.59 |

Strat4 order DIFFERS from pooled (d_cond_true jumps from 0.400 to 0.568). d_temp_var at -0.013 = cell rankings are essentially random within operators. Some "low-loading" perts (d_cond_true, d_add_zero) are low only because they change which OPERATOR's cells are most header-sensitive (betwOp 0.13-0.15), not the within-operator ranking. "Autoregressive positional cascade" hypothesis WITHDRAWN — was explaining a between-operator artifact. The real structure is a THREE-LEVEL PLATEAU:

1. Outside-expression edits: strat4 0.77-0.85
2. AST-preserving in-expression edits: strat4 0.53-0.60 (flat plateau)
3. Computation-changing edits: strat4 -0.01 to 0.57 (wide spread)

78. **Fable R31 adversarial review — DESIGN REJECTED (2026-09-20).**
Full review at scratchpad/r31_fable_review.md. Key findings:
(1) The ordering R31 exists to explain is a pooling artifact (see entry 77).
(2) 15/20 perts are re-runs (fp32 CPU deterministic, zero information).
(3) "Rarity" not operationalized; model-surprisal data already disfavors it (3x surprisal range → flat strat4 loadings 0.53-0.60).
(4) All AST-preserving in-expression edits sit on a plateau at 0.53-0.60.
(5) Between-operator block reordering, not within-operator cell ranking, drives the pooled "disruptive" appearance of some perts (betwOp 0.13-0.23).
(6) Token-count change correlates -0.65 with strat4 loading among in-line perts.

Recommended replacement:
Stage 0 (zero cost): within/between decomposition for all 36 R30b perts.
Stage 1 (~3 min CPU): only 5 new forms (s_no_spaces, s_space_before_only, s_space_after_only, p_per_operand, p_double) + 2 anchor re-runs, merged into R30b. Record per-(cell, form) line surprisal. Pre-register: H_plateau (all in [0.45,0.70]), H_rarity (surprisal-loading correlation over ~13 in-expression forms), two matched contrasts (p_double vs p_whole_expr, s_no_spaces vs s_space_after_only), and explicit ambiguity rule (differences < 0.25 → undecidable, expand cells instead of interpreting).
Stage 2 (only if needed): 36 cells/operator to halve CIs.

`//`-artifact check: s_no_spaces/s_space_before/s_space_after are all 15/15 correct on `//` and `-` cells, distances at baseline. Artifact requires >=2 spaces before `//`.

79. **Stage 0 within/between decomposition — all 36 R30b perts (2026-09-20, zero-cost).**
Computed strat4 loading, betwOp, per-operator loadings with bootstrap CIs for all 36 perts. Saved to experiments/results/transfer_spectrum/r30b_decomposition.json.

THREE-LEVEL PLATEAU CONFIRMED (strat4 values, sorted within group):

| Level | Group | strat4 range | betwOp range |
|---|---|---|---|
| Outside-expression | A, I | 0.79-0.95 | 0.77-1.00 |
| AST-preserving in-expr | J | 0.50-0.87 | 0.20-1.00 |
| Computation-changing | D, V | -0.01 to 0.66 | -0.03 to 0.77 |

| Own-line semantic | O | 0.22-0.92 | 0.31-0.94 |

KEY INDIVIDUAL FINDINGS:
- j_space_after_op: strat4 0.866 — nearly A-level. Adding space AFTER operator barely disrupts within-operator cell ranking. betwOp=1.000 (perfect operator-block match with A).
- j_parens_first (0.633) ≈ j_parens_second (0.640) ≈ d_parens (0.655): CIs all overlap. Confirms Fable R31 review: whole-expr vs single-operand parenthesisation indistinguishable.
- j_space_before_op: strat4 0.655 but CI [0.35, 0.87] — wide due to //-comment artifact inflating one operator's distances. betwOp=0.543 (moderate block reordering).
- d_temp_var: strat4 = -0.007 — within-operator cell rankings are random noise. But betwOp=0.657 — the BETWEEN-operator structure is preserved. So temp_var destroys fine-grained cell ranking while preserving which operators are "harder."
- d_cond_true: strat4 0.581 — looks MODERATE within operators. But betwOp=0.086 — near-zero block structure. Opposite pattern to d_temp_var. In pooled stats both look "disruptive" for different reasons.

J-group is NOT flat at 0.53-0.60 as Fable estimated — actual range is 0.50-0.87. j_space_after_op is a genuine outlier at 0.87 (nearly A-level). The LOWER J perts (j_unary_first 0.50, j_spaces_both 0.59, j_parens_first 0.63, j_parens_second 0.64) do cluster in 0.50-0.64. Revised plateau definition: AST-preserving in-expression edits cluster at 0.50-0.66 EXCEPT space-after-op which is near-inert.

80. **R31 Stage 1 — 5 new spacing/paren perts (2026-09-20, Qwen3-0.6B-Base, 226s CPU). CORRECTED post-Fable adversarial review (5/6 claims fall, 1 survives).**
69 cells × 7 perts (5 new + 2 anchors). Overall accuracy 98.8%.
Anchor bit-identity check: max|diff| = 4.3e-6 (fp32 numerical noise, not a failure).
Saved: experiments/results/transfer_spectrum/r31_stage1_qwen3_0_6b_base.json.
Fable review: scratchpad/r31_stage1_fable_review.md.

RESULTS (sorted by strat4, CIs CORRECTED to cell-level stratified bootstrap):

| pert | strat4 | cell-CI | betwOp | surp | acc | + | - | // | % |
|---|---|---|---|---|---|---|---|---|---|
| a_empty_anchor | 0.924 | [0.79,0.97] | 1.000 | 2.41 | 1.00 | .94 | .98 | .96 | .82 |
| s_space_before_only | 0.671 | [0.47,0.82] | 0.886 | 3.62 | 1.00 | .97 | .73 | .88 | .10 |
| s_no_spaces | 0.670 | [0.45,0.81] | 0.657 | 3.24 | 0.99 | .74 | .87 | .78 | .29 |
| d_parens_anchor | 0.655 | [0.41,0.80] | 0.486 | 2.47 | 1.00 | .70 | .53 | .64 | .76 |
| p_per_operand | 0.606 | [0.35,0.76] | 0.200 | 2.90 | 0.99 | .58 | .47 | .62 | .75 |
| s_space_after_only | 0.469 | [0.22,0.65] | 0.829 | 3.28 | 0.94 | .71 | .63 | .65 | -.10 |
| p_double | 0.279 | [0.01,0.48] | -0.600 | 3.48 | 1.00 | .21 | .03 | .59 | .30 |

ANCHOR CEILING (corrected): a_empty 0.924 is self-inflated (it's in its own A-group reference). Leave-one-out: 0.881. True A-A pairwise within-operator mean: ~0.80 (+0.81, -0.88, //0.86, %0.64). All "plateau vs inert" gaps should be measured against ~0.80.

ORIGINAL CIs (operator-level bootstrap, 35 distinct outcomes) were WRONG — both too narrow when operators agreed and too wide when one operator was an artifact outlier. Cell-level CIs above are from Fable's recomputation.

PRE-REGISTERED HYPOTHESES:
- H_plateau (all 5 in [0.45,0.70]): **REJECTED** — p_double at 0.279, and with `%` artifact removed s_space_before_only reaches 0.86 (above plateau ceiling).

- H_rarity: **NOT TESTED AS REGISTERED.** The registered test was 13 forms with partialling on |token delta|; only 5 forms were used, no partialling. n=5 Spearman cannot reach p<0.017 even at rho=±1. The two registered matched contrasts both went RARITY'S WAY: p_double < d_parens (P=1.000), s_no_spaces > s_space_after_only (strat3 diff +0.14, CI [-0.01,+0.32]). Evidence: MIXED, UNTESTED. Not dead.
- H_token_context Contrast 1 (p_double vs d_parens): **CONFIRMED** — paired cell-level bootstrap diff -0.376, CI [-0.60,-0.15], P(diff≤0)=1.000.
- H_token_context Contrast 2 (s_no_spaces vs s_space_after_only): **UNDECIDABLE** on strat4; on strat3 (clean, excluding `%`): diff +0.14, CI [-0.01,+0.32].
- Contrast 3 (s_no_spaces vs s_space_before_only): **NOT PRE-REGISTERED.** Executed post-hoc. On clean operators: -0.06, CI [-0.26,+0.10]. Indistinguishable.

SURVIVING FINDING: p_double `((expr))` has lower within-operator loading than d_parens `(expr)` and p_per_operand `(a)op(b)`. Survives cell-level paired bootstrap and artifact removal (strat3 diff -0.35, CI [-0.61,-0.08]).

WITHDRAWN (5 claims):
1. "Destroys +/- while preserving //" — per-operator loadings have n=15 each; Fisher-z CIs: + [-.37,.67], - [-.52,.56], // [.07,.85], % [-.29,.72]. The //-vs-+ and //-vs- differences are within 1 SE. Ordering of four noisy numbers read as structure.
2. "// resilience from disambiguation, robust to nesting" — `-` is the MOST header-sensitive operator (34.6 mean dist) with zero disambiguation. When disambiguation IS the effect (`%` artifact), loadings are LOWEST, not preserved. No `//` effect to explain.
3. "Token-context refuted: s_no_spaces ≈ s_space_before_only" — the 0.670≈0.671 equality is manufactured by the `%` artifact. Clean (strat3): 0.80 vs 0.86, both near-inert ceiling. Can't conclude either way. Contrast was not pre-registered.
4. "betwOp = -0.600 inverts operator structure" — Spearman over n=6 points. Exact permutation p=0.24. Non-significant.
5. "Rarity is dead" — n=5 test had no power. Registered test never run. Two matched contrasts went rarity's way. Evidence is mixed, not conclusive in either direction.

LEADING ALTERNATIVE (from Fable review): HEADER SHIELDING (M-shield). Parens shield the expression from the header, depth-monotonically. Per-operator mean distance and SD for `-`: A=33.6(10.0), (e)=24.4(5.5), ((e))=14.0(2.1). This is the header effect being REMOVED on the operator that had the most of it, not cell rankings being "reordered." The loading drop follows from SD compression — when all cells have similar (low) distances, the ranking is whatever noise remains near the floor.

`%`-DISAMBIGUATION ARTIFACT (confirmed, same class as `//`-comment artifact): `<digit>%` with no leading space triggers percent-literal reading ("four percent") on bare surface. Header cures it. Contaminates s_no_spaces and s_space_after_only on `%` cells (7-15x distance inflation). Must be excluded. With `%` excluded: s_no_spaces strat3=0.80, s_space_after_only strat3=0.66, s_space_before_only strat3=0.86 — spacing perts sit at or near the inert ceiling. The "plateau" for spacing perts was an artifact.

R32 NESTING DEPTH FOLLOW-UP (zero-cost except p_triple, ~30s CPU):
Depth series: expr(0.924) → (expr)(0.655) → ((expr))(0.279) → (((expr)))(0.287).
FLOOR at depth 2 (p_triple 0.287 ≈ p_double 0.279, diff +0.007). NOT monotonic.
M-shield prediction (mean distance decreases monotonically) holds through depth 2 on

header-sensitive operators (`-`: 33.6→24.4→14.0; `%`: 24.7→15.6→11.8) but REVERSES slightly at depth 3 (`-`: 14.0→15.9; `%`: 11.8→13.0; `+`: 14.4→16.7; `//`: 14.9→15.5). All 4 operators show small mean distance INCREASE from d2→d3. The floor is real but it is not pure monotonic compression — something additional happens at depth 3. Tokenization: ` (((` and `)))\n` are each single Qwen3 tokens (same as ` ((` and `))\n`), so all depths ≥1 have the same token count (8). The floor is not a tokenization artifact.

81. **R33 zero-cost re-analysis — artifact exclusion, cell-level CIs, clean landscape (2026-09-20).** Implements all Fable review recommendations. Zero cost (reads saved data only). Saved: experiments/results/transfer_spectrum/r33_reanalysis.json.

ARTIFACT EXCLUSION RULE: exclude (pert,op) blocks where median distance > 3x A-median. Catches: j_space_before_op/`//`, j_spaces_both/`//`, s_no_spaces/`%`, s_space_after_only/`%`, d_temp_var/`+,//,%`. Nothing unexpected. Rule catches exactly the known disambiguation artifacts.

A-A PAIRWISE CEILING (corrected): +0.808, -0.880, //0.861, %0.635. Mean ~0.80.
LOO anchor: a_empty 0.881 (self-included 0.924).

CLEAN LANDSCAPE (artifact-excluded strat4):
Level 1 INERT (>0.80): all A-group, I-group, j_space_after_op (0.866), j_space_before_op (0.810, was 0.655 with `//` artifact), s_no_spaces (0.798, was 0.670 with `%` artifact). ALL spacing perts are near-inert once artifacts excluded.
Level 2 PARTIAL (0.55-0.80): a_identity (0.790), o_parens (0.745), j_spaces_both (0.714), s_space_before_only (0.671), s_space_after_only (0.660, was 0.469), d_parens (0.655), j_parens_first/second (0.63-0.64), p_per_operand (0.606), v_parens (0.587), d_cond_true (0.581).
Level 3 BELOW PLATEAU (<0.55): p_double (0.279), p_triple (0.287). ONLY double/triple parens.

KEY INSIGHT: The "three-level plateau" from R30b was an artifact of the `//` and `%` disambiguation artifacts inflating pooled statistics. With artifacts removed:
- Spacing changes are INERT (whitespace doesn't matter)
- Single-paren forms span 0.58-0.66 (the real "plateau")
- Only double/triple parens (~0.28) are genuinely below
- The organizing variable is parenthesisation depth, not "AST-preserving in-expression edit"
- Fable review's "adds bracket tokens vs changes whitespace" distinction is confirmed

PAIRED CONTRASTS (cell-level bootstrap, 2000 iterations):
p_double - d_parens: -0.364 CI[-0.601,-0.156] P(≤0)=0.999 (confirmed)
p_double - d_parens (strat3, excl %): -0.338 CI[-0.600,-0.079] P(≤0)=0.995
p_triple - p_double: +0.013 CI[-0.226,+0.255] (floor confirmed, CI spans 0)
p_triple - d_parens: -0.355 CI[-0.612,-0.078] P(≤0)=0.992
s_space_before - s_space_after (strat3): +0.207 CI[+0.031,+0.425] P(≤0)=0.009
s_no_spaces - s_space_before (strat3): -0.063 CI[-0.256,+0.113] (indistinguishable)

H_RARITY (PARTIAL): n=5 R31 forms only, rho=0.100, p=0.873. STILL INCOMPLETE — need R30b J-group + extra surprisal (~1 min CPU) for the registered 13-form test.

82. **R33b H_rarity as registered — 13-form test (2026-09-20, ~63s CPU).** Computed line surprisal for 8 R30b in-expression forms (j_space_before_op, j_space_after_op, j_spaces_both, j_parens_first, j_parens_second, j_unary_first, d_parens, v_parens) + 5 R31 forms = 13 total. 69 cells × 8 forms × 1 forward pass = 552 forward passes, 63s CPU. Saved: experiments/results/transfer_spectrum/r33b_r30b_surprisal.json.

H_RARITY (13 forms, raw Spearman): rho=-0.196, p=0.522. NOT SIGNIFICANT.
H_RARITY (13 forms, partial on |token delta|): rho=-0.151. WEAKENED further.
Registered threshold: rho ≤ -0.6 with CI excluding 0. FAILS.

The sign is correct (negative: higher surprisal → lower strat4, consistent with rarity predicting that rarer forms have lower loadings). But the effect is weak and not significant.
Rarity is INCONCLUSIVE: evidence is genuinely mixed.
- Rarity-supportive: p_double (high surprisal 3.48, lowest strat4 0.28) fits.
- Rarity-contradictory: j_unary_first (highest surprisal 3.99, strat4 0.50 not lowest).
- j_space_after_op (lowest surprisal 3.07, highest strat4 0.87) fits rarity direction.
- Scatter is wide. n=13 is underpowered for rho=-0.20.
The registered H_rarity test is now COMPLETE. Verdict: INCONCLUSIVE.

83. **Fable R34 design review — R34 ABANDONED (2026-09-20).**
Review: scratchpad/r34_design_review.md. Verdict: DO NOT RUN AS DESIGNED.
KEY FINDINGS FROM EXISTING C-GROUP DATA:
(1) "Python evidence" is NOT the operative variable. `pass` (Python keyword) RAISES header distance by 50% (33.6→49.6 on `-`). `# start` (comment, ambiguous language) COLLAPSES it hardest (4.5). The prefix effect tracks "first-line-is-a-comment", not P(Python|prefix).
(2) The paren floor (~14) is 3× ABOVE the comment-prefix floor (~4). If parens "shielded" the header, the paren floor should match the redundancy floor. It does not.
(3) p_double is NOT a compressed copy of A. Pearson(p_double, A-mean) = 0.105 over 60 cells. d_parens = 0.716. p_double is genuinely REORDERED, not "A scaled down."
(4) M-shield as stated (compression → noise → low strat4) FAILS quantitative check: simulation with compression ratio 0.4 + constant noise predicts strat4≈0.62; observed 0.28. p_double within-`-` SD (2.1) < A-A noise SD (3.3) → noise compressed WITH signal → Spearman should not have dropped at all. p_double's low strat4 is genuine reordering.
(5) `c_comment_before` at mean distance ~4 (3× below p_double) keeps strat4 0.54. "Near floor → noise" directly contradicted.
(6) Before-line edits are NOT inert — every C-group pert has strat4 0.37-0.61.
(7) The R34 hypothesis labels were INVERTED.

M-SHIELD AS STATED IS REFUTED by the existing C-group data + the Pearson check.
Need a new account of why p_double has low strat4. Leading candidates:
- Bracket-token identity effect (` ((`/`))\n` are rare tokens that change representation)
- Genuine representation change from double parenthesisation
- Some combination of compression + reordering specific to bracket tokens

RECOMMENDED REPLACEMENT (from Fable):
(a) Zero-cost C-group re-analysis as prefix family
(b) 2×2 factorial: {none, `# start\n`} × {e, ((e))} — 3 of 4 cells exist, one new (~30s)
M-redundancy predicts: prefix+parens ≈ prefix alone (parens redundant under prefix)
Repr-change predicts: prefix+parens ≠ prefix alone (parens still shift cell pattern)
(c) Sign-flip control: `# C code\n` — language-evidence predicts distance UP; first-line-comment predicts COLLAPSE. Maximally diagnostic.

**Next:** Zero-cost C-group re-analysis (Pearson vs A, per-op mean distance ratio). Then implement 2×2 factorial + sign-flip control (~60s CPU).

84. **Zero-cost C-group re-analysis — prefix family characterization (2026-09-18).**

6 models, balanced kill data. Script: scratchpad/cgroup_reanalysis.py. No model runs.

C-GROUP IS NOT INERT. CC transfer rho (within-group Spearman):

Qwen3-1.7B: 0.458, SmolLM2-1.7B: 0.805, SmolLM2-360M: 0.640,

Qwen3-0.6B: 0.173, Phi-1.5: 0.686, StableLM-2: 0.496.

Compare AA: 0.696-0.944 across same models. CC << AA in 5/6 models.

AC cross-group: 0.271-0.757. Prefix perturbations probe different cell structure than suffix.

TWO-TIER SPLIT by prefix type (C/A distance ratio, cross-model median):

Tier 1 — COLLAPSE header distance:

c_desc_comment (`# Description\n`): 0.12-0.37x A (most collapsing)

c_comment_before (`# start\n`): 0.12-0.66x A

c_assert_before (`assert True\n`): 0.17-0.79x A

Tier 2 — MATCH or RAISE header distance:

c_dead_var_before (`_z = 0\n`): 0.27-1.24x A

c_pass_before (`pass\n`): 0.25-1.77x A

c_newline_before (`\n`): 0.35-3.73x A (most amplifying)

ORGANIZING VARIABLE: "first line is a comment" → collapse; "first line is code" → no collapse.

This confirms entry 83(1): the operative variable is comment-vs-not-comment, not

P(Python|prefix). A bare newline (no Python evidence) RAISES distance 1-3.7x in 4/6 models;

a `pass` statement (strong Python keyword) raises it 1.4-1.8x in Qwen3 models.

PEARSON VS A-MEAN (cell-ranking preservation):

Comment prefixes have variable Pearson with A-mean: 0.17-0.93 (model-dependent).

c_dead_var_before has consistently high Pearson (0.31-0.96): preserves A-group cell ranking.

c_newline_before: high Pearson in 4/6 models (0.48-0.92): same cells are fragile.

Interpretation: comment prefixes can REORDER cell vulnerability (change which cells are

fragile); code prefixes preserve the ranking but may scale the magnitude.

MODEL HETEROGENEITY:

Phi-1.5: most stable — all C Pearson>0.63, CC rho=0.686. C behaves like scaled A.

Qwen3-0.6B: most heterogeneous — CC rho=0.173, c_desc_comment Pearson=-0.228.

C-group probes genuinely different structure in this model.

SmolLM2-1.7B: highest CC (0.805) and AC (0.757) rho — best C→A transfer.

PER-OPERATOR PATTERNS:

The `//` (integer division) operator consistently shows the largest C/A distance ratios

across models (especially for c_newline_before and c_dead_var_before). The `%` operator

is similarly amplified. This is the same operator-specificity seen in the main kill data.

IMPLICATION FOR PERTURBATION HIERARCHY: C-group sits BETWEEN A-group (inert suffix) and

D-group (expression modification). CC rho < AA rho confirms C is more heterogeneous than A.

The two-tier split means position alone doesn't determine C-group behavior — what the

prefix IS (comment vs code) matters. This is the first clear case where CONTENT of a

non-expression perturbation affects behavior above noise level. The hierarchy is:

A (inert suffix) → C-comment (comment prefix, collapses) → C-code (code prefix, variable)

→ D (expression modification, heterogeneous). Position is necessary but not sufficient.

85. **Fable adversarial review of domain universality design — REVISE (2026-09-18).**

Review: scratchpad/fable_universality_v2.md. VERDICT: REVISE, not proceed as designed.

KEY FINDINGS:

- CRITICAL-1: 4/6 predictions are tautological. AA >> DD is a property of perturbation position (causal masking), not domain. Will trivially generalize.
- CRITICAL-2: Breakthrough ceiling for generalization is LOW. "Position matters for transformers processing code" is expected since Vaswani 2017, not field-changing.
- MAJOR-2: D-group is not domain-portable. Identity operations differ fundamentally across domains (int() on int vs str() on string vs roundtrip vs bool cast).
- MAJOR-3: C-group two-tier split (entry 84) IS the diagnostic prediction — it tests content distinction (comment vs code), not just position.
- MAJOR-4: Test alone doesn't meet "breakthrough or nothing." Needs pairing with theoretical advance (formal model of why comment/code processing differs).

REVISED RECOMMENDATIONS:

1. Primary question: "does C-group comment/code split generalize?" (non-tautological)
2. Reduce to 20 cells × 2 domains × 3 models (~2880 forward passes, ~5-8 min CPU)
3. Keep only portable D-perts (d_parens, d_cond_true, d_temp_var, d_double_parens)
4. Pre-register C-group split: comment < 0.5x A-mean, code > 0.5x A-mean
5. Run G0 first as separate diagnostic
6. State breakthrough path: universality → C-group → formal model → testable predictions

86. **Droid strategic review — construct-validity kill test (2026-09-18).**
Review: scratchpad/droid_strategic_r1.md.

CENTRAL CONCERN: The hierarchy may be a property of the `# Python code\n` probe, not of perturbations in general. The measured quantity is distance(bare, header) under each perturbation — NOT distance(unperturbed, perturbed). The C-group comment/code split could be an interaction with the header: comment prefixes make bare and header conditions more similar (both start with #), code prefixes make them structurally different.

RECOMMENDATION: Run neither domain universality nor sign-flip as the main experiment.
First run a CONSTRUCT-VALIDITY KILL TEST:

- Measure perturbation distance DIRECTLY: cosine(unperturbed, perturbed)
- Do this on both bare and header-present surfaces separately
- Use small representative set: inert suffix, comment prefix, `# C code` prefix, code prefix, blank-line prefix, expression rewrite
- Full-logit and answer-level readouts, multiple model families

DECISION RULE:

- If hierarchy FAILS direct measurement: reframe as "contexts modulate response to a Python-language header." Correct public claim. Close program.
- If hierarchy SURVIVES: evidence for probe-independent susceptibility structure.
Only then run domain test.

BREAKTHROUGH ASSESSMENT: None of these experiments is field-changing alone. Only path is a predictive invariant: rule specified before observation that predicts unseen perturbation effects across domains/readouts/models, beating token frequency, length, position, and syntax baselines.

SYNTHESIS OF BOTH REVIEWS:

Fable says: C-group split is the diagnostic prediction, not A/D gap (tautological).

Droid says: Before testing universality, test construct validity — is the hierarchy probe-independent? Both agree: breakthrough ceiling of current designs is low. Both point toward the same deeper question: is there a probe-independent perturbation sensitivity structure, and can it be predicted from first principles?

NEXT: Revise design to address construct validity first (Droid), then C-group universality (Fable), with breakthrough path stated explicitly.

---

### User-requested paused closeout — 2026-09-14

Research is paused through S65; no new experiment is queued. Start at [docs/HANDOFFS.md](docs/HANDOFFS.md) on return. S58 supplies a narrow teaching positive; S62 does not justify richer feature access on its panel; S63/S64 separate temporal contributor evidence from consumer/memory effects. S65 completes a three-case supplied-revision diagnostic, but zero capital prerequisites are correct (18/18 responses terminate). All outputs and first-attempt failure are preserved. The natural-question prerequisite remedy is unrun. Mission/philosophy remain unchanged and unfinished; no cumulative acquisition or native law is established.

### Strategy routing consolidation — 2026-09-14

S53's consumer/access distinction, S54's admission-history analysis and S55's global-editing/resource check are complete in canonical theory and the ledger. The current next-work boundary now indexes remaining empirical decisions and completed arguments rather than repeating chronological routing. No result or closure is changed; no new computation is counted.

## Strategy/discovery checkpoint and history — 2026-09-14

S53 selects reaction-sensitive structural requests as a concrete candidate. Source study keeps mixed inputs, recorded-reference limits and MIT's missing stereochemistry explicit. A four-case source illustration is manually checked, with no parser/model run. The reviewer corrected query-count economics: more queries can favor a graph decoded once. Next define a limited consumer and attribution comparison; no training.

S52 checks assimilation through independent ports and the existing per-request consumer loss. KL decomposition identifies its marginal target; two-round review chooses objectively assessable later uses instead of imitating donor randomness. A reusable sufficient-record predictor is the cheap comparator; two anticipated answers alone do not show operation acquisition. No empirical count changes.

Fresh periodic review around 15:30 UTC followed62f85fe and separate entropy checking. It corrected a possible conflation of unchanged connected addition with shared updates that can forget old uses. S50 replay is conditional on modifying relevant dependencies and is not necessary if induced-input component replay already suffices. S51 works one depth-boundary error and a direct repair hypothesis; it supplies no measured reason for shared adaptation. Next choose a specific testable benefit, not another model merely because it is downloadable. Independent subagent review, not a real CLI audit. No empirical count changes.

S51 defines a useful category/depth pixel selection and verifies one raw depth

interface. No learned alignment is required to express the direct route. A limited source check did not bind the actual trained AB endpoint, so local execution of that exact acquisition episode closes. Keep source findings; pivot the approach.

S50 now supplies the concrete reference episode: semantic acquisition into a spatial model, old-task evaluations and useful joint behavior. Attribution is limited by unmatched guidance, semantic comparator and resolution. The next question was retaining the achieved interaction during another admission; S50's worked replay proposal now records that dependency, and S51 closes this exact local episode after its endpoint check. Original-input retention alone does not settle interaction retention. No local reproduction.

**Latest user restart, 2026-09-14:** mission fixed, approach flexible. S37 and its unavailable CLI audit are parked. S38 now separates donor target construction, student intervention training, pretrained contribution and mechanism interpretation. Primary sources and independent strategy reviews inform the comparison. S39 then found actual cross-model communication implementations and a concrete receiver-prompt confound. S40 identifies a constructive separately prepared/joint use precedent, with unbound exact joint-run provenance in the checked release. S41 one-read attention algebra is independently checked but kept diagnostic; it does not justify a new measurement program. S42 separates response-generator, embedding-teacher and predictor roles; conditional prefix reuse is checked but not implemented. S43 read32 published answers on16 matched queries, finding one clean correction amid shared errors and unfinished targets. Slice closed without expansion; no training or model run selected.
S44-S46 clarified conditional evidence selection and direct teaching. S47 ran a 107-line lexical diagnostic on four usable pairs among five selected reports: 7/8 adequate whole-abstract selections,8/8 with RESULTS filtering, one mixed-quality tie remaining. Closed without model probe or expansion. No acquired artifact.
S48 checks the distinction between portable directions and read/write operations; shared calibration evidence must also benefit the direct-learning comparator. Readout transfer without new task calibration does not establish reusable updates.
S49 verifies the missing new-question input in a reconstruction path and a separate prepared memory consumer with actual later-prompt conditioning. Their combination remains untested; source multi-span reuse required extra training.
Continuation identifies a trained reasoning comparator and a no-alignment control that retains rationale access. Shared-model targets remain dynamic despite detachment; a small-checkpoint download was rejected as low leverage after two-round review. Consumer teaching must exercise intended later requests.
No commutator apparatus or model run is selected. Older checkpoints below are historical where they conflict with this current allocation.

**Mission-coverage consolidation, September 14:** current routing now requires supported prior A, useful new B and a joint use; repeated requests over one memory are not successive acquisition. Recent interface findings change implementation choices without supplying that episode. Information novelty is not required for useful contribution. The compact canonical map separates precedents from missing

local evidence and supersedes the accumulated routing diary above.

The enduring question is what a denizen of latent space needs for identity,
movement, effort, maps and reusable laws. Cumulative capability acquisition is
one direction within that philosophy. Connected growth and assimilation after
donor removal are separate branches. User authorization at 19:45 UTC permits
sustained strategy, source research and bounded CPU probes, not system-building.
No cumulative artifact, causal graft, encoder-reasoning or cost advantage is
established. Closed prior lines stay closed; no run follows from documentation.

**Earlier model-forward checkpoint:** S26's single CPU continuation run is complete, with
independent audit complete: e1044-e1045. Primary and independent pair recovery were both 0/16;
second-site recovery was 2/16 for both, versus cyclic content control 3/16.
The first prediction was correct on only 1/16, capping unrevised pair recovery
below the locked .10 gain threshold even with a perfect second step. Close this
procedure on this panel; this weak-proposal result does not exclude composition
with competent inputs or establish that a learned exporter helps. No rerun,
threshold change or new selection follows. [Raw result](experiments/results/encoder_continuation_v1/result.json)
retains probabilities, counts and hashes; the completed audit receipt is in the ledger.

**Current priority reassessment:** S36's compatibility-first selection is
superseded. Fresh review first preferred S28's evidence-selection comparison;
the second round accepted S37's objectively scored causal-teaching preflight.
That round could not read local files because its shell failed. The third review
read the lock and runner and issued conditional GO after supervisor enforcement,
complete tokenizer/alignment assertions, per-batch checkpoints and reporting fixes.
S37 then made two bounded execution attempts, both with zero scored forwards:
a 180 s compute-phase timeout and an HTTP-compression download bug at metadata
alignment. Raw attempts and diagnostic hashes are retained. Downloader and owned
cache metadata are corrected offline; no third run occurs in this allocation.
No donor competence, recipient headroom or intervention result exists. Two fresh real CLI audit attempts could not read files; their audits are incomplete.
Separate collaboration custody checks verified raw counts and hashes; ordinary/text-counterfactual teaching remains
the required comparator if a future eligible preflight funds teaching. Receipts
live in internal/codex_transcripts, exact failures in the ledger and canonical S37.
S34 and previously closed scientific probes remain deferred/closed.

**Accounting and custody:** 1065 apparatus / 0 artifact-bearing code lines
(98 + 119 + 204 + 207 + 330 + 107), six probe blocks / zero construction rounds;
S37 has two failed attempts and zero scored forwards; 15 total scored forwards,
no GPU or training. Strategy authorization supersedes construction to repair the
ratio. Root alone writes boards after stale-session ID collisions; integrity
entries restored as e1011–e1012. Mission synthesis retains its hang workaround.
Fresh real CLI result audits and design dialogues have distinct receipts below;
fourth periodic review completed around 02:40 UTC on September 14 (e1086-e1087)
after consolidation at e72f83d and a separate entropy review. Strategy map review completed around 03:34 UTC
(e1095–e1096); retain the two-hour cadence during subsequent substantive research. The user-requested S37 reassessment supersedes S36 priority; the canonical
next-work boundary controls execution readiness.

Detailed mathematics/source readings live in
[canonical theory](theory/CUMULATIVE_CAPABILITY_ACQUISITION.md); exact results,
corrections and receipt hashes remain in the [ledger](experiments/ledger.jsonl)
and [experiment log](experiments/EXPERIMENTS.md).

### 23:03–23:34 UTC: typed-contract closure and one continuation probe

The second review closed S24's purchasing contract: authoritative scoped import
and its specified calculator already supply fresh consequences and B retention.
Producer reliability/rechecking would need an actual scoped source and semantic
port; do not invent a learned receiver or extend this hypothetical case.
Two fresh CLI direction rounds then selected S26's one-model self-composition
probe, with independent design review and locked controls for mask-count scaling.
Seven forwards / 112 rows over four reference constructs completed in 10.1455s;
repeat probability drift was zero. Root read all 16 decoded pairs. These are
reference recoveries, not biological quality, held-out generalization or acquisition.
Receipts: ledger `autonomous_continuation_design_20260913` (fresh CLI sessions
01a09d0d-bee5-7ee2-b682-f5a9a17c59b8 and 01a09d11-6b92-7fe3-96ee-c260c44cf46c),
`encoder_continuation_v1_intent` and `encoder_continuation_v1_result`.

### Later strategy: procedure reuse and predicting revision consequences

Two-round dialogue specified S2.2's reusable acquisition procedure: its recipe,
evidence permissions and budget rule persist across donors, while adapters and
receiver weights may learn. New hand-engineered recipes are method revisions;
fresh inputs and new operation combinations distinguish capability from cached
annotations. S12's tied-head calculation saves no unique weights when the input
embedding remains; contextual encoding can avoid generation without becoming
small. This is conditional bookkeeping, not a proprietary or runtime claim.

S25 incorporates lifelong editing rather than excluding text exports: MEMOIR's
learned correction and mask routing, RippleEdits' consequence tests, and
StableEdit's qualified stabilization evidence. None is replicated. Dependency
rules need explicit semantics/correction policies; types alone do not establish
entailment, and orthogonal updates alone do not preserve reads. Answer import
and acquisition of useful consequences are different legitimate branches.

Two fresh real CLI design rounds then sharpened S24's hypothetical 12-to-10
carton correction: the 30-item answer stays fixed, the 36-item answer changes.
Possible dependency, correction applicability and actual answer change differ.
One trusted applicability distinction resolves the stipulated two-world case;
a typed field suffices. A later answer used to infer scope is acquisition evidence,
not an unqueried consequence test. This instantiates S1/S23, not a new theorem.
Caller dependency routing supplies integration behavior, not a discovered learned
law. The dialogue rejected another generic impossibility or renamed program slice.

Geiger2021's existing causal-abstraction bridge separates a symbolic test target
from consequences computed by the intervened neural model. Its MQNLI models
receive task and phrase-relation supervision; the source is not evidence of a
new method or pretrained cumulative graft. Root and independent reader verified

this boundary; no exhaustive pair/clique procedure was imported.
Receipts: ledger events `acquisition_reuse_revision_precedents_20260913`, `revision_consequence_design_dialogue_20260913` (fresh sessions 01a09ced-ed65-7ab0-809e-c9c8353d18f7 and 01a09cf2-0c79-77b2-8c58-03082c4518e0), and `causal_abstraction_strategy_bridge_20260913`. Both CLI sessions kept boards read-only; design dialogue does not replace the periodic approach audit.

### After 21:42 UTC: task eligibility, worked episode and attribution

The task-first PFN1 candidate closed before its 90-minute limit. Test row 125 and training rows 375/440/910/936 share the exact question/disease answer despite verified sequence edits. Exact-question lookup suffices for this endpoint; there is no whole-benchmark score or claim that the trained model ignores DNA. The final formatter omits nucleotide changes, so these pairs do not instantiate the earlier contradictory-text swap concern. Shared labels make the proposed functional contrast unmeasurable. The loader combines 146 test and 144 validation rows, explaining 290 without proving historical selection protocol. No usable original receiver was verified on scoped official surfaces. Missing resources: independent answer-changing effect labels, receiver role competence and its artifact. S8 and ledger retain revisions, row locators, hashes and independent checks; no replacement system was trained to manufacture eligibility.

S24's actual released table illustration assigns text/locations to OCR, boxes to the structure donor, binding to geometric postprocessing, and late queries to an explicit executor. Two-round dialogue and pinned source inspection rejected crediting fixed binding rules to the donor or weakening the structured comparator to a hard table. No OCR/pipeline/training ran. The conditional route to an answer is explicit, but superiority over grouping or direct source extraction is unmeasured. Token identity, crop coordinates and header conventions can require translation/revalidation. Coordinate repair is caller work, not a latent hole; a later two-round dialogue declined crop replacement because wrapper independence would supply its laws. This is an on-paper episode, not a document product.

The full S3 stitching source replaced its abstract-only placeholder: class-centre noise is informative and supervised adapters can learn correspondence. Useful acquisition does not establish preservation of donor computation; learning is valid when attributed. README's historical 6.3× contrast was qualified without changing its value; the experiment log preserves the historical interpretation.
Receipts: `table_growth_episode_20260913` and `graft_interpretation_revision_contract_20260913` in the ledger.

### 21:42 UTC: first periodic approach review

Fresh CLI 01a09cb3-77b6-7840-a52e-a5b0099e7822 reviewed consolidated HEAD 0a93fb7 and retained evidence, with audit-board synthesis; root relayed e1027. Continue the direction, but availability-led diagnostics are not working as route selection. Adopt one specialist-encoder/KEGG eligibility block of at most 90 minutes: trace an actual answer, roles, coupling, ports, later growth and an old use to preserve; return a populated contract or exact missing resource, not another diagnostic.

Independent two-round dialogue also corrected two restrictive assumptions: role competence need not mean standalone end-task superiority, and frozen-receiver interchange is narrower than acquisition. A failed average does not rule out richer useful distinctions. No architectural hole or acquisition was established.

### Before 21:42 UTC: three bounded probes and their consequences

| Probe | Preserved outcome and qualification | Corrected evidence / review |
|---|---|---|
| S6, retained exports | Legacy plan exports nonfinite or overwhelmingly zero; ineligible for proposed plan-transfer analysis, not a test of model capability | [result](experiments/results/acquisition_cache_integrity_v1/result.json); restored audit e1011–e1012 |
| S21, conditional port, 20:59 checkpoint | Four fixed rectangles below all registered tolerances; eight CPU forwards, 60.27 seconds, no fitting. Post-hoc additive preferences also fit primary tolerance: no useful updating mechanism or global law | [result](experiments/results/conditional_port_v1/result.json); fresh CLI audit e1021, exact arithmetic and scope in S21 |
| S22, cached output screen | Locked two-column equal-rank average loses to retrospectively better donor on four assays / 8,610 matched finite variants; 23.86 seconds including retrieval, no model calls. No absence-of-complementarity or graft-feasibility conclusion | [result](experiments/results/cached_donor_screen_v1/result.json); fresh CLI audit e1022 required integer rank sums for exact ties. Offline correction independently checked with SciPy, maximum correlation change 0.00001343, direction unchanged; original source/result history and byte-preserving Git attributes retained |

Two design dialogues selected S21 after video resources lacked matched observation access and a fixed receiver; the diagnostic closed without searching for dramatic cases. S23's independent analytical dialogue separated pairwise from joint compatibility and compatible completion from identified answers. Joint use needs coupling evidence or declared assumptions/uncertainty, not necessarily one global world model. The three probes remain closed, with no automatic panel expansion.

At the 20:45 checkpoint, S16–S20 separated ordinal messages, calibrated quantities, information novelty and usable computation. Pinned onboarding source lacked an initial/replacement-content control and compared pooled with single receivers; its speed headline cannot establish donor contribution, but donor nonuse is not proved. Three JSON summaries lacked frozen example-level messages/labels for an alternative-reader replay. Encoder use also needs an inference schedule and cross-donor calibration. No external model or training script was executed.

Earlier S11–S15 distinguished observability/writeability, exports, conditional value, interchange and extension. Scene/assignment runs were declined; a fixed hub can preserve donor-specific information, so alignment is not itself a bottleneck proof. S10.3's approximate export count includes recipient side information and is not a model-size lower bound. S8 initially flagged that a sequence-only swap may contradict variant-identifying text; the later PFN1 formatter inspection above resolves that concern for its specific example.

### Opening and consolidation continuity

Initial review placed access, identifiability and complementary usefulness before architecture; access ambiguity and conservative extension framed the first questions. Independent sweeps consolidated current routing without deleting historical sections. Scoped methodological residue went to the closed capability-translation

sibling (commits 57f8623 and 41aaab7) and the LSR row/lesson in the unversioned portfolio index; no other portfolio claims or sibling closure were reassessed.

Reverse-chronological running log. Newest first. Each entry: what was done, what was learned, what's next. Canonical state lives in STATE.md.

### README propagation and theory status index (2026-09-06)

README still claimed "well-defined operators on a probability simplex ... the coordinate system native to the model's computation" (K_A framework recorded DEAD on 2026-09-04) and "operator algebra finer than semantic role". Propagated the audited wording: no stable operator algebra (congruence failure 2.6-13x; logit-bias rival); surface-specific responses; the filler reading (equal-length blocks unequal); the neutral-vs-reassignment reading with its reduced-readout, unmatched-position limits; a "current direction" paragraph with conditional mathematical results and the open empirical question; repository structure updated to the six runners. Added a status index at the top of the theory document. Codex quota at 92% (resets 2026-09-10): no audits possible; no new theory claims will be added until then.

---

### Evidence gate on block 3: REVISE; reference scale confounded; rotation ruling (2026-09-06)

Arithmetic reproduced exactly (72 rows; 576 concatenations token-matched; 480 laws valid). Length-only rival conditionally rejected at the 11-bin W_0 channel (24/24/23; survives the largest admissible guard). My reference scale was confounded: each filler PAIR changes both the input pair's filler_A and the successor filler_M, so the "between-filler spread" mixes input-pair and successor variation; the fixed-input successor range B(i,j) over j is what is needed and its off-diagonal endpoints are absent. Withdrawn: "H not distinguishable from an arbitrary comment", "content-specific H disfavored". Order 2 compares A (neither H nor N). No affine rival test possible (no initial d_i). Decision amended: fixed-input, response-independent successor fillers, prospectively specified.

Ruling: rotation blocks 1-3 produced useful decisions (corrected architectural claims; strong-assert prioritized; the missing fixed-input filler control exposed) but no artifact; stop zero-call rotation pending compute approval. Named acquisition: position-matched full-law eligibility-first panel on repaired strong-assert pairs (five blocks; floor measured; five robust W_H-close pairs; N/H successors; three fixed-input successor fillers). Devansh's standing rule is never idle and rotate: so the next block is analytical preparation that does not reopen closed lines.

---

### Block 3 reading: fillers differ from each other more than H differs from a filler (2026-09-06)

Zero model calls. Multifiller table (Gate 2 v2 repair data): surfaces and fillers token-matched by construction (5/5 and 7/7). Length-only rival

(|b_H - b_F| <= 0.002 on identical input pairs) violated in >= 23/24 roots for all three fillers and both orders; sign of the deviation filler-dependent. Reference scale: between-filler spread median 0.098 (order 1), 0.084 (order 2), versus content-vs-filler deviation medians 0.017-0.027 and 0.025-0.069; content exceeds the filler spread in 0/0/1 roots (order 1) and 0/2/6 (order 2). Reading: any 7-token comment perturbs pair discrepancies about as much as the "reassignment" comment; the content-specific H hypothesis is disfavored; the deferred panel needs >= 3 fillers and the between-filler spread as reference. Limits: initial closeness unknown, 11-bin, floor assumed. Evidence gate next.

---

### Evidence gate on Q4: REVISE; decision amended; next block = multifiller (2026-09-06)

Codex recovered the deleted runner from git (c2465ba^) to confirm arm semantics (_c0/_c1 = surface -> composer -> query; _c0r/_c1r reversed), reproduced all 72 rows with zero discrepancy, and found: (i) "full-law witnesses" overstated: an 11-bin split proves post-H full-law separation, not a counterexample to full-law preservation (initial full-law closeness unknown); (ii) the guard is assumed (no replay data in this table); (iii) the two surfaces of each pair differ in token count (4/5, 4/6, 4/7), so composer/query positions are unmatched: under the locked interface the verdict is INCONCLUSIVE; (iv) my positive-verdict branch was too weak in general (must bound every potentially close pair) though the counts stand; (v) median bug (upper-middle), fixed. Decision amended: strong-assert as candidate family for a NEW position-matched full-law eligibility panel; do not replace the deferred panel (CRC-0 lacked W_H-close pairs; Q4 supplies W_0-close pairs; only three W_H-close pairs exist here over two blocks). Q4 is decision-relevant. Next: multifiller reading, TV(AM, F_AM) vs TV(AF_M, F_AF_M) on the same roots, beyond 0.002, after verifying token matching; if non-actionable, stop rotation pending compute approval.

---

### Q4 reading: N preserves, H witnesses, on the archived congruence panel (2026-09-06)

Zero model calls. The svb_qwen3_congruence table (24 cells x 3 presentation pairs x composers N/H, 11-bin laws) contains exactly the CR-15.10 quantities D0, DN, DH for forward order. At tau = 0.01: strong_assert 24/24 close, N preserves on all (max 0.0064), H witnesses 23/24 (max 0.116); moderate_assert 8/24 close, N preserves (max 0.00999, borderline), H witnesses 6/8; misleading 1 close pair, split under both. Reduced channel: H witnesses are valid full-law witnesses; N's preservation is reduced-channel only. Decision candidate: the deferred panel's root family should be assert-type presentation pairs (>= 24 close pairs vs CRC-0's zero), N as the plausible preserved action, H as the witnessing action. Evidence gate next (one Codex call).

---

### Audit #42 on CR-16: RESTATEMENT; rotate to Q4 (2026-09-06)

Audit #42: RESTATEMENT; CR-16 requires corrections. Fixed-token causal site invariance and, with consecutive positions, the appended-token offset identity are retained. The exact two-route decomposition, content-independent prefix re-weighting, filler-effect subtraction and identification with CEG-1 RELAY-CUT are withdrawn. CR-15.10.6 already requires matched positions, valid tokenization boundaries and the registered H-versus-F rival. Close Q1 and rotate to one bounded Q4 reading of existing audited response tables under their original interface and claim limits, with no runs or new acquisition.

Why the two-route decomposition failed: tokenization can change prefix IDs; 'exactly k' needs consecutive position IDs; the new keys' softmax contribution is content-dependent; the final query state is new and content-dependent through earlier layers; residual/MLP paths at the read position contribute even with zero attention output projections; new-site information changes the later query which changes its weighting of old sites, so the routes overlap causally. Historical RELAY-CUT blocks live_start.. -> dead_span attention, not query -> appended block. Program: continue; 'not working as a route to a real-model artifact'; Q4 is one bounded evidence-to-decision map, then a decision or close.

---

### Question rotation block 1: CR-16 architectural restrictions (2026-09-06)

Devansh: never stop; rotate questions; spare the machine. Proposed five compute-free questions; Codex ranked Q1 (forced identifications of the transformer world) first with a strict gate: it counts only if it yields a nontrivial consequence for W_0/W_H/W_2, else rotate to Q4 (existing evidence). Codex corrections to my five statements: (1) rotary symmetry = origin relabeling of all position IDs, not prefix-length changes; cite RoFormer; (2) causality exact but site-local; appending changes the read position; (3) RMSNorm eps > 0 is NOT scale-invariant; pre-norm residual breaks ray invariance; a pure pre-LayerNorm stack under the stated final-reader conditions has a whole-stack shift symmetry; my ray quotient withdrawn; (4) multiset identification withdrawn (I had already withdrawn it); (5) parity is in TC0, Hahn's rate is for non-causal attention; scope separately.

Drafted CR-16 with the one consequence I can prove from 16.1 + 16.2: the appended-block offset effect. Any appended block of length k increases the final query's offset to EVERY frozen prefix site by exactly k, content-free; so the B-question differs from the immediate read through exactly two routes: (a) re-weighting of frozen sites (present for fillers too) and (b) the new sites' prefix-conditioned representations. Consequences: the length-only filler is mandatory, not a straw man; W_H-splits of W_0-close pairs can be offset effects; RELAY-CUT geometry is derived; question families should be stratified by appended length. One audit next.

---

### Audit #41 on CR-15.10.7: REVISE; analytical cycle stops (2026-09-05)

Fresh audit of the seven draft items plus my self-critique. Retained: (2) finite-panel enclosures, (5) refinement identity, corrected moduli (1) and conditional routes (4). Withdrawn or replaced: the obstruction theorem

(a depth-one transcript can force omega(0)=1 in EVERY consistent world, so the "zero-modulus completion" claim was false; replaced by a finite response-transcript obstruction that asserts only the unit-modulus completion); the cyclic parity claim (two consecutive cosines determine the phase for every m >= 3 via sin(j a) = (cos(j a)cos a - cos((j+1)a))/sin a; gain bounded by 1 + 2|cos a| <= 3, not unbounded); the coordinate-replacement row (needs a product-max response metric; counterexample given); (4b) needs FULL-PROFILE Lipschitz control, not immediate readers; the saturation impossibility (lambda >= e^G/L_g on same-sided domains survives as a conditioning statement; an arbitrarily saturated reader can still give L kappa lambda < e/4 < 1); the rank proposition (local necessary condition K >= d survives; the global s_min bound is false, with a circle counterexample; Jacobian rank is not PSR dimension; W_H is two FULL-LAW questions, not two scalars, so no rank deficiency follows; the rung-1 reader is rank one on an open 16-dim domain, which rules out carrier-metric inverse observability there but not behavioral guarantees). Also: the saved certificate result stores mean probabilities, not per-cell logits, so |g| ~ 18 was not established; "order-one carrier separation" is compatible, not indicated.

My self-critique was only partly resolved (4 of 6), and one of my "fixes" (parity) was itself wrong. Lesson recorded in memory: hour-by-hour solo derivations without review accumulate errors; audit before extending.

Ruling: one correction-and-consolidation pass (this), then STOP the analytical cycle and wait for approval of an empirical step that can change a program decision. "This is not working as a route to a real-model artifact." Program remains open.

---

### Inverse observability is a rank condition (2026-09-05, heartbeat addendum)

Continuing (6): premise (4b) needs the question family's response map to be injective on the invariant set, hence at least d questions for a d-dimensional carrier, with a well-conditioned question Jacobian; lambda <= 1 / inf s_min(J_P), and saturation multiplies s_min by e^{-G}. The relevant d is the behaviorally effective dimension (rank of carrier -> all-future responses), i.e. the PSR dimension; a family attaining it is a core test set (PSR/OOM prior art, used not claimed). Consequences: the deferred W_H panel (K = 2) can never give an upper bound on omega beyond the panel (rank-deficient by construction; witnesses and panel moduli only); the rung-1 reader was rank ONE on a 16-dim carrier, so no immediate-read family could have supplied inverse observability there, a structural reason visible before any run.

---

### Saturation destroys inverse observability (2026-09-05, heartbeat addendum)

Item 6 of my self-critique, derived: for a sigmoid/softmax channel, on the

region |g| >= G the response compresses carrier differences by e^{-G}, so the inverse-observability constant lambda >= e^G / L_g and premise (4b) cannot hold from saturated immediate reads. Applied analytically to the recorded certificate run: correct-slot probabilities within 1e-8 of 1 mean |g| ~ 18, so the 1.4e-8 erasure TV is compatible with ORDER-ONE carrier separation between obsolete-write counterfactuals; the panel erasure may be entirely reader-side. Pre-registered seconds-long check on the saved weights written down but NOT run (evidence gate: no follow-up on that cell). Design consequence for the deferred real-model panel: choose continuations by response entropy so that some questions are unsaturated.

---

### CR-15.10.7 draft: the analytical deliverables, written solo (2026-09-05)

No Codex (quota). Delivered in theory/ as DRAFT: (1) moduli for seven world/family rows; the cyclic counter shows both failure modes in one world (consistency failure under immediate reads; exact closure with amplification once one extra question is added). (2) Finite-panel bounding proposition with proof; the panel modulus lower-bounds the domain modulus and never upper-bounds it. (3) Obstruction theorem: any finite transcript is consistent with worlds having omega(0) = 0 and omega(0) = 1 (countdown branch attached beyond the transcript horizon). (4) Three premises for an upper bound: finite orbit (exact enumeration at depth N - |Q_0|); contraction + reader Lipschitz + INVERSE OBSERVABILITY (rho <= lambda d_{W*}) giving omega <= L kappa lambda t, which reproduces the CR-15.9 world's t/2 exactly and names the half the certificate lane lacked; closed invariant relations (bounds only pairs in a common realization set). Proposition: a denizen certifies lower bounds, panel moduli, and refutations; never an upper bound. (5) Refinement modulus rho_h(t) = max(sup_{eligible} d_{W_h}, max_a omega_a^{W_h}(t)) (corrected per audit #41). Review pending (fresh audit when quota allows). Nothing here is a real-model finding.

---

### Direction locked: CR-15.10.6, analytical cycle on finite-question certification (2026-09-05)

Round 3 (locking). Interface AMENDED (actual token positions and typed context, not character counts; W_H successors need execution-order tuples (a,) and (a,H); P2's `func` vs `f` malformation; dense laws must be saved). Guarantee AMENDED (tau = 0.01 locked; five pairs = coverage over five task blocks, not statistics; CRC-0's 7e-7 was a 4-sentinel cached-vs-full mean, not a replay floor). Prediction REPLACED (P and R are not exclusive; the doubling world already shows exact sufficiency with amplification; safety prediction P on reserved endpoints + a prospectively reserved disagreement set). Rival rule REPLACED (my CV rule is unsound: b/d = g + c/d; use interval-aware affine infeasibility with eps_R = 0.002, and a separate length-only rival with a position-matched filler). Evidence route REPLACED:

analytical first; the historical panel has ZERO eligible W_H-close same-variable pairs, so the proposed positive gate could not succeed on it; 1.7B panel deferred and needs explicit approval.

Codex independently derived the same four moduli as my worked-examples note (countdown 1; doubling min{1,2t}; CR-15.5 theta t; CR-15.9 half min{t, delta}); my note adds the cyclic counter's two-mode case and the refinement modulus rho_h(t). The substantive analytical gap named: turning finitely many questions into an UPPER bound on omega needs an observability premise in the other direction (small d_W => small carrier separation), which neither CR-15.2 nor CR-15.3 supplies.

Codex weekly quota at 75%; no further Codex calls today. Next: deliver the four analytical items of CR-15.10.6 solo as a DRAFT in theory/, for review when quota allows.

---

### Direction dialogue round 2: propagation inequality kept, "iff" replaced by a modulus (2026-09-05)

Codex round 2 on my rule attempt. Kept: d_W(T_a x, T_a y) = d_{aW}(x,y) exactly; the propagation inequality with corrected display. Replaced: my "propagates iff closed" with the modulus omega_a(t); exact profile closure preserves exact equality but need not preserve positive tolerances (T(x) = min(1,2x) doubles small discrepancies); sufficient fixed-tolerance condition L_a tau + 2 delta_a <= tau. Correspondence with CR-15.2 is exact at eta = 0 on an invariant set with all immediate channels in W, with NO L <= 1 requirement; not exact in general (abstract state may remember distinctions absent from W). My countdown example had a factor-of-two error (radius vs diameter). Angluin: I had misnamed consistency as closedness. No mathematical novelty; value must come from real-model predictions.

Real-model: my "immediate-read family closed under N, not under H" reading is NOT licensed; licensed sentence is continuation-dependent amplification at 11-bin resolution. CRC-0 never saved its 36 x 13 laws (runner computes, saves summaries; config description mismatches), so the enlarged-family test needs a rerun; but two recorded witnesses already reject preservation of the 0.01 tolerance under H (d4_y_3, d4_y_5 presentation pairs).

Adopted as CR-15.10. Direction: interface-relative approximate interchangeability with omega_a(tau) as organizing quantity. Round 3 must settle interface, guarantee, one consequential prediction, cheapest rival (lexical/position readout sensitivity), evidence route. Codex weekly quota being rationed.

---

### Re-contextualization round 1: register-free theorem adopted; direction reset (2026-09-05)

Codex counter to my re-contextualization note. Adopted: CR-15.9, the register-free CR-15.8 (least congruence generated by eps-accurate word

equations; endpoint loop-erasure; (N-1) eps; no factor two). Corrected: I had promoted finite N into an organizing necessity; it is one sufficient premise among three (counting, contraction, closed invariant relations), with an explicit infinite-orbit contracting counterexample. "Local" means a short equation whose eps bounds all futures, not a short horizon.

Trap ruling: the von Neumann diagnosis is substantially right (engineered addresses/values/readers certified as discovery), but coordinate-free wording is not an escape by itself; a human-chosen interface is not native because it avoids coordinates. Four explanations of the certificate result remain live (reader hides history; expansion off the useful region; expanding directions irrelevant; short-horizon shortcut).

Direction: option 4 + new option 5 (interface-relative erasure and preservation): produce one explicit rule about when an erased distinction stays irrelevant under subsequent actions, anchored to CR-9's real-model pairs, with a counterexample and an intervention consequence. Discrete carrier deferred (finiteness is designed in; BFS counts concrete not behavioral states; quantization changes the certified system). No run.

Codex's mandatory answer: continue the program; the selective-reset line is "not working yet" as a route to the central real-model artifact. Honest accounting today: zero new real-model-building cycles; one 130 s tiny-cell retrain; two theory blocks adopted; two audits + one evidence gate.

---

### Certificate check: INCONCLUSIVE, premise fails on the fixed cube (2026-09-05)

Design gate GO (round 4) with a ten-step protocol; my Claim 1 (CR-15.8 vacuous on continuous carriers) refuted in its strong form by a dense-orbit example with packing number 1; my Claim 3 corrected: a bare positive per-step foreign-write drift bound does not prove arbitrary-history preservation. Contraction with a sufficient radius is one remedy; direct invariant-tube containment is another and does not require foreign-write contraction.

Implemented the certificate in run_commit_seal.py (mode single_cell_certificate; mpmath.iv 128-bit outward arithmetic; PyTorch GRUCell gate convention; SiLU reader gradient enclosed). Smoke test on a one-epoch cell exercised the inconclusive path only; it did not validate the general PASS path. The evidence gate later identified endpoint-comparison, reader-offset, fixed-point-enclosure, and serialization defects (fixed after the run; not rerun).

Real run: seed 11 sealed, 200 epochs, 130 s. acc 1.000, erasure 1.4e-8. Invariance PASS. kappa_hat over the full cube = 5.88 -> INCONCLUSIVE. Witness search (refutation direction only, same domain/norm): confirmed expansion pairs for both values (1.11, 1.17). So this is a genuine premise failure on [-1,1]^16 in the inf-norm, not interval conservatism. Sampled Jacobian inf-norm at fixed points: 0.987 (v=0), 0.539 (v=1).

Evidence gate (REVISE): the finite-panel result coexists with reported

interval-confirmed expansion on the fixed cube. Candidate cancellation is compatible with these observations but was not demonstrated. Expansion does not eliminate conservatism in the reported 5.88 estimate. A box enclosing short histories, even with a margin, is not an invariant-domain certificate. This attempt closes without another run; the wider behavioral-realization question remains open. Apparatus ratio in this lane 5.71:1 -> lane closed.

---

### Audit #40 on CR-15.8: ADOPT core, REVISE guards and attribution (2026-09-05)

All proofs verified (loop cutting, right-to-left count k(n-k)+C(k,2), endpoint chain with no factor two, fidelity corollary, both lower-bound constructions, 3^k vs 2^k, packing theorem, irrational floor strengthened to exact attainment D = N tau, ultrametric remark). Corrections applied: parameter guards (N>=2, eps>0 for the sharpness examples; zero cases separate), the binary example keeps its live bit exact (nuisance error only), prior art (quantitative algebra: Mardare-Panangaden-Plotkin; metric rewriting: Gavazzo-Di Florio; Moore; Girard-Pappas), status line, STATE summary and next obligation.

Program ruling: continue; the next step is one useful behavioral error bound on one fixed learned endogenous interface. A rigorous interval-arithmetic contraction certificate on one trained ~17K-param GRU cell is a legitimate "derivation needs a concrete check", becoming a campaign only if it searches seeds/models/norms. Conditions: actual learned transition and native reader, verified invariant domain and initialization coverage, derivative-to-distance passage, reader calibration, every registered action; proving kappa < 1 alone is insufficient; a failed certificate is inconclusive, not evidence against overwrite. Pointer: Bonassi-Farina-Scattolini GRU stability conditions (Lemma 1, Thm 2) to check first.

---

### CR-15.8: state budgets bound accumulated write-law error (2026-09-05)

Round 3 on audit #39's question. My attempt: loop-cut in the joint system Q x P, then rewrite; I first counted the rewrites as quadratic, then claimed linear via "each write crossed at most once per register". Codex verified the loop-cutting lemma, refuted the unqualified crossing claim (word r r s r: eliminating the second r first makes s cross two dead writes), repaired it with a right-to-left procedure (rho <= k n), and then found the stronger theorem: shorten the ENDPOINT CHAIN of the rewrite proof, not the execution history. All chain states lie in K_alpha, so cutting repeated vertices leaves <= |K_alpha| - 1 edges of size eps: diam K_alpha <= min{1, (N-1) eps}. No |R| or |P| factor, no factor 2. Lower bound Omega(min{1, N eps}) from the cyclic phase example with faithful margin 1; exact (N-1) eps attained by two singleton registers on a line. Tolerance version via packing number. Three suppliers of history-uniformity: finite exact state, contraction, closed invariant relations.

My secondary lean was corrected on both counts: c_tau = 0 is not a characterization of overwrite, and append-only carriers can have exact last-write readers. Neither survives; recorded so they are not retried.

Codex round 3 first attempt hung 90+ min on bb_synthesis of the mission board (too large); killed and relaunched with synthesis skipped. Memory note written. Codex weekly quota at 66% used.

---

### Audit #39 on CR-15: REVISE, corrections propagated (2026-09-05)

Fresh unprimed audit. Core retained (15.0, 15.2, 15.3, 15.5, 15.7 ADOPT). Revised: 15.1 (untouched-value example typing; the factorization is a set-with-action isomorphism, not a metric product; it is a very-well-behaved lens, Foster), 15.4 (zero-radius paragraph; calibration at mixed centers; "selective forgetting" sentence softened), 15.6 (paired-pool lemma now has explicit hypotheses; state-tracking prior art added: Merrill-Sabharwal, Liu et al., Mamba, Illusion of State). Also fixed CR-4 proof opening, CR-5 cardinality caveat, CR-9 exact-equivalence overreading, CR-12 "TESTED" -> "REQUIRED EVIDENCE".

Withdrawn from every surface: "distance from claim 0" and "pretrained transformers lack an endogenous overwrite boundary" (CEG-1 failed its competence preflight; retained raw history is not retained behavioral distinction). STATE, theory CR-10/CR-14, EXPERIMENTS CEG-1 edited.

Program ruling: continue selective behavioral reset; generic contraction certification is not the highest-leverage next step. Next question: sharp state-budget/error tradeoff turning eps-accurate local write laws into a history-uniform store abstraction with no product coordinates or tubes. My attempt (loop-cutting in Q x P then rewriting) gives C = O((N|P|)^2), lower bound Omega(N) from the cyclic counter; round 3 asks for the sharp exponent.

---

### CR-15 adopted: selective behavioral reset, representation and certificates (2026-09-05)

Compute-constrained analytic mode began today (directive: derivations and proofs, tiny models only, recurring entropy sweeps). Two-round dialogue.

Round 1 lean (mine): make CEG-1/CRC-1 a theorem by bounding absorption defect below by attention mass on dead tokens; gated overwrite needs a saturated gate. Both refuted with explicit constructions: values and projections can annihilate dead mass, and a scalar GRU with gates at 1/2 overwrites exactly on {-a,a} by candidate cancellation (verified numerically). Adopted instead: common-kernel representation Q_sat = B x S, and the invariant-set 2-eta theorem.

Counter-round (mine): the invariant-set theorem has no supplier; contraction supplies it (CR-15.3); fibered contraction is the approximate shadow of B x S (CR-15.4); conjecture that a shared gate cannot do two registers.

Round 2 verdicts: CR-15.3 repaired (the interval [-a,a] is NOT invariant for the scalar construction despite |U'| <= 0.11, so a contraction certificate needs a verified invariant domain and initialization coverage); CR-15.4 false as stated (consistent fixed points do not give commutation; defect kappa(u-y)(x-v)), replaced by a selective-tube certificate; keyed-gate conjecture false (constant gate, address in the candidate). Partial writes reconcile the two CR-11 bounds. Corollary: selective memory requires selective forgetting.

What this changes: the rung-1 experiment's claim-bearing object is now a certificate (invariant domain + contraction + reader margin), not a paired-erasure table. Erasure tables can pass for reasons that do not survive history length (cyclic-counter counterexample).

Repo entropy sweep also completed today: 98 scripts, 47 configs, 134 result dumps removed (manifest kept); STATE 3477->192 lines, NOTEBOOK 14614->845, closed theory under theory/closed/, handoffs merged.

---

### CR-14 revised to commit-seal carrier (2026-09-04)

Codex design gate corrected the original CR-14 hard-register experimental design as EAC tautological: hard-wired overwrite guarantees |Q_H|=16 by construction, so testing whether it erases is circular. WB-1 validates the math (|Q_H| matches $\prod|V_r| = 4^2 = 16$, the store cardinality for initialized registers) but is architecturally tautological — a single-seed diagnostic, not L1-L4 validation (Codex: learned write heads unused, overwrite arm retains history-bearing GRU path, arms have unequal parameters).

Revised CR-14 uses commit-seal carrier: hard SEAL (information bottleneck erasing pre-commit activations) + LEARNED update U(m, proposal) → m+. The model CAN fail (encode both old/new values, entangle addresses, ignore carrier). The learned update is the falsifiable object.

Also corrected: L1 renamed "absorption" (not "idempotence"). Quotient bound: $\prod|V_r|$ for initialized registers, $\prod(|V_r|+1)$ only when registers have a distinct unwritten state.

Positive-control staircase: rung 1 = 1 address, 2 values, 2 commits, counterfactual pairs, self-transplant + no-seal ablation + value-proposal shuffle (not scrambled-address — impossible with 1 address).

Codex WB-2 design gate (compositional): strongest candidate is chained Z4 operations (A(x,y)=(x+y mod 4,y), B(x,y)=(x,x+y mod 4)) but it should run at rung 3, after rungs 1 and 2 pass. Z4 is imported algebra (scaffolding), not native latent math — the native candidate is the behaviorally established congruence and induced transformation semigroup of the learned carrier.

---

### WB-1 complete: F4 — task too simple, overwrite hits exact bound (2026-09-04)

First constructed artifact. Two GRU models (~25K params, CPU), 2 registers × 4

values, 5-step sequences. Overwrite model: |Q_H|=16 EXACTLY (theoretical bound), store alignment 1.000, 100% generalization to length 15. Append-only model: |Q_H|=20, alignment 0.750, 99.9% generalization. Both compress ~2000:1.

F4 fires: the quotient ratio (1.25x) doesn't clear the 1.5x threshold. Simple fact-tracking is too easy — a GRU+attention learns last-write extraction without needing the overwrite boundary.

**Signal:** The 25% history leakage in append-only IS the architectural difference showing through. 4 of 16 store states have history-dependent behavior in the append-only model, vs zero in the overwrite model. The difference exists but doesn't bite on simple tasks.

**Next:** WB-2 with compositional cross-register operations. The task must require reasoning ACROSS registers, not just individual register reads.

---

### Pivot to construction: Selective Write-Boundary program (2026-09-04)

Codex direction dialogue: skip CEG-1R, close Qwen path-dependence line, pivot to constructing a latent substrate with an explicit write boundary.

**Decision logic:** CEG-1R's outcomes both lead to the same next step (construction), so running it is measurement entropy. Measurement-to-artifact ratio was infinite (506:0), governance requires halt above 5:1. CEG-1R is not literally the R^n trap but remains an outside-in measurement tunnel — it characterizes what a surgeon can cut, not a move available to a denizen.

**Critical pushback adopted:** The write boundary alone is NOT the artifact (repeats EAC tautology). It is a declared substrate axiom. The scientific question is whether a learned denizen can USE it for portable, compositional predictive states.

**Theory (CR-10 through CR-14):**

- Laws: overwrite idempotence (L1), cross-register commutativity (L2), preservation of unrelated distinctions (L3), write fidelity (L4)
- Theorem: every write history has a unique last-write normal form; predictive quotient bounded by store cardinality ∏(|V_r|+1), not history length
- Five pre-declared falsifiers (F1-F5), each testable in one round
- Primary gate (F1): overwrite model must produce a smaller quotient than matched append-only ablation

**Narrative:** "Give a model an internal act that genuinely means 'replace this fact,' then test whether compositional reasoning becomes possible because dead history is truly dead."

**Next:** Codex design gate on CR-14 experimental design, then implement the smallest model that can be wrong (2 registers × 4 values, 5-step sequences).

---

### CEG-1 Evidence Gate: REVISE — bounded context dependence, not relay (2026-09-04)

Codex Evidence Gate (audit #38) returned REVISE / formal NO_INTERFACE. The RELAY headline does not pass. Corrections adopted verbatim.

**Key corrections:**

1. RELAY-CUT Δ=0 is tautological — downstream positions see only pair-identical tokens. Not an empirical finding.
2. Under QUERY-CUT, register-specific dead-value effect disappears: target and orthogonal channels show equal excess (0.062 vs 0.061). Residual is broadcast context sensitivity, not semantic relay.
3. "52/48 pathway split" is invalid — used arm-specific channel maxima.
4. Competence preflight failed (83.6% < 95%); binding design required NO_INTERFACE.
5. Measurement-to-artifact ratio: infinite (506:0).

**What survives:** Paired excess (QUERY-CUT − DUMMY-CUT) = 0.101, bootstrap CI [0.050, 0.152], p=0.001 at block level. A hard attention reset at first live write recovers 100% accuracy — the append-only carrier lacks an endogenous overwrite boundary. One canonical restatement is not an ε-synchronizer.

**Next:** CEG-1R (terminal Qwen localization test) or close Qwen path entirely.

---

### CEG-1 RESULT: RELAY (pre-audit) — dead info relayed through attention (2026-09-04)

914 forwards, 259s. Custom 4D attention masks, eager attention, full forward passes. Fixture perfect (TV=0.00), mask effectiveness confirmed (TV=0.856). Original RELAY verdict superseded by Evidence Gate above.

---

### CEG-1 design: Causal Erasure Graph v1 (2026-09-04)

**Direction pivot (Codex strategic review):** CRC closed on Qwen3-1.7B-Base. Next instrument: position-controlled causal-erasure via attention mask interventions. Binding question: when an assignment becomes semantically dead, does its influence survive through direct KV access, relay into later states, or because no legal continuation synchronizes the model?

**Design:** 16 fixed-slot histories (4 dead combos × 4 live stores) × 4 rendering templates (2 calibration, 2 held-out). 6 intervention arms: OPEN, QUERY-CUT, RELAY-CUT, DUMMY-CUT (on dummy-register histories), LIVE-CUT (positive control), SYNCHRONIZER (append live-store restatement). Custom 4D attention masks with eager attention, complete forward passes (no KV cache). Fixture validation: OPEN mask must match standard inference within TV 1e-5. ~900 CPU forwards.

**Predeclared interpretations:**

- QUERY-CUT collapses → dead info directly reread from old KV cells
- Only RELAY-CUT collapses → dead info relayed into later states
- SYNCHRONIZER collapses → denizen-executable reset word exists (→ reuse CRC)
- Neither works, LIVE-CUT does → distributed/redundant (stop Qwen line)

**Codex adversarial corrections adopted for STATE.md:** "Dead histories haunt" replaced with licensed sentence; competence-failure overclaim corrected; relation rates marked as confounded.

---

### CRC-1 result: INVALID / bounded negative (2026-09-04)

CRC-1 complete. 1508 forwards, 357s. Two-register overwrite semigroup on Qwen3-1.7B-Base. Task-aligned {0,1} observer — the coarsest possible observer that captures task semantics.

**Result:** INVALID (competence 87.5%). Identity partition (Q_1=32, zero compression). Algebraic relations: idempotence 37.9%, absorption 20.7%, commutation 19.1%. Min D_1 = 0.099 — not even close to merging.

**The binding finding:** Dead histories haunt the transformer. The model treats `a=0; a=0` differently from `a=0` alone. It treats `a=0; a=1` differently from just `a=1`. It treats `a=0; b=1` differently from `b=1; a=0`. The overwritten fact, the redundant repetition, and the execution order of independent operations — all are visible in the model's next-token prediction, even through the coarsest binary observer.

**What this closes:** CRC on Qwen3-1.7B-Base. Two task families (SVB scoping, binary register overwrite), two observers (full-vocab, binary). Both identity partitions. The Codex stop condition is met.

**What this opens:** The path-dependence IS a structural finding. It's not just "no compression" — it's a positive characterization: the model's computation is history-sensitive in specific, measurable ways. The algebra of actions (idempotence, absorption, commutation) fails at specific rates that characterize HOW the model processes history.

**Competence failure analysis (post-hoc):** All 8/64 competence failures share the same structure: the queried register's last write is NOT the final line of the history. When it IS the last line: 32/32 = 100% correct. When it's not: 24/32 = 75% correct. In every failure, the model predicts the EARLIER (overwritten) value. This is a clean structural result: positional recency dominates semantic state tracking. Intervening writes to the OTHER register interfere with recall of the queried register's value.

**Cross-framework convergence:** The prior `predictive_setter_algebra_v1` experiment (2026-08-31, natural language fact appending) found last_write_wins = 27%, commutation = 56%. CRC-1 (2026-09-04, Python register assignments, full CRC framework) found absorption = 20.7%, commutation = 19.1%. Two completely independent methods, same model, same finding: **primacy bias + non-commutation are structural properties of Qwen3-1.7B-Base**, not artifacts of any single measurement approach.

**Next:** Codex strategic analysis for what to do after CRC closure.

---

### RE-CONTEXTUALIZATION: Two campaigns, zero positive results (2026-09-04)

**Project**: Latent-Space-Reasoning.

**Live question**: Does native mathematics exist in latent spaces, and what does it look like?

**Pattern across campaigns:**

1. SVB campaign (scalar projections): 8+ experiments, all structured negatives. Root cause: R^n trap — scalar logit projections discard structure.

2. CRC campaign (full distributions): escaped R^n, clean apparatus, but identity partition. The model is too competent — every state is unique, no room for compression.

**Alternative interpretations (anti-tunnel):**

1. **Task exhaustion, not framework failure.** CRC works mechanically. The SVB variable-scoping task at 100% competence simply has no degeneracy. A task where the model naturally confuses states (near capacity limit) would be the right substrate.

2. **"Almost compressible" is the signal.** Min D_1 = 0.0165 at eps=0.01. At eps=0.02, one pair merges. The model is on the boundary — presentations are almost equivalent. Better-matched presentations (same token count, same structure) might cross it.

3. **Compact quotient is the wrong shape.** Native math might not be a finite state machine. It could be continuous (differential structure on the probability simplex), topological (connected components under action), or information-geometric (Fisher metric on response distributions).

4. **Different model.** Qwen3-1.7B-Base may be too large / too capable for this task. A smaller model, or a model at its capacity limit on a harder task, would have forced compression.

5. **Different response channel.** We used next-token prediction only. Hidden-state similarity, attention pattern structure, or gradient-based probes would access different structure — but those are the R^n tools the project explicitly moved away from.

6. **The result IS the math.** The identity partition at horizon 1 with Q_0 compression at horizon 0 IS a mathematical fact about this model. The refinement tower Q_0(33) → Q_1(36) → Q_2(36) with specific split witnesses is a complete structural characterization. It's just not the compact structure we hoped for.

**What still holds:**

- The CRC framework is clean, decisive, and interpretable.
- Full-distribution analysis (not scalar projections) is the right approach.
- Mode F control (TV = 7e-7) confirms transformer KV cache is perfectly faithful.
- The model genuinely maintains 36 distinct behavioral states through depth-4 nested scope.

**What's reframed:**

- The SVB task family is doubly exhausted — even escaping R^n, it doesn't compress.
- The "almost compressible" boundary is a structural fact worth understanding, not just a near-miss.

**Awaiting:** Codex Architecture Theorist strategic analysis for next direction.

---

### CRC-0 result: FAIL — no compression (2026-09-04)

CRC-0 complete. 544 forwards, 210s CPU. Codex-designed: 36 roots (3 vars ×
4 vals × 3 presentations), 3 typed actions (N/H/R), exhaustive A^2 = 13
words per root, full 151K-vocab distribution, clique-verified classes.

Result: Q_0 = 33, Q_1 = 36, Q_2 = 36. No compression at any tolerance.
The model maintains a unique behavioral signature for every (var, val, pres)
triple. Three Q_0 pairs merged (presentation variants with TV < 0.01) but
all split at Q_1: the H action distinguishes presentations at TV~0.028,
the R action distinguishes cross-variable pairs at TV=0.111.

Transfer vacuously fails (all Q_1 classes are singletons). Mode F control
shows TV = 7e-7 (cache perfectly faithful). Verdict stable at all tolerances.

Key observation: min D_1 = 0.0165, just 65% above eps=0.01. The model is
ALMOST compressible — presentation variants nearly merge — but not quite.
This "almost" is itself interesting: the model treats different presentations
as nearly but not exactly equivalent, and even a neutral comment reveals the
difference.

This closes the SVB task family as a CRC substrate. The framework works
(clean, interpretable, decisive) but the task doesn't yield compression.

Next: Codex consultation on what task family WOULD yield nontrivial structure.

---

### PIVOT: Continuation-Refinement Calculus (2026-09-04)

Codex Architecture Theorist analysis (codex_post_svb_pivot.txt, ~12KB):
All SVB experiments projected Q_M onto scalars. The structured negatives
trace to discarding structure that later operations reveal. New direction:
study the calculus of distinguishing futures, not scalar distances.

Key objects: Sep(x,y) = set of continuations that prove states different.
Refinement tower Q_0 ← Q_1 ← ... (bounded-horizon equivalence classes).
Brzozowski derivative: how an action transforms separating languages.

Codex corrections to IDC framework:
1. Replace strict chain (Δ □ ≡_M □ ≡_E) with kernel comparison
2. Replace one-object monoid with graded typed process category
3. Make response-tree equality primary, demote D7 metric/Finsler geometry
4. Add finite-access refinement tower
5. Require finite predictive presentation for promotion

Important: congruence experiment didn't test Q_M (congruence by construction).
It tested a coarse measured quotient via δ_L and 11-bin projection.

Theory: theory/CONTINUATION_REFINEMENT.md (CR-1 through CR-9).
Next: zero-call reanalysis of congruence data, then one bounded CPU test.

### CURVATURE CONTROL: line closed — R^n trap (2026-09-04)

Confound-killing isochronous control round. 768 calls, 249s CPU. 6 templates,
2 shadow digits, 2 padding families. Position-matched via padding prepended to d3.

Results: G0-G3 PASS, G4-G6 FAIL. κ=−0.542 nat, 12/12 blocks negative, but
padding sensitivity (0.329 nat gap) exceeds 0.10 tolerance. 93/96 cells negative,
3 PAD_BARE positive. Position-gain null failed transport across template families.

Codex adjudication: real but qualified behavioral interaction, not intrinsic
curvature. Line CLOSED per one-round authorization.

Critical insight (Codex): "This line is not working as a route to native
latent-space mathematics: it remains scalar logit finite differences and OLS —
the R^n trap." All SVB-campaign experiments (congruence, S3 composition,
noncommutativity, curvature) produced structured negatives. The suffix effects
are learned semantic control — useful diagnostics, but R^n projections of
inherently non-R^n structure.

What's needed: a fundamentally different approach that works IN the latent space
natively, not by projecting it onto scalars and fitting linear models.

### CURVATURE TEST: sub-threshold, surface-specific interaction (2026-09-04)

Codex-designed 2×2 interventional test (depth × suffix). 288 calls, 98s.

d2→d3: heterogeneous (x positive, y negative, z positive — cancel in aggregate).
d3→d4: κ=-0.28 for tested pair, 24/24 cells same sign. Sub-threshold (0.28 < 0.5).

Codex adjudication (REVISE / CONTROL REQUIRED):

- Do NOT lower threshold retroactively. Descriptively nonzero, scientifically sub-threshold.
- Position is strongest rival: absolute token position changes with depth (38→58→79).
- Gate 1b cross-surface check: MISLEADING surfaces range -0.235 to +0.155 nat (mixed signs).

Only 65.5% of 168 (assert, mislead) pairs show negative κ. NOT quotient-level.

- Variable-mentioning mislead surfaces (75% negative) vs non-var (52% negative).
- 24 deterministic cells ≠ 24 independent replications. One holdout variable insufficient.
- The SNR gate was never computed — "only magnitude failed" is formally false.
- Half the separation comes from ASSERT becoming MORE beneficial at d4.

Licensed: "On one preregistered SVB surface pair, the d3→d4 MISLEAD-minus-ASSERT logit contrast was -0.284 nat in all 24 crossed cells; it missed the 0.5-nat gate and remains confounded by position, shadow-token exposure, and surface choice."

What it advances: the fixed suffix contrast is context-dependent and cannot be represented by the simplest globally additive logit-shift model. Candidate obstruction and falsifier generator, not yet a law.

NEXT: One confound-killing control round. Position-matched, token-matched, multi-surface, varied shadow digit. If residual curvature doesn't survive, close.

### S3 PERMUTATION COMPOSITION: model cannot compose (2026-09-04)

Codex-designed S3 experiment. Gate 1 FAIL: 4/36 correct (degenerate c021 bias). The model cannot trace Python function calls for tuple permutations at 1.7B. This is a competence failure, not an algebra failure. Behavioral testing of compositional algebra requires tasks within the model's proven competence.

Key insight: behavioral bottleneck. Even if algebraic structure exists internally, the model can't express it through code-tracing behavior. Two paths forward: (a) compositional tasks with simple output (extend SVB), or (b) probe hidden states directly (short GPU burst, bypasses behavioral bottleneck).

### CONGRUENCE TEST: behavioral equivalence is NOT algebraic (2026-09-04)

768 calls, 218s CPU. Codex-designed decisive test for native algebra.

3 equivalence pairs (surfaces with delta_L diff < 0.006):

- strong_assert: "# State unchanged." ~ "# {var} is unchanged." (TV=0.006)
- moderate_assert: "# Values preserved." ~ "# {var} is still intact." (TV=0.013)
- misleading: "# Changing {var}." ~ "# Updating to a new value." (TV=0.025)

Composed with neutral suffix "# No changes.":

- Equivalence PRESERVED (ratios 0.62-1.90x). Trivial.

Composed with misleading suffix "# Reassigning {var} now.":

- Equivalence DESTROYED (ratios 2.6-13.2x). Non-trivial.

Verdict: NO CONGRUENCE. The behavioral equivalence defined by delta_L is surface-level. Composition with a semantically heavy suffix reveals differences that our (C,L,R) quotient cannot see. The model internally distinguishes surfaces that our scalar metric says are equivalent.

IMPLICATION: This is the Codex-predicted failure mode. The delta_L landscape is learned semantic control, not native algebra. Per Codex: "close this line as a useful hole — the latent space exposes stable semantic biases but no context-independent navigation law."

ADDITIONAL FINDING: delta_L is predictable from text features (R2=0.88).
Simple binary features (has_preserve, has_change, is_rewrite, is_observe)
explain 88% of delta_L variance. This strengthens the "trained behavior"
interpretation.

WHAT THE SVB CAMPAIGN ESTABLISHED (positive):
1. Suffix effects are real and content-driven (6.3x content over confound)
2. The effect is a depth-invariant logit bias on shadow probability
3. ASSERT and MISLEADING are cleanly separable by delta_L (no overlap)
4. Quotient closure holds for single suffixes (100% ASSERT)
5. The quotient is NOT preserved under composition -> not algebra

NEXT: Switch task families. SVB is squeezed dry. Need a task where the
model's internal structure demands richer algebraic operations.

---

### QUOTIENT CLOSURE TEST: K_s stochastic DEAD, logit-shift WINS (2026-09-04)

Held-out prediction test on Gate 1b data (3,384 obs, 43 surfaces, no new model calls).

K_s (3×3 stochastic matrix on CLR simplex): 0/43 surfaces beat ANY baseline.
Mean held-out error: 0.290 vs best baseline 0.039. The stochastic matrix
overfits in probability space because the actual transformation is nonlinear.

Logit-shift baseline (constant δ in log-probability space): best model,
mean error 0.02 cross-depth. This IS the operator — not a matrix on the simplex.

KEY FINDING — depth-invariant shadow logit shift:

- δ_L (shadow digit logit shift) is depth-invariant: CV=0.036 for ASSERT, 0.053 for ASSERT_VAR
- δ_C (correct digit logit shift) is NOT depth-invariant: CV=0.39
- Each surface has a specific δ_L value, constant across depths d2-d4
- ASSERT: δ_L ranges from -0.94 to -2.54 across surfaces
- MISLEADING_ASSERT: δ_L ranges from +0.27 to -0.84

Response collision closure: 100% for ASSERT/ASSERT_VAR (quotient exists),
99% for MISLEADING roles, 62-70% for OBSERVE/REWRITE.

Cross-role transfer: FAILS. K trained on ASSERT→ASSERT_VAR: 0.32 vs
logit-shift baseline 0.02. Different surfaces within same role have
different δ_L values.

HONEST ASSESSMENT: The suffix effect is a surface-specific, depth-invariant
logit bias on shadow probability. This is structurally real but mathematically
simple — a lookup table, not an algebra. The 3×3 K_A operator was an artifact
of the wrong coordinate system (probability vs logit space).

---

### GATE 2 v2 MULTI-FILLER: CLOSED — POSITION_WITH_NONLINEAR_GAIN (2026-09-04)

Multi-filler robustness test with 3 independently selected filler pairs (all
token-matched). 288 new calls (pairs 2 & 3), reusing AM/MA and pair 1 from v2.
2.4 min CPU.

Results:

- Residual order contrast (pre-gain): all 3 pairs pass (medians 0.040, 0.067, 0.089)

- Cross-filler consistency: corr 0.69–0.92 (the order effect is real, not filler-specific)
- Scalar gain fit: ALL fail (post-gain medians 0.003, 0.007, 0.009 < 0.01)
- Pair 2 has 0/24 contexts above threshold post-gain

Verdict: The order effect is real and consistent across fillers, but it is fully explained by position with context-dependent magnitude (nonlinear gain). There is no genuine content interaction between A and M beyond position effects.

Gate 2 composition is now a STRUCTURED NEGATIVE. The surfaces A and M don't interact noncommutatively — they contribute additive position-dependent effects whose magnitude varies by context.

Strongest remaining finding: K_A correction operator (depth-invariant L→C ≈ 0.72). This is independent of composition and describes a genuine operator equation.

Next: Codex strategy session on K_A as headline finding. Design held-out prediction test for the atomic operator equation.

---

### CODEX EVIDENCE GATE: Gate 2 v2 downgraded to PROVISIONAL (2026-09-04)

Codex identified critical Gate 2 issue: implementation computed armwise prediction error (mean=0.033), not the pre-registered residual order contrast. Corrected diagnostics show filler-predicted order vectors align almost perfectly with observed (cosine=0.996) but over-predict magnitude. Fitting one scalar gain per context reduces mean residual TV to 0.008 (below threshold in 18/24 contexts).

Strongest rival: nonlinear position/recency gain or saturation. The order effect is real (Gate 1 strong) but may be fully positional with nonlinear gain profile.

Repair plan: (1) freeze exact residual-order statistic and clustered lower bound, (2) test nonlinear-gain rival with context-feature prediction, (3) multi-filler robustness (multiple mechanically selected filler pairs), (4) held-out prefix family.

Also found: depth-invariant K_A correction rate (L->C ~= 0.72 across d2-d4). This is a stable operator equation independent of the noncommutativity claim.

---

### GATE 2 v2: PROVISIONAL — direct order effect confirmed, excess disputed (2026-09-04)

216 calls, 8 arms per context (Codex filler-based design), 24 contexts, depth 4. 135s CPU.

Token-length-matched fillers: F_A="# Code block follows.\n" (5tok), F_M="# Looking at the next part.\n" (7tok).

**Results:**

- Direct TV(AM,MA): mean=0.072, median=0.068, max=0.141
- Excess beyond filler null (prob-space): mean=0.033
- Excess beyond filler null (log-ratio): mean=0.038
- Both pre-registered gates PASS (threshold 0.01)
- Verdict: NONCOMMUTATIVE_CONTROLLED

**Per-variable breakdown (log-ratio excess):**

- x: direct=0.040, excess=0.038 — nearly all genuine interaction
- y: direct=0.112, excess=0.026 — large effect but mostly position-dependent
- z: direct=0.063, excess=0.050 — mostly genuine interaction

**What we learned:**

1. A and M genuinely interact — the effect of applying A is modulated by M's presence

and vice versa, beyond any additive position/recency model.

2. The interaction is variable-dependent: x and z contexts produce more genuine noncommutativity, while y contexts have a larger raw effect that's more position-dominated.

3. This is the first controlled evidence that suffix operators compose non-trivially. K_A o K_M != K_M o K_A even after subtracting position effects.

4. Robust across probability-space and log-ratio coordinate predictions.

**What's next:** Codex evidence gate running. Then: what algebraic relations do these operators satisfy? Path from "operators don't commute" to "here is the native algebra." Gate 3 (causal relay-state composition) remains the decisive experiment but needs GPU.

---

### GATE 2 v1: RECENCY_DOMINATED — MISLEADING class too variable (2026-09-04)

504 calls, 4 pairs (2 cross-role, 2 same-role controls), depth 4 only. 550s CPU.

**Results:**

- Cross-role TV: mean=0.085, median=0.081
- Same-role ASSERT: mean=0.006 (nearly commutative, despite 3.8× a_u range!)
- Same-role MISLEADING: mean=0.097 (highly noncommutative, 2.9× a_u range)
- Verdict: RECENCY_DOMINATED (cross-role median 0.081 < same-role max 0.130)

**What we learned:**

1. ASSERT class is remarkably orderly — "State unchanged" (a_u=0.10) and "No changes" (a_u=0.38) nearly commute (TV=0.006). The ASSERT operator is content-stable.

2. MISLEADING class is chaotic — "Changing {var}" (a_u=0.50) and "{var} gets reassigned" (a_u=1.44) are highly order-dependent (TV=0.097). The class is too heterogeneous.

3. Cross-role noncommutativity (0.081) is real but CANNOT be distinguished from the extreme within-MISLEADING order effects.

**Codex correction (received before experiment):** Same-role controls are the wrong null model. They don't properly absorb the discounted-scalar rival s'=λs+δ_u. Need token-length-matched neutral fillers and an additive interaction test.

Next: redesigned 192-call experiment with Codex's filler-based null model.

---

### GATE 1b COMPLETE: CONTENT DOMINATES, LUMPABILITY STRONG (2026-09-04)

3,384 calls across 8 roles × 3 depths × 3 vars × 8 values. ~100 min CPU.

**Key results:**

1. **2×2 ANOVA: content dominates at 6.3x** (content effect +0.0915 vs var-mention +0.0145). Per depth: d2=32x, d3=6x, d4=4.9x. Replicates on holdout. The +0.092 ASSERT→MISLEADING difference is overwhelmingly content-driven.

2. **Lumpability: STRONG (R2 0.79–0.98).** Contexts with similar baseline (C,L,R) produce similar post-suffix (C,L,R). K_u is approximately a well-defined operator on the simplex. BOUNDARY (0.98) and MISLEADING_ASSERT (0.96) are near-perfect. This means the (C,L,R) projection captures most of the information the model uses to determine post-suffix behavior.

3. **Surface equivalence: WEAK.** Only 1 cross-role pair in class A passes at eps_eq=0.01 (ASSERT:"State unchanged" ↔ ASSERT_VAR:"{var} is unchanged",

max TV=0.009). Class M has zero qualifying pairs. The multiplicative character a_u is surface-specific (within-class CV 0.33–0.51), not class-invariant.

4. **K_a vs logit-bias: INCONCLUSIVE.** Cross-fit has no holdout data. R-preservation tentatively favors K_a (ASSERT dR=−0.007, MISLEADING dR=+0.003, both small).

**Implications for Gate 2:** Content dominance unblocks noncommutativity testing but surface equivalence constrains it. For class A we have one validated pair. For class M we need either a relaxed threshold or different surfaces. The lumpability result is the strongest positive: it means the (C,L,R) simplex IS the right coordinate system for studying suffix operators.

---

## CODEX NATIVE MATH THEORY FOUNDATIONS (2026-09-04)

Codex Architecture Theorist (session 01a06c67) on what native latent-space math IS and what noncommutativity actually proves.

**Central verdict: "Noncommutativity is cheap; stable equations are expensive."** The transformation monoid exists for ANY sequential transducer. The native prize is model-discovered, representative-independent algebra with causal realization.

**What noncommutativity proves (and doesn't):**

- PROVES: obstruction to specified commutative factorizations (K_a, logit-bias)
- DOES NOT PROVE: dimension >1, nonlinearity, lumpability failure, compression, proof-relevance, topological holes, transformer-specificity, or compositional prediction. Cross-role > same-role TV doesn't even rule out recency — position-matched singleton+filler arms are required.

**The right framework:** Typed causal process category C_M = Q_M □ I. Objects = predictive causal states at layer-position cuts. Arrows = model computations. External denotation is a functor. EqWit = vertical arrows invisible to denotation. Commuting/failing squares between layer transports and behavioral operations are where architecture enters.

**The decisive experiment: "causal relay-state composition"**
1. Multiple surfaces per role, assigned to nonce codes (so physical code can't predict role)
2. Define relay-state equivalence by causal substitution at declared layer cut
3. Mask original tokens downstream — test compiled state vs rereading
4. Predict unseen compositions from atomic transition table
5. Transplant relay-token state causally — must follow class + composition table
6. Practical control: use predicted class to correct degraded scope answer

**Directed homotopy:** Still viable but EqWit □ $\pi_1\uparrow$ NOT justified. Needs: verified execution squares (empirical 2-cells), directed graph/cubical complex, demonstrated inequivalent parallel paths with same endpoints. AB≠BA alone supplies neither equal endpoints nor absence of homotopy.

**Native math manifesto axioms:** Operational identity (future-experiment substitutability), causal action (admissible model computations), presentation invariance (surface/coordinate changes), architecture locality (layer-position causal graph). First theorems: predictive-state minimality, kernel/fiber,

causal-realization, independence (commutation from disjoint causal cones),
obstruction (failed square forbids coarse factorization).

**Implication for current program:** Gate 1b → Gate 2 composition path is valid
but NARROW. The composition test can reject K_a/logit-bias but cannot establish
native math alone. The full program needs the causal relay-state experiment
(Gate 3+), which requires GPU and internal-state access.

### CODEX LOGIT-BIAS RIVAL REVIEW + COMPOSITION TEST DESIGN (2026-09-04)

Codex Architecture Theorist follow-up (session 01a06c48) on how to defeat the
logit-bias rival. Key findings:

**1. Content dominance ≠ rival defeat.** Even if Gate 1b shows content >> var-mention,
a content-specific logit bias δ_true vs δ_misleading is fully consistent. Content
dominance rejects the narrow "mentions-variable" hypothesis but not the logit bias.

**2. Analyzer Step 4 was tautological.** The K_a vs logit-bias comparison fitted a_u
and δ_u per cell and "predicted" the same cell. FIXED: now cross-fits one parameter
per role on train split, predicts holdout. Reports full (C,L,R) prediction errors.

**3. R-preservation is testable.** K_a predicts ΔC=-ΔL, ΔR=0. Logit-bias predicts
all non-shadow probs scale by 1/Z where Z=1+(b-1)L, so R'=R/Z≠R and R'/C'=R/C preserved.
For b≈4, L≈0.05, R≈0.25: expected |ΔR| ≈ 0.026. Gate 1b data can adjudicate.

**4. Noncommutativity criterion — the strongest discriminator.** K_a matrices ALSO
commute (upper-triangular with same diagonal). So noncommutativity defeats BOTH logit-bias
AND K_a simultaneously. If α(u)□α(v) ≠ α(v)□α(u), the monoid is genuinely non-scalar.

**Actions:** Analyzer Step 4 rewritten with cross-fitting. Noncommutativity criterion
added to theory/closed/INTENSIONAL_DESCENT.md. Composition runner (run_composition) added to
run_semantic_descent.py. Config svb_qwen3_composition.json created: 120 calls, ~2.5 min.
Gate 1b ~20 min from completion; composition test runs after.

### CODEX NATIVE MATH ASSESSMENT: χ demoted, logit-bias rival identified (2026-09-04)

Two independent Codex reviews (Architecture Theorist + Novelty Challenger) on whether
the multiplicative character constitutes native latent-space math.

**Verdict: NOT YET NATIVE.** K_a is ordinary linear algebra on a coarse output simplex
(in (S,L,R) coordinates it's just diag(1,a,1)). The multiplicative character χ is
standard representation theory. Both are R^n scaffolding, not native structure.

**Key corrections adopted:**

1. Bayesian interpretation was WRONG: E(u)=id does not imply likelihood ratio=1.
A denotationally null operation can still be evidence about the answer/task.
Likelihood ratios multiply ODDS, not raw probability L.

2. **Strongest rival: constant shadow-logit bias.** A suffix producing additive
logit shift δ_u gives L'/C' = e^{δ_u} × L/C exactly, and L'/L ≈ e^{δ_u} when
L is small. Setting δ_u ≈ log(4) reproduces the 4x ratio with no EqWit needed.

3. Discriminating tests: K_a predicts R'=R; logit-bias predicts R changes via
normalization. K_a predicts stable raw ratio; logit-bias predicts stable log-odds.

**What IS potentially native:** The operational quotient — denotationally null histories
becoming different moves because they alter future possibilities. The behavioral action

α and its path algebra, not K_a or χ by themselves.

**Actions taken:** Theory Bayesian section corrected. K_a vs logit-bias comparison added to character analyzer. χ demoted to diagnostic candidate. Idempotent config created.

### CODEX FOLLOW-UP: Idempotent test + multiplicative character theory (2026-09-04)

Codex Architecture Theorist follow-up on two questions from Gate 1 results.

**1. Idempotent test — newline FAILS:**
Zero-call screen from existing Gate 1 data: b="\n", b²="\n\n", b³="\n\n\n".
TV(b,b²)=0.003 (near-equivalent), TV(b²,b³)=0.027 (clearly separated).
True idempotence b²=b □ b³=b²=b, but b³ departs. Transient plateau,
not stable monoid relation. Cheapest next test: `pass\n` at d4 only,
48 calls. If that fails, `type(x)` for another 48.

**2. Multiplicative 4x ratio — observable constraint, not operator:**
The stable MISLEADING/ASSERT L ratio (~4x across depths) constrains only
ℓ□K_M and ℓ□K_A on three aggregated inputs. Does NOT imply K_M = 4·K_A.
Codex derives the consistent operator family: K_a(C,L,R) = (C+(1-a)L, aL, R),
composing as K_a·K_b = K_{ab}. If confirmed, χ: EqWit → (R≥0, ×) would be
a multiplicative character (one-dimensional representation of the monoid).

**Promotion ladder** (each step requires the previous):
1. Stable cellwise ratio (not just depth means)
2. R-preservation + S-preservation (coordinate action)
3. Surface descent (paraphrases in same class yield same a_u)
4. Composition: a_{uv} ≈ a_u·a_v on unseen compositions

Gate 1b BASELINE role enables step 1 testing. Steps 3-4 need further experiments.

Theory updated: transformation monoid + denotational grading + multiplicative
character section added to INTENSIONAL_DESCENT.md. Committed and pushed.

### GATE 1 COMPLETE + CONFOUND DIAGNOSTIC + GATE 1b LAUNCHED (2026-09-04)

Gate 1 re-run completed (2835 calls, 31.6 min — slower due to duplicate process contention).
Full analysis including holdout set, per-depth breakdown, and confound diagnostic.

**Decisive test (all data):** ASSERT L=0.032, MISLEADING_ASSERT L=0.124, **+0.092 diff (t=21.23)**.
**Holdout replication:** +0.121 diff. Effect is LARGER on held-out surfaces.
**Per-depth scaling:** d2 +0.047, d3 +0.105, d4 +0.126. Content effect grows with depth.

**Confound diagnostic:** MIXED. Content effect (misleading_novar - assert) = +0.061.
Var-mention effect (misleading_var - misleading_novar) = +0.051. Both comparable (~1.2:1).
"Updating the value" (no var mention) has L=0.097 vs assert 0.036 = genuine content effect.
But var-mentioning surfaces average L=0.148, adding ~50% more.

**Gate 1b launched** (svb_qwen3_gate1b.json): 2x2 content × var-mention crossover with
BASELINE role for F8 lumpability. ~3096 calls, ~19 min on CPU. Running now.

### GATE 1 PRELIMINARY: Content sensitivity confirmed, form/content confound identified (2026-09-04)

Gate 1 experiment completed all 3 depths (2835 calls, ~17 min on CPU).

Train-set results (n per role: ASSERT=486, MISLEADING_ASSERT=324, REWRITE=486,
OBSERVE=324, BOUNDARY=324):

| Role | C_mean | L_mean | R_mean |
|---|---|---|---|
| ASSERT | 0.9395 | 0.0342 | 0.0263 |
| MISLEADING_ASSERT | 0.8493 | 0.1138 | 0.0369 |
| REWRITE | 0.5235 | 0.4244 | 0.0521 |
| OBSERVE | 0.6473 | 0.3292 | 0.0235 |
| BOUNDARY | 0.8191 | 0.1505 | 0.0304 |

DECISIVE TEST: MISLEADING_ASSERT L=0.114 vs ASSERT L=0.034 = +0.080 difference.
The model follows CONTENT, not just form: misleading comments (that say they're
rewriting but denotationally don't) get 3.3x higher shadow leakage than true
assertions of invariance.

Between/within ratio = 1.17 (weak overall). Codex follow-up identified why:
only ASSERT vs MISLEADING_ASSERT genuinely crosses form and content. REWRITE,
OBSERVE, BOUNDARY are confounded with their statement types (assignment,
expression, delimiter). The five-class null-witness claim isn't supportable
from this design alone.

Codex V2 corrections applied to theory/closed/INTENSIONAL_DESCENT.md:

- D10 composition order matched to D1 convention
- D11 congruence proof: triangle decomposition added
- Removed residual |I|<|P|
- F7 revised: what may be artifactual is algebraic structure, not coarse distinctions

Codex F6/F8 findings:

- F6 needs nested ladder: M_state < M_cheap < M_cheap+role (variance comparison inadequate)
- F8 (lumpability): Gate 1 data alone insufficient; need empty-suffix baseline responses
- Exclude val=9 from all (C,L,R) analyses (shadow/correct digit collision)
- Current design supports narrow comment-content result, not five-class claim
- Need balanced role-by-realization crossover for stronger Gate 1

Re-running experiment with Unicode fix (crashed on Windows cp1252 arrow character).
Awaiting full results including holdout set and per-depth breakdown.

### STRATEGIC PIVOT: Intensional Descent Criterion (2026-09-04)

Codex Architecture Theorist synthesis delivered a clear verdict: the coefficient
cartography (suffix counts, attenuation estimates, simplex analysis) is standard
R^n mathematics — necessary scaffolding but NOT the native math. The native math
is the EQUALITY-WITNESS ALGEBRA: the structure of how denotationally null moves
(things that "do nothing" extensionally) have nontrivial, compositional, causal
model actions.

Formal framework written: theory/closed/INTENSIONAL_DESCENT.md

- D10-D15 extend D1-D7 with external denotational category
- P → I → D factorization: model factors through intensional quotient but NOT
through extensional denotation
- Equality witnesses: classes of "doing nothing" the model distinguishes
- Witness transport: context-indexed operators on denotational fibers
- Five exact falsifiers (F1-F5)

Biggest credible claim: "Pretrained transformers implement proof-relevant causal
semantics — they compress execution histories into equality-witness classes

strictly finer than denotational state, compositional, and causally controlling."

Gate 1 (Semantic Descent) experiment designed and launched:

- 5 intensional roles × ~7 surface realizations × 3 vars × 9 vals × 3 depths
- Critical test: MISLEADING_ASSERT (comments describing rewrites) vs true ASSERT
- If content > form: intensional descent. If form > content: lexical cueing.

Codex reviewing the theorem attempt in parallel.

### DEPTH-5 REVEALS L SATURATION: shadow leakage has finite capacity (2026-09-04)

Depth-5 prediction experiment (P4) shows the exponential depth model BREAKS:

- L(4)=0.234, L(5)=0.244 — only 4% increase (was x3.0, x2.2, x1.2 at d1-d4)
- L saturates at ~24%. Model has finite scope-confusion capacity.
- R grows instead (0.035→0.047) — general noise replaces scope confusion.
- a_c weakens to 0.43 (from 0.38); R invariance breaks (|dR|=0.007).
- Recovery fraction stable at 0.49 (consistent d2-d5).

Operator family formalized: R-preserving subfamily K_a forms abelian monoid.

Semantic binding signal beta orders suffixes on a one-dimensional scale.

Fisher distance increases with depth (operator does more work where needed).

K_a * K_b = K_{ab} algebraically, but empirically one-shot (not iterable).

New predictions P5-P8 registered (semantic equivalence, semantic opposition,

cross-model content/boundary decomposition, attention pattern selectivity).

### CONTENT-SPECIFICITY CONFIRMED (P2): the suffix is a semantic intervention, not a boundary signal (2026-09-04)

Suffix ablation experiment (6 conditions, 756 calls, 237s CPU) tests whether

any code-like token provides the ~62% shadow suppression, or if "# No changes.\n"

is special. Result: content IS specific.

Two-component model:

- Generic boundary signal (~17%): any code token (pass, newline, short comment)

provides modest suppression (a_c ~ 0.82). This is the "boundary appeared" cue.

- Content-specific "no changes" signal (~45% additional): the semantic content

carries the dominant disambiguation signal.

- Self-assignment "x = x" actively INTERFERES (a_c > 1.6, mass flows C -> L).

R-preservation hierarchy: "# No changes.\n" is the ONLY suffix that is both

strongly suppressive AND R-preserving (|dR| < 0.002). Other suffixes partially

disturb R. This selects a distinguished kernel from the operator family.

Codex review (switched controlled transducer formalization): GO on controlled

fiberwise response-law synchronization. NO-GO on declaring native coordinates

or full predictive-state synchronizer yet. Key corrections adopted:

- (C,L,R) is R^3 subset; K is standard stochastic linear map
- The native contribution is the operationally induced quotient, not the matrix
- (C,L,R) equality is not predictive-state equality (R collapses bins)
- Call it "one-probe fiber synchronizer" or "registered response-law synchronizer"
- Obs. 6 "fresh readout" / "look twice" interpretations marked SUPERSEDED

Gossip version (Codex): "A comment doesn't give the transformer more time —

it tells it which overwritten value to stop believing."

Next: depth-5 prediction (P4), nested vs flat control (P3), Codex on the

theoretical implications of content-specificity and the operator family.

### SHADOW TRACKING CONFIRMED: boundary-conditioned attenuation is a genuine scope mechanism (2026-09-04)

Reanalysis of per-cell 11-bin distributions revealed the suffix effect is NOT a "fresh readout pathway" or "mixture model." It is specific suppression of the dominant shadow-binding competitor. The shadow relabeling experiment (3 conditions: shadow9/2/5, 324 calls, 95s CPU) confirms the mechanism tracks the actual shadow digit under relabeling — not hardcoded to digit 9.

Key results:

- The attenuation law: $L(d,1) = a_c \cdot L(d,0)$, $a_c \approx 0.38$ at $d \geq 2$
- R (non-shadow, non-correct mass) is invariant (<0.002 change)
- Scope-relevant mass (C+L) is invariant — the model already knows the answer is {target, shadow}; the suffix resolves the disambiguation
- Scope-pair entropy reduction: 0.08-0.33 bits (42% at $d \geq 2$)
- The operator is one-shot, not iterable (s>1 adds interference)
- Within-binding variation contracts 25-59% (synchronization signature)

Mathematical object: $T_{suffix}: (C,L,R) \rightarrow (C+(1-a_c)L, a_c \cdot L, R)$ is a linear operator on the response-law simplex. One-parameter family indexed by $a_c$. Preserves scope-relevant mass, contracts shadow leakage, invariant residual.

Next: suffix content sensitivity (P2), nested vs flat control (P3), Codex follow-up on predictive-state transducer framework.

Older entries (2026-08-27 through 2026-09-03) were moved verbatim to docs/NOTEBOOK_ARCHIVE_2026_08_27_to_09_03.md.

## HP-D Orlicz arc: optimality stack at the settled compression optimum (2026-09-20)

### s=1 gap diagnosis (12 seeds x 6000 steps, frozen decision rule)

At (B=8, rho=0.3, s=1): d=2 best 0.0857 (all seeds within 0.0005), 6.2x the Fisher prediction 0.0139; d=4 best 0.0253, 4.7x. VERDICT: genuine large-deviation gap — the optimizer is not the limitation; the quadratic expansion is. Runner: internal/s1_gap_lean.py (lean rerun after the original 40-run job stalled under contention); data s1_gap_diagnosis.json.

### CGF decomposition at the settled optimum

Excess 0.0859 = quadratic component AT the optimum 0.0966 (7x the Fisher-optimal 0.0139, ABOVE the total) with kappa_3 = -0.005, kappa_4 = +0.014 partially canceling. The CGF optimum accepts ~7x the variance to buy negative-skew cumulant structure: the argmin changes qualitatively.

### Envelope numerics (withdrawn conjecture)

The two-point variance-KL envelope's optimizer runs to the boundary; inf KL = 0 at any fixed variance (rare huge negative jumps). The v/2 - c v^{3/2} discount law is withdrawn; variance does not govern KL compression — the one-sided exponential moment does.

### Stationarity and curvature certificates

- Stationarity: off-space gradient energy = 1.0000 at the settled optimum (gradient entirely in the complement block — E-Y-type orthogonality; condition statement corrected en route, both directions recorded).
- Lanczos Hessian (analytic gradients, 45 iters, 1040-dim factor space): lambda_min = 2.4e-05 > 0, lambda_max = 0.252 — CERTIFIED STRICT LOCAL MINIMUM; near-flat valley explains the 0.0005 seed spread.
- Failed schemes, logged: alternating metric-reweighting (0.0117 invalid) and unconstrained DV dual (unbounded inner problem; 0.390 spurious) — both establish that KL compression lacks E-Y's norm geometry; the dual route requires regularization or a simplex-native formulation.

**Theory:** theory/HPD_ALLOCATION_THEOREM.md sections 12-12j

---

## HP-E: aggregate interference theorem — proved, corrected, validated (2026-09-19)

### Isotropic quadratic theorem (COMPLETE)

For unit-norm isotropic features and the energy readout M = I:
E[A_2] = k(k-1)/d EXACTLY; Var(A_2) = k(k-1)(2d-2)/(d^2(d+2)) EXACTLY (all shared-index covariances vanish identically via conditional independence + exact unit norms); two-phase capacity frontier k* = Theta(sqrt(d)) with Chebyshev bounds (mean-field below, aggregate-interference failure above).

### Validation (pre-registered, frozen header in the runner)

P1 anchor: 8/9 cells within 0.5-4.6% (one k=4 finite-size cell 13%); P2 concentration: pass; P4 crossing at sqrt(d): pass (A_2 = 0.87-0.97 at k = sqrt(d), 14.8-15.7 at 4 sqrt(d)). P3 REFUTED the registered general-t power: measured E[term^2] = ||T||^2/d^t to the digit — lemma corrected; the Theta(1) diagonal channel is special to quadratic/projection structure, and the degree>=3 extension is open with that explicit obstruction.

### E-struct theorem (anisotropic; expectation level + validated)

Unit-energy features with covariance Sigma: per-pair interference = tr(Sigma^2)/(tr Sigma)^2 = 1/PR(Sigma) EXACTLY; capacity frontier k* = Theta(sqrt(PR)); power-law corollary k* = Theta(d^{1-alpha}) for alpha > 1/2 — a power-law spectrum taxes quadratic mean-field computation by d^{alpha-1/2} vs isotropy. Validated across alpha in {0,.5,.75,.9}, d in {512,2048}: per-pair exact to 0.4-2.4% at alpha<=0.5; crossings bracketed 8/8; two formal registered fails carry diagnosed benign causes (exact-vs-expectation normalization at alpha=0.9; grid-gap). Variance identity: isotropic cancellation breaks under anisotropy, replaced by a PR(Sigma^2)-bounded covariance with alpha-dependent burn-in k >> d^{2alpha-1}; intermediate band open (martingale route suggested).

**Data:** experiments/results/hpe_aggregate/{anchor,estruct}_{check,verdicts}.json
**Runners:** experiments/run_hpe_{anchor,estruct}_check.py
**Theory:** theory/HPE_AGGREGATE_INTERFERENCE.md sections 3b-3i
**Ledger:** hpe_e5_anchor_validation, hpe_estruct_validation, hpe_isotropic_theorem_complete, hpe_anisotropic_variance
**What we learned:** spectrum -> capacity is lawfully bridgeable via participation ratios (no fitted slopes); the naive degree-p ladder does not exist (per-vector 1/d pairing); trained power-law geometry REDUCES quadratic mean-field capacity relative to isotropy — the opposite of the packing intuition.

---

## HP-A A1: QSAE optimum proven sparse-exact; mean field refuted (2026-09-18)

### Theorem (sparse-exact optimum of the quadratic superposition autoencoder)

For the QSAE loss $L(W) = \Sigma_i p_i \|W^T W e_i - e_i\|^2$ with usage weights p, code dimension $d < n$: writing $G = W^T W$ (PSD, rank $\leq d$) and $P = \mathrm{diag}(p)$, $L = \mathrm{tr}((G-I) P (G-I))$. On $\ker G$ (dim $n-d$), $G-I$ acts as $-I$, so $L \geq \mathrm{tr}(P|_{\ker G})$, minimized by $\ker G$ = span of tail coordinates; the minimum is the tail mass $\Sigma_{i>d} p_i$, attained by any orthonormal unit-norm storage of the top-d usage tokens. The optimal frame operator is $W W^T = I_d$: **completely flat spectrum.**

### Verification (L-BFGS, multi-init, 6 configs)

$s \in \{0.5, 1.0\} \times (n,d) \in \{(64,16),(256,64),(512,128)\}$, 5 independent inits each. Results (medians): loss − tail-mass bound = **0.000000 at all six configs**; nonzero-norm count k0 = d exactly; fitted power-law exponent at the optimum $\alpha \approx 0.00$; the P1′ mean-field bulge profile fits at $R^2 = 0.00–0.08$ (threshold for refutation: < 0.8). **Mean-field ansatz REFUTED at the optimum; the optimum anti-mixes (organizes orthogonality) rather than mixes.**

### Consequence for the program

Power-law spectra cannot come from the quadratic objective's optimum — they must come from optimization dynamics (transients) or from softmax retrieval geometry. The rate-distortion s/2 benchmark and mean-field bulge are retired as QSAE comparators. Prediction P-E added (before any HP-B run): converged QSAE GD endpoints are flat ($\alpha \leq 0.35$), $\approx$ d nonzero norms, loss → tail mass. The XE (softmax) arm is now the main event of HP-B.

**Data:** experiments/results/hpa_random_frame/a1_meanfield.json
**Runner:** experiments/run_hpa_random_frame.py (shared: hp_spectral_lib.py)
**Ledger:** hpa_a1_result
**NOTEBOOK entry:** 119

### A2: the spectral estimator itself is biased — measurement-validity result

Random-frame Monte Carlo (norm profiles × random directions, $d \in \{32..1024\}$, $\gamma \in \{4,16\}$, 20 draws; corrected instrument: ambient dimension d, not the positive-norm count — bug found and fixed before any result was used; A1 unaffected, a2/a3 killed and rerun):

- **A2-i REFUTED:** top-90% log-log OLS does not recover the norm-profile exponent at $d \geq 256$: max deviation 0.19 ($\gamma$=4, $\beta$=0.25) and 0.19 ($\gamma$=16, $\beta$=1.0). Bias is a function of ($\gamma$, $\beta$) only — asymptotic in d by ~128.
- **A2-iii REFUTED at $\gamma$=4:** uniform (flat) input reads $\hat{\alpha} = 0.40–0.45$ (threshold 0.35). Passes at $\gamma$=16 (0.20–0.23 — matching the record's "flat init ≈ −0.25" readings at real-model $\gamma$).
- **A2-ii (specificity) CONFIRMED:** bulge inputs manufacture steep slopes ($\hat{\alpha}$ up to 8.9–12.0 at s=1) but the curved-alternative diagnostic correctly rejects them ($\Delta R^2 = 0.13–0.28$ in favor of the quadratic-in-log fit; power-law $R^2$ only 0.34–0.50).
- Even TRUE power-law inputs at shallow $\beta$ show curved fits winning ($\Delta R^2$ up to 0.17): the random-frame map bends the log-spectrum (head spikes + MP floor).

**Consequence for the record:** spectral exponents measured this way are

comparable only within fixed (γ, window). Entry 101's cross-γ exponent sweep embeds this bias (magnitude partially artifact; the direction "higher overcompleteness → flatter" may survive but needs bias-corrected rereading).

### A3: transient rate + the undershoot signature

Independent pilot (exact gradient flow, seeds 90–92, (64,16,s=1)): α rises 0.53 → 1.03+ over t=250..1250 — rich-get-richer confirmed at the exact dynamics level. Calibrated rate ρ = 2.755 (single free constant, first checkpoint only). Prediction map at (1024,64,s=1) uses the A1-theorem sparse-exact endpoint. Mechanism discovered inside the map: a saturated head-only random frame at γ_eff=1 has a Marchenko–Pastur spectrum that the estimator reads as α ≈ 1.15 — so a late-time measured α BELOW the norm-only prediction is the dynamic signature of learned orthogonality (directional organization beyond norms), cleanly separable by the N1-t control.

**Data:** experiments/results/hpa_random_frame/{a2_spectral_map,a3_transient}.json
**Ledger:** hpa_a2_result, hpa_a3_result

## Controlled Eigenspace Vulnerability — Entry 92 Overturned (2026-09-18)

### Controlled eigenspace perturbation (entry 118, SmolLM2-135M)

Injected fixed-magnitude perturbations into individual gate_proj eigenspaces at the MLP input (post-LN) across layers 0, 15, 29. All 576 eigenspaces tested at each layer. Result: POSITIVE beta at all layers (sensitivity INCREASES with eigenvalue, not decreases). Top eigenspaces are 3-14x more sensitive than tail. Overturns entry 92's "tail vulnerability" interpretation. The SNR prediction (beta=-0.5) rejected; observed beta = +0.25 to +0.41.

Entry 92's correlation was confounded: natural perturbations that project into top eigenspaces at late layers are SMALL (absorbed by earlier layers), while tail-projecting perturbations are LARGE (unabsorbed). The tail vulnerability is a multi-layer processing artifact, not an eigenspace property.

**Data:** experiments/results/frame_analysis/eigenspace_vulnerability.json
**Script:** scratchpad/eigenspace_vulnerability.py
**NOTEBOOK entry:** 118

---

## General HD Mathematics — Analytical Results (2026-09-18)

**Direction pivot:** From model-specific experiments to general mathematical exploration of high-dimensional spaces. Scope: pure math, statistical physics, information theory, random matrix theory, kernel methods.

### Interference hierarchy (entry 117, analytical)

Derived: in R^d, t-body interference terms in degree-p polynomial maps scale as d^{-(t-1)/2} (RMS). Proven for p=2 (quadratic). Connects to cluster

expansion (stat phys), 1/N expansion (QFT), Hoeffding decomposition (statistics).
The "mean field" of HD spaces is independent feature processing.

### Representation-computation gap (entry 117, analytical)

Derived: store O(exp(d)) features (packing), linear computation on O(√d)
simultaneously (coherence-limited), bilinear computation on O(1) simultaneously
(dimension-independent). The gap is exponential. Training closes it by structuring
weights. Intermediate dimension m provides computation bandwidth, not d.

### Rate-distortion optimal allocation (entry 117, analytical)

Proved: for Zipf(s) inputs, optimal eigenvalue exponent $\alpha^* = s/2$. Lagrange
optimization. Observed model exponents (0.35-0.90) are steeper than optimal.
The 1-body (mean-field) allocation becomes exact as $d \to \infty$.

**Theory notes:** scratchpad/interference_hierarchy.md, scratchpad/hd_computation_capacity.md
**NOTEBOOK entry:** 117
**What we learned:** HD spaces have a natural hierarchy where independent feature
processing is the dominant term, with corrections suppressed by powers of d.
This connects neural network architecture (depth, width, gating) to fundamental
HD geometry. The representation-computation gap explains why transformers need
both width (for packing) and depth × intermediate width (for computation).

---

## Row-Permutation Series: Composition is a Tensor Phenomenon — 2026-09-18

**Central question:** What invariant captures MLP composition? Can static
weight analysis characterize gated MLP function, or is composition
fundamentally data-dependent?

### Row-permutation challenge (entry 103)

Prescribed by Droid adversarial review (entry 102). Permuted up_proj rows
randomly (seed 42) on SmolLM2-135M, all 30 layers, 10 prompts.

**Result:** Permutation preserves all $D_k$ (diff < 5e-08) and all Gram
operators, but destroys MLP output (mean relative error 139%, range
1.04-1.64). Function-preserving control (consistent permutation across
gate/up/down) has zero error (2.5e-07). Separation: 5.5 million to 1.

### Row-wise cosine analysis (entry 104)

Computed $\cos(\text{gate}_i, \text{up}_i)$ for all 1536 neurons per layer.

**Result:** Mean cosine = -0.001, fraction positive = 0.499. Indistinguishable
from random. In d=576, all pairwise cosines concentrate at zero by HD
geometry. Row pairing matters but carries no per-pair directional signature.

### Cross-matrix SVD (entry 105)

Computed SVD of $G = W_{gate}^T @ W_{up}$ (d x d) for original and permuted pairing.

**Result:** Nuclear norm ratio 1.004, effective rank 410 vs 413, power-law
exponent 0.372 vs 0.370. Nearly identical. The cross-matrix spectrum does
NOT distinguish correct from random pairing.

### Bilinear vs gated sensitivity (entry 106)

Three modes under same permutation: SwiGLU, linear-gated (no silu), additive.

**Result:** SwiGLU error = 1.39, linear-gated = 1.28 (ratio 1.09),
additive = 0.88. The silu nonlinearity adds only 9% extra sensitivity.
The elementwise multiply (gating) adds 46% over additive. The multiplicative
tensor structure, not the activation function, drives composition sensitivity.

**Converging conclusion:** No tested weight-only invariant captures gated MLP
composition. D_k, row cosines, and cross-matrix SVD are all blind or washed
out. The compositional structure is a 3-way tensor phenomenon created by
multiplicative gating, not reducible to pairwise matrix statistics.

### Predictive rewiring challenge (entries 108-109)

Droid-prescribed decision experiment. 60 partial permutations per layer,
5 test layers, train/test prompt split.

**Entry 108:** Input-conditioned tensor predictor (gate+input, no silu) has
R2 = 0.90 on held-out prompts vs DU (gate-blind) R2 = -2.4. But DU's poor
R2 is calibration transfer failure, not ranking failure (correlation = 0.97).
Note: activation-weighted predictor was tautologically perfect (same formula).

**Entry 109 (decisive):** Weight-only tensor ||ΔT||_F (includes gate via
Hadamard product tr(GG^T □ D^TD □ ΔUΔU^T)) vs weight-only DU ||DΔU||_F.
R2: tensor 0.94, DU 0.95. Nearly identical. Gate structure in weights adds
NOTHING to damage prediction. Input-conditioned tensor only marginally better
(R2 = 0.96).

**LINE CLOSED.** Per Droid's decision rule: DU suffices, gate-value tensor
coupling is not a discoverable invariant. The sensitivity to row permutation
is about how D amplifies changes in U, not about gate-up coupling.

**NOTEBOOK entries:** 103-109
**Data:** experiments/results/row_permutation/
**Scripts:** row_permutation_challenge.py, row_aware_analysis.py,
cross_matrix_svd.py, bilinear_vs_gated.py, predictive_rewiring.py,
weight_only_predictor.py
**What we learned:** D_k (Gram-operator invariants) are insufficient for
composition — valid negative (entry 103). But there is no deeper weight-only
compositional invariant hiding in the gate-up coupling. Permutation damage
is predicted by the DU product. The gate's role is input-specific modulation,
not weight-level coupling. The "tensor composition" framing was overclaimed;
the correct framing is hidden-unit gauge symmetry.

---

## Mixed Moment Critical Exponent — 2026-09-18

**Central question:** Can pairwise spectral statistics (eigenspectrum,
coherence) predict frame operator composition, or do mixed moments carry
essential information about eigenvector alignment?

### Synthetic proof (entry 97)

5 ensembles x {d=64-1024} x {gamma=2,4} x 30 trials. Power-law frame operators with alpha=0.8 (matching real models). Shared top-25% eigenvectors vs random. 6/6 pre-registered predictions confirmed.

**Key result:** D1 separates shared from random at z > 49 across all d. The separation GROWS as d^{0.575} (predicted d^{0.6}). Critical exponent alpha = 0.5: below it pairwise geometry suffices; above, mixed moments are essential. Real models (alpha=0.6-0.9) are in the "fails" regime.

### Real model verification (entry 98)

SmolLM2-135M (d=576) and Qwen3-0.6B (d=1024). Normalized D1_norm between gate_proj and up_proj frame operators at every layer.

**Key result:** D1_norm positive at ALL layers (0.05-1.32). Random baseline = 0. Sharing increases through depth, peaking at last layers (Qwen3 L27: 1.32, 10x early baseline). Invisible to per-component spectral analysis.

### D-scaling across SmolLM2 ladder (entry 100)

SmolLM2-135M (d=576), 360M (d=960), 1.7B (d=2048). Same architecture family, 3.5x range of dimensions.

**Key result:** D1_norm CONSTANT at ~0.21 across all dimensions. Training co-adapts alpha (spectral exponent decreases with d) to maintain constant cross-component coupling. Top-4 eigenvector overlap increases (0.35 -> 0.42) but per-vector contribution decreases (flatter spectra). Larger models distribute coupling more evenly across depth.

**Formal theorem:** theory/mixed_moment_critical_exponent.md
**Data:** experiments/results/frame_composition/
**NOTEBOOK entries:** 97-100
**What we learned:** Pairwise geometry is provably insufficient for trained networks. Mixed moments are the native cross-component information. A phase transition at alpha=0.5 separates two regimes. Real models maintain constant cross-component coupling (~0.21) by co-adapting spectral shape with dimension.

---

## Frame-Theoretic Analysis of Trained Transformers — 2026-09-18

**Central question:** Do trained transformer weight matrices approximate the tight frame / equiangular tight frame structure assumed by formal superposition theory? What mathematical structure do they have instead?

### Frame analysis (3 models)

Analyzed embedding and MLP weight matrices of SmolLM2-135M (d=576), Qwen3-0.6B (d=1024), and Phi-1.5 (d=2048) as overcomplete frames.

**Key finding:** Real models are 100x-10,000x from tight frame ideal. Condition numbers: 640-12,000 for embeddings, 180-25,888 for MLPs. Coherence 15-30x the Welch bound. The formal theory's assumptions are massively violated. Yet models achieve superposition.

### Eigenspectrum shape

Spectra follow power laws (exponent -0.35 to -0.90), NOT Marchenko-Pastur (random matrix) or uniform (tight frame). Tail exponents steepen through depth (-1.3 to -1.8). SmolLM2 embedding is effectively 4-dimensional (participation ratio 3.9/576). Gate_proj is steeper than up_proj universally.

### Eigenprojection test (H1b: tail vulnerability)

Perturbation vectors projected into gate_proj eigenbasis at 5 layers per model. High-sensitivity perturbations project LESS onto top eigenspaces at the input layer (SmolLM2 L0: rho=-0.43; Qwen3 L0: rho=-0.83, p=0.04). Interpretation: top eigenspaces are robust (high energy); tail eigenspaces are fragile. The power-law spectrum IS the vulnerability gradient. Late-layer patterns diverge across architectures (compensation strategies differ).

### Rate-distortion prediction and first-principles derivation (entries 95, 99, 101)

Monte Carlo test: random embedding directions with information-weighted norms produce FLAT spectra indistinguishable from uniform random. Power law requires directional structure from training. Phi-1.5 calibration falsifies monotone alpha(d); controlling variable is n/d (overcompleteness ratio), not d alone.

**First-principles confirmation:** Single-layer embedding trained with SGD on Zipfian tokens + cross-entropy produces power-law eigenspectra. Uniform tokens → flat spectrum. Power law exponent controlled by (Zipf s, n/d ratio). n/d=2 → exponent -2.39; n/d=128 → exponent -0.97. Zipf s=0 → flat (-0.25); s=1 → steep (-1.75).

Per-token eigenspace rank: SmolLM2 median 32/576 (5.6%), Qwen3 326/1024 (31.8%). Tokens are hierarchically clustered in eigenspace.

### Effective Zipf measurement and quantitative prediction (entry 107)

All three tokenizers show effective Zipf s ≈ 0.5 (not s = 1.0). BPE subword tokenization flattens the frequency distribution. 5×5 grid of toy models (s □ {0.3-0.7}, n/d □ {8-128}) quantifies the joint dependence. Prediction for Phi-1.5 (s=0.53, n/d=25): within 21%. High-n/d predictions fail because toy training (5000 steps) is insufficient for convergent organization.

Three-variable model: exponent = f(Zipf s, n/d, training convergence).

### Spectral-composition bridge (entry 110) — NEGATIVE

Tested whether training on Zipfian data jointly organizes spectral structure AND compositional gate-up pairing. Minimal model (n=1024, d=64, h=128, untied unembed), 5 seeds, 4 conditions (gated/frozen-embed/additive/uniform). Fable-reviewed pair-sensitive signed-product statistic with Bonferroni correction.

**Result:** Bridge hypothesis REJECTED (Bonferroni p=1.0). Spectral structure does not predict composition. SURPRISE: additive MLPs develop z=-7.79 spectral anti-pairing; gating disrupts this, explaining why gated MLPs are pairing-sensitive.

### Spectral sensitivity test (entry 115) — NEGATIVE

Zero-ablation of up_proj at each layer of SmolLM2-135M. Measure output divergence.

**Result:** Spectral exponent does NOT predict sensitivity (rho=+0.28, p=0.14). Sensitivity is U-shaped (L0 and L29 critical, middle redundant). Position dominates over spectral structure. The depth gradient is descriptive, not predictive of functional importance.

### Scale test and LN confound (entries 113-114)

SmolLM2-360M confirms up_proj steepening (rho=-0.862). Post-LN spectra still flatten with depth (rho=+0.45, p=0.01), resolving the layer norm confound. Steepening rate approximately scale-invariant (-0.162 vs -0.142 normalized).

### Hidden state spectra — complementary specialization (entry 113)

Forward pass of SmolLM2-135M on 677 tokens of real text. Hidden state covariance eigenspectrum at each layer.

**Result:** Hidden state spectra FLATTEN with depth (rho=+0.871, p<0.001). Weight spectra steepen (rho=-0.891). Anti-correlated. Rules out residual accumulation as the cause of weight steepening. Interpretation: complementary specialization — richer representations require more selective weights.

### Spectral depth gradient (entry 112)

Comprehensive depth profile across MLP and attention components. Both models. MLP gate/up Gram exponents, attention QK/OV effective ranks, gate-up pairing z-scores.

**Result:** MLP up_proj exponent steepens monotonically with depth: SmolLM2 rho=-0.891, Qwen3 rho=-0.649 (both p<0.001). Gate follows. Attention QK/OV effective ranks show NO depth trend. Creates a generalization-to-specialization gradient: early layers use many spectral directions (flat spectra), late layers concentrate on few (steep spectra). The pairing dipole (entry 111) sits at the extreme end. QK effective rank = 80% of d_head; OV = 93%.

### Real-model pairing verification (entry 111)

Computed signed-product pairing statistic across all 30 layers of SmolLM2-135M. 200 shuffles per layer, embedding eigenbasis. Pure weight analysis.

**Result:** Aggregate top-5 z = -0.11 (p=0.375, not significant). 28/30 layers show z ≈ 0 — confirms gating destroys anti-pairing in real models. ANOMALY: layer 28 (penultimate) shows POSITIVE pairing: top-5 z = +2.48, 137/576 positive-significant eigenvectors, max z = 11.5, Bonferroni p ≈ 1e-6. Suggests near-output layers develop spectral co-alignment from concentrated loss gradients.

**Data:** experiments/results/frame_analysis/real_model_pairing.json
**NOTEBOOK entries:** 88-101, 107, 110-115
**What we learned:** The theory-practice gap is RESOLVED for embeddings. Power law emerges from Zipfian data + gradient descent. The mechanism is directional structure (organized token-eigenspace alignment). The degree of organization depends on overcompleteness ratio n/d, not d alone. Effective Zipf s ≈ 0.5 for BPE tokenizers. Spectral structure and compositional pairing are INDEPENDENT — the additive anti-pairing discovery (entry 110) shows that gating decouples pairing from spectral constraints.

---

## HD Geometry Probes — 2026-09-18

High-dimensional geometry of transformer hidden states across layers.

Model: SmolLM2-1.7B (24 layers, d=2048). All probes: last-token extraction, fp32 CPU.

**Central question:** Do transformer representations exhibit native high-dimensional mathematical structure beyond standard R^n geometry?

### Probe 1: Arithmetic expressions (ARTIFACT)

- 100 arithmetic expressions (`x = a op b`), all sharing suffix `\nprint(x)\n# Output: `
- **ARTIFACT:** Shared suffix made all last tokens identical → cos=1.0 at L0
- Apparent "spread-then-concentrate" hunchback was context propagation artifact
- **Status:** Invalidated. Confirmed by Probes 2-3 which showed no hunchback.

### Probe 2: Diverse inputs (clean)

- 150 inputs: 50 arithmetic, 50 natural language, 50 code (bare text, no shared suffix)
- **NO hunchback** for any class or combined. All trajectories monotonically concentrate.
- Cross-class convergence zone at L12-L20 (~0.52-0.65), then L24 separates domains
- Arith-code stay close (0.70); NL splits from both (0.35-0.37)
- Per-class final cosine: arith 0.956, NL 0.806, code 0.824

### Probe 3: Controlled similarity threshold (clean)

- 120 inputs: 4 sets × 30 (identical_prefix, paraphrases, same_domain, cross_domain)
- **NO hunchback** for ANY input set. All monotonically concentrate.
- Final cosine preserves input similarity ordering (identical_prefix 0.871 > cross_domain 0.764)
- Differentiation threshold hypothesis not supported

### What survived Fable + Droid dual review

1. Cross-domain mid-layer convergence → final-layer separation (real but not novel)
2. Context-propagation mechanism (identical last token → hunchback) is concrete finding
3. Per-class final cosine reflects next-token distribution similarity
4. **All patterns are known phenomenology using standard R^n tools** — not breakthrough level

### What was learned

- ID hunchback, anisotropy, trajectory geometry are well-studied (5+ papers cited by reviewers)
- Input cosine ≠ feature superposition (category error corrected)
- eff_dim bounded by sample size n (rank ceiling), not d
- cos_mean = (n||ȳ||² - 1)/(n-1) — the "dissociation" is elementary

## MP-Deviation & Interference Composition — 2026-09-18

Zero-cost reanalysis of 7-model balanced kill data (69 cells × 24 perturbations).

### MP-Deviation Analysis (KILLED)

Tested whether eigenvalue spikes above Tracy-Widom threshold in behavioral Gram

matrices predict transfer hierarchy. Recommended by Fable strategic review R2.

- All 7 models: 1-3 spikes above TW (MP deviations exist)
- Spike overlap does NOT predict held-out transfer (rho near 0, all splits)
- Spike count ~ gap correlation: split-dependent artifact (p=0.034 interleaved → p=0.562 full)
- MP framework adds no predictive power over standard PCA

- **Kill criterion #2 triggered:** deviations exist but don't predict

### Interference Composition / Transitivity (KILLED)

Tested whether perturbation correlations follow product rule r(i,k) ~ r(i,j)*r(j,k).

Deviations would indicate a composition law.

- Raw: positive residual +0.13 to +0.20 (all 7 models) — apparent superadditivity
- 3-factor PCA captures 79-97% variance
- After factoring: residual flips to -0.02 to -0.12 — superadditivity ENTIRELY from shared factors
- Factors are architecture-family-specific (Qwen3-StableLM cluster; SmolLM2 cluster)
- **Kill criterion triggered:** composition explained by ~3 trivial factors

### Behavioral Rank Bootstrap (POSITIVE)

Bootstrap test: is behavioral rank model-intrinsic or perturbation-set-dependent?

Zero-cost reanalysis of balanced kill data.

- Behavioral rank IS model-intrinsic (matches synthetic rank-k, NOT random)
- Rank varies 1 (SmolLM2-360M) to 4+ (SmolLM2-1.7B-Instruct)
- PR predicts k80 perfectly: rho=0.954, p=0.001
- Instruction tuning doubles PR (1.32→2.62)

### Weight Spectral Bridge (KILLED)

Tests whether weight matrix spectral properties predict behavioral PR. CPU only.

- No weight spectral quantity predicts behavioral PR (all p>0.25)
- **Decisive:** SmolLM2 base/instruct have identical weight spectra (PR delta 0.1%)

but 98% different behavioral PR

- Weight spectra encode capacity, not behavioral routing

### Jacobian Derivation (KILLED — Fable R4)

Theory-first: derive sensitivity hierarchy from attention Jacobian. Value/routing

channel decomposition, causal masking argument.

- Value/routing dichotomy stated backwards (both zero at t<p, both nonzero at T)
- Perturbations not in Jacobian domain (variable length changes)
- d_add_zero falsification: appends "+0" (zero original positions touched), should

behave A-like under theory. FAILS in 6/7 models (rho vs A = 0.06-0.86 vs AA 0.64-0.94)

- Not novel: QK/OV circuit split (Elhage 2021) + adversarial Jacobian (Goodfellow 2015)
- R3 kill criteria: 3/4 met. See scratchpad/fable_jacobian_r4.md

### Attention Routing Diversity (KILLED)

Tests whether base vs instruct routing diversity explains behavioral rank difference.

CPU, ~50 forward passes per model on SmolLM2-1.7B base/instruct.

- Routing nearly identical (delta <2% in heads changed, <1% in Jaccard)
- 50-97% of heads change for every perturbation (not sparse)
- Routing change is positional (token insertion), not content-based
- Behavioral rank 2× difference does NOT come from routing diversity

### Cumulative assessment

Behavioral data (69×24) is intrinsically rank-3. All structure reduces to 3 architecture-

family-specific vulnerability factors. RMT, interference composition, transitivity,

weight spectra, Jacobian theory, and routing diversity add nothing beyond PCA.

Dataset is exhausted for high-d analysis.

**HD Math direction KILLED** (Fable R3 criterion #1 triggered):
3 theory-first cycles (concentration/routing, weight spectral bridge, Jacobian),
0 surviving testable predictions. One salvage finding: d_add_zero dissociates
positional from computational accounts of the hierarchy.

## TRHO Transfer Rho Spectrum — 2026-09-17

Behavioral transfer rho across language model architectures, training strategies, and perturbation types.
2 model families, 9 configurations, 40-50 cells per experiment.

**Central question:** Is low behavioral transfer (rho) a universal property of language models,
and does it vary with perturbation type?

### Key Findings

1. **Transfer hierarchy established:**
- Within-surface rho: 0.63-0.72 (trivial perturbations are self-consistent)
- Cross-type rho: 0.08-0.36 (surface cannot predict semantic; Qwen p=0.13 NOT significant)
- Within-semantic rho: 0.14-0.29 (structural changes unpredictable)

2. **Effective dimensionality (model-independent):**
- Surface perturbations: ~1.9 effective dimensions
- Semantic perturbations: ~4.1 effective dimensions
- Ratio: 2.2x in BOTH Qwen3 and SmolLM2
- Semantic PC1 captured by surface (74-93%), but PC3/PC4 nearly orthogonal (2-4%)

3. **1/sqrt(d_eff) bound:**
- Matches surface rho within 2% (predicted 0.731, observed 0.718)
- Overshoots semantic by 3.7x (predicted 0.497, observed 0.135)
- Excess non-transfer: semantic perturbations have adversarial structure beyond dimensionality

4. **Perturbation correlation confirms hierarchy:**
- Surface correlations: 0.48-0.65 (perturbations probe same subspace)
- Semantic correlations: 0.18-0.25 (each perturbation probes different pathway)
- Commutative reorderings (a+b vs b+a) produce non-zero TV: refutes complexity confound

5. **Bootstrap CIs (500 iterations):**
- Qwen cross-type: [-0.031, 0.341] — includes zero, cannot reject null
- SmolLM2 cross-type: [0.185, 0.709] — excludes zero
- All within-surface CIs exclude zero

6. **Readout dependence:**
- 11-bin (task-specific): rho 0.13-0.30
- Full-logit cosine (full behavioral state): rho 0.25-0.68
- Phi-1.5 full-logit ERASES the semantic gap entirely (surface 0.70, semantic 0.66)
- Task-specific information transfers worst

7. **Biology >> LLM:** Protein/yeast rho 0.88-0.98 vs LLM semantic 0.14-0.29.

8. **Noise calibration clean:** Deterministic TV=0.0, permutation p<0.001, 4.9σ above null.

9. **Perturbation transfer matrix (full-logit):**
- Qwen: semantic block mean rho=0.361, worst pair varname_y<->assign_twice at 0.044
- SmolLM2: semantic block mean rho=0.613 (intermediate)

- Phi-1.5: semantic block mean rho=0.754 (explains gap erasure: high within-semantic correlation)
- No negative correlations in full-logit; 11-bin negatives were readout artifacts
- func_call universally lowest-correlated semantic perturbation across all models

10. **NL math transfer rho (Qwen3-1.7B-Base):**
- ALL rho values collapse vs code. 11-bin surface: 0.518 (vs 0.685 code), semantic: 0.094 (vs 0.309)
- NL "surface" perturbations are high-dimensional (3.81 vs 1.62): every word is semantic
- Dimensionality ratio shrinks (1.44x NL vs 1.99x code) because NL surface is also high-dim
- Implication: code alignment is partially certifiable (trivial perturbation class exists);
NL alignment is uncertifiable (no trivial perturbation class in NL)

11. **Common-factor null (fragility control — CORRECTED):**
- Per-cell fragility accounts for most of raw rho (within-cell null means 0.48-0.87)
- ORIGINAL "semantic collapses" claim RETRACTED — was covariate contamination artifact
- Clean partial (other-type covariate): Qwen FL surface 0.76, semantic 0.43 (gap persists)
- Semantic retains condition-specific structure in ALL models (clean partial 0.42-0.77)
- SmolLM2 FL surface is ENTIRELY fragility (within-cell null p=0.26)

12. **NL multi-model comparison (SmolLM2, Phi-1.5, full-logit):**
- Phi-1.5 gap erasure is CODE-SPECIFIC: ratio 1.05x (code) -> 1.82x (NL)
- SmolLM2 is DOMAIN-STABLE: ratio 1.49x (code) -> 1.50x (NL)
- Qwen3 COLLAPSES in NL: surface 0.661->0.175, semantic 0.227->0.048
- Model ordering reverses in NL: SmolLM2 > Phi-1.5 > Qwen3
- CAUTION: Phi-1.5 P(digit)=0.001 in NL; 11-bin unreliable, full-logit valid

13. **Improved theoretical bound (mac/sqrt(d_eff)):**
- mac = mean absolute pairwise correlation between perturbation effects
- mac/sqrt(d_eff) has mean error 6.7% vs 15.6% for 1/sqrt(d_eff) alone
- For Qwen3 semantic: 11% error (mac/sqrt) vs 146% error (1/sqrt)
- All predictors rank-order models correctly (n=6 too small to discriminate)

14. **Paired-gap bootstrap (direct CI on surface−semantic):**
- Qwen FL: gap +0.241 [+0.084, +0.430] — EXCLUDES ZERO (P(gap>0)=0.998)
- Qwen 11-bin: gap +0.147 [-0.030, +0.330] — includes zero
- SmolLM2 FL: gap +0.046 [-0.144, +0.212] — includes zero
- SmolLM2 11-bin: gap +0.173 [+0.028, +0.373] — EXCLUDES ZERO
- Phi FL: gap +0.002 [-0.095, +0.107] — no gap (50/50)
- Headline: Qwen full-logit gap is statistically established

15. **Disattenuated cross-type correlation:**
- Qwen FL: cross=0.367 vs predicted=0.387 (one factor fits, disatt_r=0.948)
- All others: one factor rejected (disatt_r=0.35-0.76)
- 4/5 model×readout combos reject the single-factor model
- Qwen FL is the exception: surface and semantic fragility rankings coincide

16. **Held-out perturbation prediction:**
- LOO within original 12: surface rho=0.76, semantic rho=0.51 (fragility predicts within-family)
- Cross-type: surface fragility → semantic held-out: rho 0.30-0.53
- Novel perturbations (dead_code, redundant_parens, int_str_roundtrip): ALL rho ≈ 0 (p>0.4)
- Fragility is perturbation-family-specific, NOT a universal cell property

17. **Cross-domain fragility decomposition (NL vs code):**
- Fragility loading is MODEL x DOMAIN specific — same model allocates it differently
- Qwen3 CODE: fragility dominates both surface (R2=88%) and semantic (R2=83%)
- Qwen3 NL: surface is fragility-INDEPENDENT (R2=0.6%!), semantic is 92% fragility
- SmolLM2 CODE: surface is 94% fragility, semantic only 30% fragility
- SmolLM2 NL: both are 80-90% fragility, both collapse to ~0 after removal
- KEY: Qwen3 partial gap is CONSERVED: +0.255 (code) vs +0.256 (NL)
- The gap is an architectural invariant across domains despite completely different fragility allocation
- SmolLM2 code retains genuine semantic structure (partial rho=0.377) but SmolLM2 NL does not

18. **StableLM-2-1.6B (4th architecture family, PARTIAL):**
- Code full-logit: surf=0.918, cross=0.763, sem=0.827 (ratio 0.97x, NO GAP)
- Code 11-bin: surf=0.735, cross=0.419, sem=0.406 (ratio 1.36x)
- NL full-logit: surf=0.640, cross=0.443, sem=0.206 (ratio 1.91x, HUGE gap)
- NL 11-bin: surf=0.612, cross=0.091, sem=0.025 (ratio 1.55x)
- Same pattern as Phi-1.5: code gap erasure + NL gap massive
- Falcon-H1-1.5B (hybrid SSM-attention) still running

19. **Dimensionality scaling with perturbation vocabulary:**
- Qwen: d_eff = 0.253*n + 0.28, R2=0.976 — LINEAR growth, no saturation
- d_eff/n constant (0.26-0.29): each perturbation adds ~0.25 new dimensions
- SmolLM2: d_eff/n decreases from 0.23 to 0.18 — SATURATING
- Qwen rho DECREASES as vocabulary grows (0.87 -> 0.63); SmolLM2 INCREASES (0.87 -> 0.92)
- Model-dependent sensitivity landscape compactness predicts cross-type transfer

20. **Cross-model fragility transfer (zero-cost):**
- Code: Qwen3 <-> SmolLM2 fragility rho=0.243 (p=0.13, NOT SIGNIFICANT)
- NL: Qwen3 <-> SmolLM2 fragility rho=-0.055 (p=0.74, ZERO)
- Cross-domain: Qwen3 code<->NL rho=0.163 (NS); SmolLM2 rho=0.416 (p=0.008)
- Fragility is (model x domain x perturbation-family)-specific, maximally non-transferable
- Different models find different cells sensitive on the SAME 40 arithmetic problems

21. **Fable R13 review — claim triage:**
- WITHDRAWN: "Qwen3 collapses in NL" (fp16 floor), "SmolLM2 domain-stable" (fragility-dependent),
"Phi gap erasure code-specific" (precision mismatch), mac/sqrt(d_eff) (in-sample, fails holdout),
"no negative correlations in full-logit" (false in NL), biology >> LLM (no backing data),
d_eff as independent finding (restatement of correlation)
- SURVIVES: "Per-input behavioral sensitivity is a perturbation x input interaction,
not an input property." Surface class transfers because its 6 members are ONE perturbation
in 6 spellings (d_eff ~ 1.9). Everything else doesn't transfer.
- POSITION CONFOUND identified: surface appends AFTER assignment; semantic rewrites the assignment.
Class is confounded with "touches the line the answer depends on."
- KILL EXPERIMENT designed: 4 groups x 6 perts, fp32, CPU. Resolves fp16, position, held-out.

22. **R13 kill experiment (COMPLETED — DECISIVE):**
- Qwen3-1.7B, fp32 CPU, 40 cells x 24 perturbations x 2 surfaces, 352s
- (a) 6 original inert appends after assignment
- (b) 6 NEW inert appends after assignment (held-out test)
- (c) 6 inert insertions BEFORE assignment (position control)

- (d) 6 meaning-preserving REWRITES of the assignment (matched position)
- **Results (full-logit Spearman rho):**
- a<->a = 0.785: within original inerts (baseline)
- a<->b = 0.811: held-out inerts TRANSFER (R13's "near-duplicates" prediction REFUTED)
- a<->c = 0.611: position control WORKS — before/after gap is ~0.2, not the whole story
- a<->d = 0.333: GAP IS REAL — rewrites don't transfer to inerts even at same position
- d<->d = 0.224: rewrites barely transfer to EACH OTHER
- **Results (11-bin):** same gradient: a<->b=0.746, a<->c=0.565, a<->d=0.328, d<->d=0.182
- **Gradient:** same-type inerts (0.81) > cross-position inerts (0.61) > cross-type (0.33) > within-rewrite (0.22)
- **Three confounds resolved:** (1) held-out test PASSES — surface class is real, not 6 near-duplicates;
(2) position contributes ~0.2 but doesn't explain the full gap; (3) fp32 consistent with 11-bin (no floor issue)
- Key: the factor is whether the perturbation TOUCHES THE COMPUTATION PATH, not position
- R14 REVIEW (PARTIAL CONFIRM): gradient real but "computation path" unfalsifiable; position ~35%
of gap; a<->b>a<->a is group-homogeneity noise; fp32 confirms 11-bin not fixes full-logit;
needs SmolLM2 replication + syntactic novelty + inert-at-assignment controls.

23. **Kill experiment — SmolLM2-1.7B replication (COMPLETED — GRADIENT REPLICATES):**
- Same 4 groups x 6 perts, fp32 CPU, 40 cells, 357s, 95% accuracy
- **Results (full-logit):** a<->a=0.864, a<->b=0.861, a<->c=0.672, a<->d=0.583, d<->d=0.443
- Same gradient: same-type > cross-position > cross-type > within-rewrite
- Gap COMPRESSED vs Qwen3 (0.28 vs 0.45) but structure preserved
- ZERO distances below 1e-3 — no fp16/fp32 floor concern
- SmolLM2 more uniform in perturbation sensitivity (consistent with "domain-stable")

24. **R14 control experiments (COMPLETED — SURFACES DISAGREE):**
- Groups: A (reference inert, 6), E (unusual inert appends, 6), F (inert assignment-line mods, 6), D (rewrites, 6)
- Qwen3-1.7B-Base, fp32 CPU, 40 cells × 24 perts × 2 surfaces, 366s, 100% accuracy
- **Full-logit ordering:** A(0.785) > E(0.645) > F(0.471) > D(0.224)
- **11-bin ordering:** A(0.686) > F(0.583) > E(0.442) > D(0.182)
- **E and F SWAP between surfaces** — two readouts disagree about which control group is "like A"
- Full-logit says: unusual appends transfer well (E≈A), assignment-line mods don't (F≈D)
→ assignment-line TOKEN CONTENT matters for representation-level sensitivity
- 11-bin says: assignment-line mods transfer well (F≈A), unusual appends don't (E≈D)
→ DISTRIBUTIONAL NOVELTY matters for decision-level sensitivity
- Both surfaces preserve the A > D gradient — the gap between inerts and rewrites is robust
- Cross-group: full-logit a<->e=0.609, a<->f=0.565; 11-bin a<->e=0.430, a<->f=0.572 (same swap)
- Distance magnitudes: E median slightly above A, F slightly above E, D highest (consistent gradient)
- **CALIBRATION (per-cell bootstrap):** E-F swap NOT significant on either surface
- fulllogit: E<->E minus F<->F = +0.171 CI [-0.013, 0.355] (includes 0)
- 11-bin: E<->E minus F<->F = -0.138 CI [-0.341, 0.048] (includes 0)
- Mann-Whitney A<->E vs A<->F: fulllogit p=0.79, 11-bin p=0.067
- Within-group heterogeneity dominates: f_semicolon (0.872 fl, 0.810 11b) > any E member;
e_list_pop (-0.021 11b) < any F member. Groups E/F not internally coherent.
- **Honest conclusion:** gradient from inerts to rewrites is robust across readout surfaces,
but the intermediate region cannot be cleanly attributed to either "computation path" or
"syntactic novelty". Individual perturbation identity dominates group membership.

- **Property analysis (18 non-A perturbations):**
- Position (after=0, at=1, replace=2) predicts FL rho: r=-0.538, p=0.021 uncorrected
R15: does NOT survive Bonferroni for 10 tests (5 predictors × 2 surfaces). SUGGESTIVE only.
- Mean distance predicts 11-bin rho: r=-0.703, p=0.001 (SURVIVES Bonferroni correction)
R15: but tautological — perturbations with larger distances have noisier rankings (rank-SNR)
- tokens_added, unusual, modifies_assign: all p > 0.1
- R15 CORRECTION: "two independent axes" downgraded to one confirmed but tautological predictor
(mean distance) plus one suggestive uncorrected predictor (position ordinal)

25. **Kill experiment — Phi-1.5 (COMPLETED — NO GRADIENT):**
- microsoft/phi-1_5, fp32 CPU, 40 cells × 24 perts × 2 surfaces, 306s, 92.5% accuracy
- **Full-logit:** a<->a=0.807, a<->b=0.739, a<->c=0.709, a<->d=0.752, d<->d=0.763
- **NO GRADIENT:** a<->d (0.752) ≈ a<->a (0.807), d<->d (0.763) ≈ a<->a. MWU p=0.52 (NS)
- Rewrites transfer to inerts AND to each other — Phi-1.5 is perturbation-robust
- 11-bin: compressed range 0.514-0.601, 84% of distances < 1e-3 (resolution floor)
- Confirms gap erasure from earlier spectrum study under controlled kill experiment design
- **MODEL-DEPENDENT gradient:** Qwen3 (strong), SmolLM2 (compressed), Phi-1.5 (absent)
- R15 CONDITIONAL: result depends on P(digit) verification. If P(digit)≈0.001, 11-bin is noise
and full-logit measures non-arithmetic behavior. 84% of 11-bin distances < 1e-3 is consistent
with near-zero digit probability. MUST verify before claiming certifiability.
- R15: "code-specialized training" attribution confounded with arch/tokenizer/size (n=1)

26. **Perturbation dimensionality analysis (zero model runs):**
- PCA on perturbation correlation matrices across all kill experiments
- d_eff (participation ratio): Qwen3 kill 2.72/2.87, controls 3.55/3.59, SmolLM2 1.97/2.78
- PC1 = fragility (common factor), captures 49-70% of variance
- Groups barely separable: between/within distance ratio 1.07-1.50
- 5-8 PCs for 90% variance — perturbation space is ~5-8 dimensional in practice
- SmolLM2 most one-dimensional (d_eff=1.97 FL) = most fragility-dominated
- R15: d_eff is algebraic identity (participation ratio = n/(1+(n-1)·mean_r²)); confirms #19
dimensionality results in kill experiment context, NOT an independent finding (R13 withdrew this)

27. **Kill experiment — StableLM-2-1.6B (4th architecture, COMPLETED — GRADIENT PRESENT):**
- StableLM-2-1.6B (general, 1.6B), fp32 CPU, 40 expression cells x 24 perts x 2 surfaces
- Full-logit: a<->a=0.927, a<->b=0.937, a<->c=0.587, a<->d=0.628, d<->d=0.566
- Gap = 0.299 (MWU p=4.5e-13) — moderate gradient, between SmolLM2 and Qwen3
- Highest a<->a (0.927) and a<->b (0.937) of all 4 models — strongest inert transfer
- 82.5% accuracy (lowest of the 4; 7 cells wrong)
- Confirms: general-purpose models show gradient; magnitude varies by architecture

28. **Rewrite Interchangeability Index (RII, zero model runs; R15 REVIEWED):**
- RII = mean within-group-D Spearman correlation across cells
- Measures whether a model treats meaning-preserving rewrites as INTERCHANGEABLE
- Phi-1.5: RII=0.763, StableLM-2: RII=0.566, SmolLM2: RII=0.443, Qwen3: RII=0.224
- RII vs gradient: Pearson r=-0.952 (p=0.048) among 4 comparable models (1.3-1.7B, >80% acc)
- Cross-model perturbation rank: Qwen3 is outlier (r~0 with SmolLM2); others cluster at r~0.5
- R15 CORRECTION: "code-specialized → high RII" was OVERREACH (n=1, confounded)
- RII is a descriptive index correlating with gradient; causal driver unknown

29. **Kill experiment — CodeGen-350M-mono (5th architecture, COMPLETED — GRADIENT PRESENT):**
- CodeGen-350M-mono (code-specialized, 350M), fp32 CPU, 40 cells x 24 perts x 2 surfaces
- Full-logit: a<->a=0.762, a<->b=0.731, a<->c=0.354, a<->d=0.444, d<->d=0.368
- Gap = 0.318 (MWU p=2.3e-7) — REFUTES "code-specialized → no gradient"
- RII = 0.368 — REFUTES "code-specialized → high RII"
- Accuracy: 32.5% (barely above chance) — MAJOR CONFOUND with task incompetence
- 11-bin DEAD: 100% distances < 1e-3 (model puts near-zero probability on digits)
- Not directly comparable to 1.3-1.7B models due to scale × accuracy confound
- Interpretations: (a) code-specialization needs scale to produce certifiability,
(b) accuracy/task-competence is the real predictor, or (c) Phi's no-gradient is
architecture-specific (parallel attention), not training-domain-specific

30. **RII decomposition and P(digit) verification (zero model runs, 2026-09-18):**
- P(digit) verified from 11-bin distance magnitudes (no model loading needed):
Qwen3 (median 0.015, 0% < 1e-3), SmolLM2 (0.094, 0%), StableLM (0.089, 0%),
Phi-1.5 (0.0003, 83%), CodeGen (0.00001, 100%). Clean binary split: 3 digit-predicting,
2 code-continuation. 11-bin INVALIDATED for Phi/CodeGen; full-logit valid for all
- **RETRACTED (R16 R2): z-RII and FDI are null artifacts.** Row-centering k=6 D columns
gives expected pairwise Spearman = -1/(k-1) = -0.20; pure-noise matrices give -0.192±0.002;
the five models give -0.174 to -0.191. "Universal z-RII ≈ -0.18" IS the null, not a finding.
FDI = RII - z_RII = RII + 0.18 (constant shift), so FDI vs gap r=-0.952 is the existing
RII vs gap r=-0.944 relabeled. All z-RII/FDI claims withdrawn
- **REPLACEMENT (R16 E-corrected, NOW WITH CIs):** Fragility-partialled group rhos (rank
regression on per-cell mean distance): residual RII collapses near zero for all models
(CIs all include 0). RII variation IS largely fragility share. But the GAP survives
partialling with bootstrap 95% CIs (1000 resamples, all exclude 0 except Phi):
Qwen3 0.294 [0.099, 0.454], CodeGen 0.251 [0.106, 0.412], StableLM 0.633 [0.303, 0.803],
SmolLM2 0.274 [0.060, 0.516]. Phi 0.044 [-0.057, 0.150] includes 0 (NS).
The gradient is NOT a fragility artifact; it is real perturbation-type-specific structure
- **PERMUTATION NULL (independent test):** Shuffle perturbation labels within each cell (500
perms). Qwen3 Z=8.8, SmolLM2 Z=6.0, StableLM Z=6.2, CodeGen Z=5.5 (all p<0.001).
Phi Z=1.0 (p=0.168, NS). Perturbation identity matters beyond fragility for 4/5 models.
Permutation 95th percentile ≈ 0.08-0.10 for all models
- **CELL-EXCLUSION (Phi):** Leave-1-out gap [0.048, 0.064]; leave-3-out (500 samples) max
0.076 (none > 0.10). Phi's no-gradient is robust to cell exclusion

### Fable R15 adversarial review (2026-09-18):

- 7 weaknesses identified; key corrections applied to STATE.md
- CONFIRMED: multi-model gradient replication (now 4/5 models), Phi no-gradient
- OVERREACH: "code-specialized → certifiable" (n=1 confounded; CodeGen REFUTES simplest version)
- OVERREACH: "two independent axes" (position ordinal p=0.021 fails Bonferroni at 10 tests)
- RESTATEMENT: d_eff finding confirms #19, not independent
- Review: experiments/results/fable_strategy_r15.md

31. **RETRACTED: Copy-vs-compute control (R17 — cell-schema mismatch, 2026-09-18):**
- `copy_vs_compute.py` used the 20-cell `make_cells()` schema from `run_transfer_spectrum.py`,
but kill experiment JSONs use 40-cell arithmetic-expression cells (zero literal-copy cells).

The "simple/complex" split was an arbitrary answer-digit partition, not computation type.
Cell descriptions in STATE.md were factually false. Additionally, the 12-cell gap sits within
the random-12 null distribution (48th-88th percentile), and the MWU tested amplitude difference
not the rho gap. All claims WITHDRAWN. Process violation: entered STATE.md without review

32. **Per-perturbation distance profiles — DOWNGRADED to descriptive (R17, 2026-09-18):**
- "Qwen3 outlier" contrast NS at n=24 (Fisher z=1.66, p=0.10). Cluster is group-level effect
- Two most "model-dependent" perturbations (c_newline_before, a_whitespace) are tokenizer-confounded:
Qwen3's tokenizer merges them differently from other models
- d_temp_var is length-confounded (only D pert that adds a line)
- After group-demeaning, Qwen3-StableLM rises to r=0.62 (p=0.001); "cluster" collapses to NS
- Gradient survives exclusion of tokenizer-sensitive perturbations (all five models unchanged)
- Amplitude ordering model-dependent (Qwen3 D>A p=2e-9; others D<A all p<0.01) but gap is
rank-based (amplitude-invariant by construction); not an anomaly, a clarification

33. **Cell exclusion robustness, symmetric (R17 correction, 2026-09-18):**
- Phi exhaustive L3O: max gap 0.077 (cells 6, 26, 30) across all 9880 combinations
- Gradient models L3O (2000 random triples, R17): min gap Qwen3 0.387, SmolLM2 0.232,
StableLM 0.238, CodeGen 0.255. Gradient never collapses under any cell exclusion
- L3O 2.5th percentiles: Qwen3 0.41, SmolLM2 0.25, StableLM 0.26, CodeGen 0.28

34. **Phi readout saturation — CONFIRMED as readout artifact (R16 Step 1 + R18 restructure):**
- Removing ONE trailing space from query (`# Output: ` → `# Output:`) flips Phi from code
continuation (P(digit)=0.001) to digit prediction. Tokenizer: Q0→space token→newline, Q1→colon→digit
- **PRIMARY (40-cell kill-matched, same cells as other 4 models):** gap=0.217 [0.123, 0.355],
p=5.26e-11. P(digit)=0.980, accuracy=95%. Pre-registered gates PASS. Q0 control: gap=0.055.
- **SUPPLEMENTARY (20-cell, different cells/surfaces — NOT comparable to kill):** gap=0.335
[0.141, 0.494], p=8.76e-9. P(digit)=0.843, accuracy=85%. Larger gap partly confounded by
combined cell/surface/query changes (R18). RII under Q1: 0.235 [0.051, 0.412]
- Raw gap: Qwen3 (0.452) > CodeGen (0.318) > StableLM (0.299) > SmolLM2 (0.281) > Phi-Q1 (0.217)
- **STATUS: 5/5 CONFIRMED (R18 definitive test).** Phi Q1 passes ALL gates:
Z=4.6 (p<0.001), residual gap 0.386 [0.171, 0.564] excl 0, PC1 share 84.6%.
Residual gap is SECOND HIGHEST (above Qwen3/CodeGen). All 5 models confirmed.
- Qwen3 Q1 control: Q1 INADMISSIBLE on Qwen3 (P(digit)=0.019). Readout effect model-specific

35. **Bootstrap CIs + permutation null on fragility-partialled quantities (R16 Step 0):**
- 1000 bootstrap resamples, rank regression partialling on Q0 kill data
- **Raw gap CIs:** Qwen3 [+0.315, +0.593], CodeGen [+0.202, +0.436], StableLM [+0.191, +0.438],
SmolLM2 [+0.197, +0.385] — all excl 0. Phi Q0 [+0.005, +0.106] barely excl 0.
- **Residual gap CIs:** Qwen3 +0.230 [+0.077, +0.430], CodeGen +0.277 [+0.100, +0.421],
StableLM +0.560 [+0.256, +0.750], SmolLM2 +0.310 [+0.091, +0.533] — all excl 0.
Phi Q0 +0.005 [-0.076, +0.110] includes 0 (NS).
- **Residual RII CIs:** Qwen3 +0.062 [-0.037, +0.142], SmolLM2 +0.051 [-0.046, +0.164],
StableLM +0.061 [-0.027, +0.218], CodeGen +0.078 [-0.025, +0.197] — all include 0.
Phi +0.125 [+0.029, +0.263] — ONLY model with resid RII excl 0.
- **Permutation null for resid RII (500 shuffles):** Qwen3 bias-corrected +0.099 (significant),
SmolLM2 +0.071 (NS), StableLM +0.078 (NS), Phi +0.142 (significant), CodeGen +0.118 (significant)
- Confirms: gradient is real perturbation-type structure, not common-factor artifact

36. **TRANSFER RHO — RETRACTED "2/5 transfer" claim (R19 review, 2026-09-18):**
- Raw A→D correlation 0.56-0.92: real, driven by common fragility (all methods agree)
- Same-locus inert exchangeability: A→B residual 0.83-0.97, all 5 models (SOLID)
- **RETRACTED:** "2/5 models (Qwen3, StableLM) show type-specific transfer"
R19 found: StableLM flips sign under rank partialling (-0.42); outlier cell (10%2) drives it.
Qwen3 drops to 0.00 under rank+PC1+PC2; Simpson mixture across operator strata.
The 2/5 vs 3/5 split was COVARIATE COMPOSITION (C-PC1 vs B-PC1 controls the outcome).
a_empty in Group A means "inert sensitivity" IS baseline fragility (rho 0.87-0.99 with baseline).
- **All-PC1 anti-transfer also retracted** (suppression artifact, caught earlier)
- **NEW: Fragility has a second edit-locus dimension** (PC2, 8-17% variance).
After removing PC1+PC2: zero of five models shows residual A→D transfer.
- No model ordering is stable across methods (forking-paths hazard)
- Power 0.43 at rho=0.3, n=40 — cannot claim null or positive
- **Defensible:** fragility dominates; inert appends are exchangeable; no type-specific
transfer currently established for any model at n=40.
- Next: cell×perturbation interaction test (direct test), or ≥113-cell pre-registered run

37. **Tokenization-covariate regression (R17 Priority 2, zero cost, 2026-09-18):**
- Does tokenizer explain per-perturbation distance profile?
- Token-count delta between minimal/verbose surfaces is CONSTANT (4 tokens) across all 24
perturbations for 4/5 models (the only surface difference is `# Python code\n` prefix)
- Qwen3 has 1 exception: c_newline_before (3 tokens, tokenizer merge artifact)
- R^2: Qwen3 0.347 (below 0.5 threshold), all others 0.000 (degenerate — constant input)
- **VERDICT: Per-perturbation distance variation is NOT a tokenizer artifact.**
- The variation comes from how models process different perturbations, not from tokenization

38. **Operator-class test (R17 Priority 6, pre-registered, zero cost, 2026-09-18):**
- Pre-registered H1: D-sensitivity varies by operator class AND A-sensitivity does not
- Operators tested: +, -, *, %, // (** excluded, only 1 cell)
- **H1 FAILED for all 5 models.** Both A and D sensitivity vary by operator class:
Qwen3 (A p=0.003, D p=0.012), SmolLM2 (A p=0.000, D p=0.001),
StableLM (A p=0.002, D p=0.024), Phi (A p=0.000, D p=0.000),
CodeGen (A p=0.022, D p=0.319 — exception: D uniform)
- Operator class is a COMMON FRAGILITY axis, not D-specific
- "Pattern structure" is empty as a term — the sensitivity structure is just fragility
- Admissible under R17 rules (robustness check, not additive claim)

39. **RETRACTED: Row-permutation interaction test (2026-09-19, retracted same day by R20):**
- Row-permutation of 40x24 distance matrix is invariant for interaction SS (row means travel
with rows). All 20 p-values were floating-point artifacts (null_std ~ 1e-20). "5/5 additive",
"type-blind", "monolithic fragility" all withdrawn. See fable_strategy_r20.md.
- **Correctly specified test (R20, nested F + group-label perm, log scale):**
4/5 models show cell x group interaction (group-perm p: Qwen3=0.0003, SmolLM2=0.0007,
StableLM=0.0003, CodeGen=0.009, Phi=0.31 null). Cell x group share of residual: 0.26-0.40
vs 0.13 expected under H0.
- Within-group D coherence: rho 0.22-0.76. D is six unrelated probes, not a type.
- Process lesson: null_std ~ 1e-20 and p=1.000 across all conditions is a stop signal.

40. **Scale ladder — SmolLM2 (135M, 360M) + Qwen3-0.6B (2026-09-18):**
- Identical 40-cell, 24-pert kill experiment at smaller scales. fp32 CPU.
- SmolLM2-135M: gap=0.121 [0.065, 0.205], acc=52.5%, P(digit)=0.994, Perm Z=2.7 (p=0.004)
- SmolLM2-360M: gap=0.318 [0.207, 0.431], acc=90.0%, P(digit)=0.993, Perm Z=6.0 (p<0.001)
- Qwen3-0.6B: gap=0.489 [0.347, 0.628], acc=100%, P(digit)=1.000, Perm Z=8.8 (p<0.001)
- **NON-MONOTONIC SCALING:** SmolLM2 gap peaks at 360M (0.318), drops at 1.7B (0.281).
Qwen3-0.6B gap (0.489) EXCEEDS Qwen3-1.7B (0.452). Accuracy scales monotonically.
- **Gradient exists at 135M parameters** with only 52.5% accuracy — significant at p=0.004.
- RII: SmolLM2-135M=0.712 (D perturbations barely distinguishable), 360M=0.184 (differentiated),
1.7B=0.443. Qwen3-0.6B=0.169, 1.7B=0.224.
- **Qwen3-0.6B residual analysis:** residual gap 0.309 [0.115, 0.487], PC1=53.1% (LOWEST
fragility dominance of all models). ALL GATES PASS. Despite HIGHEST raw gap, residual gap
is middle-of-pack. Residual RII 0.015 [-0.061, 0.111] (near zero after fragility removal).
- **Confound:** Qwen3-0.6B uses `Qwen/Qwen3-0.6B` (instruct), 1.7B uses `Qwen3-1.7B-Base`.
Scale comparison confounded by instruction tuning. SmolLM2 ladder is clean (all same family).
- **PC1 ordering:** Qwen3-1.7B (51%) < Qwen3-0.6B (53%) << SmolLM2-135M (70%) < SmolLM2-1.7B
(78%) < SmolLM2-360M (91%). Lower PC1 = more complex sensitivity structure.

41. **Tukey non-additivity + multiplicative structure (2026-09-19):**
- Tukey 1-df: F=60-490 (p < 1e-13) all 5 models — data IS multiplicative on raw scale.
- Log transform reduces residual from 16-44% to 12-19%.
- Log-space permutation p > 0.39 — BUT this used the same broken row-permutation (R20).
The correctly specified group-label permutation finds 4/5 interaction (see finding 39).
- Variance decomposition (log): Cell 13-46%, Pert 37-75%, Residual 12-19%.
- The 12-19% log-space residual is REAL deterministic structure (fp32 CPU, no noise term).
- In 4/5 models it is organized by perturbation GROUP (cell x group share 0.26-0.40 vs 0.13 H0).

42. **Kill experiment — Qwen3-0.6B-Base (INSTRUCT CONFOUND RESOLVED, 2026-09-19):**
- Qwen/Qwen3-0.6B-Base, fp32 CPU, 40 cells x 24 perts x 2 surfaces, 314s, 100% accuracy
- P(digit) median = 0.996. Admissible readout (Q0).
- **Full-logit:** a<->a=0.910, a<->d=0.586, d<->d=0.394. Gap=0.087 [0.052, 0.129], Z=5.0
- **5.6x LOWER than instruct variant** (0.087 vs 0.489). LARGEST EFFECT IN THE PROGRAM.
- Same architecture, same tokenizer, same 40 cells — instruction tuning is the variable.
- Within-D coherence: 0.394 (Base) vs 0.169 (Instruct) — tuning destroys D-group structure
- parens<->int_cast: 0.729 (Base) vs 0.183 (Instruct) — NOT tokenization (same tokenizer)
- Cross-variant fragility rho = 0.333 (p=0.036) — weak, tuning reorganizes fragility
- Mean distance: 0.025 (Base) vs 0.019 (Instruct) — Base has LARGER distances but LOWER gap
- Residual gap: 0.241 [0.169, 0.307], PC1=87.8%. ALL GATES PASS. Residual > raw (2.8x)
same suppressor pattern as SmolLM2-360M (R21 caution at high PC1).
- **Qwen3 Base scale is MONOTONIC:** 0.6B (0.087) → 1.7B (0.452) = 5.2x increase.
Prior "non-monotonic" claim was artifact of comparing instruct (0.6B) vs Base (1.7B).
- **Implications for alignment:** Instruction tuning/RLHF creates massive surface sensitivity.
Base model treats perturbation types as nearly interchangeable (gap 0.087); post-training
creates a 5.6x gap. Fine-tuning is the problem, not the architecture.

### Status: Active — R21 CORRECTIONS APPLIED + INSTRUCT CONFOUND RESOLVED (2026-09-19).

GRADIENT: 8 models confirmed (gap 0.087-0.49, all Perm Z>=2.7). REAL. Exists at 135M params.

GRADIENT PERM Z: RESOLVED — within-row column shuffle, all Z>2 STAND.
Phi Q1 DEFINITIVE: gap=0.217, Z=4.6, residual gap 0.386 [0.171, 0.564] — ALL GATES PASS.
STRUCTURE: MULTIPLICATIVE dominant (first-order Taylor in small-angle regime, R21 derivation).
R2=1.000 RETRACTED. Correct log-space R2=0.82-0.88. CONTENT is in the 12-25% log residual.
INTERACTION: 7/8 models show cell x group interaction (nested F + group-label perm).
R21 CRITICAL: interaction EXISTS AMONG INERTS ALONE (AB vs C, p≤0.004 in 7/8).
Comment-vs-statement within A+B significant in 7/8. A vs B null in 8/8 (negative control).
Declared ABCD groups are NOT the axes models use to organize residuals.
ATTENUATION: A-D cross rho / sqrt(within-A * within-D) = 0.79-1.01. Single common cell
factor reproduces A-D gap. Inerts predict rewrites as well as other rewrites do (8/8).
"Not predictable from inert" WITHDRAWN; "less reliable" is supported.
WITHIN-D COHERENCE: rho 0.17-0.76. D perturbations don't agree on cell ordering.
D-COHERENCE OVERCLAIMS CORRECTED (R21): All rhos carry CIs (n=40). "Anti-correlated" →
uncorrelated. "Arithmetic identities" → cluster includes parens. "cond_true = control flow"
→ SmolLM2-1.7B only, driven by identity cells. Tokenization confound: parens/int_cast
share space-token deletion, are top-3 D pair in 5/8.
COPY CONTROL (Qwen3): Gap=0.403 [0.288, 0.516], Z=7.9. Expression gap=0.452.
H_surface PASS (diff=0.049): gradient persists on LITERAL assignments (x=5, no computation).
H_compute FAIL (ratio=0.89): gradient NOT driven by computation sensitivity.
LOCUS CONFOUND: 5/8 negative type effect. Interaction primarily POSITIONAL.
POSITION vs CONTENT (zero-cost, 7 models): Same-position/diff-content rho=0.705 vs
same-content/diff-position rho=0.530. Position wins 6/7 models (+0.175 mean).
Perturbations at the same position are MORE similar than same-content at different positions.
SAME-LINE LOCUS (zero-cost, 7 models): Same-line inerts +0.070 more D-correlated than
different-line inerts. 7/7 positive, 2/7 significant. Small but consistent.
DIRECTION STRUCTURE: 3/4 models perm-validated (Z=2.9-5.8) but residual is 12-25% of total.
NOT D-SPECIFIC: Groups A (Z=8-14) and B (Z=5-7) show STRONGER direction divergence than D.
Direction divergence is a general property of context modulation, not semantic-type-specific.
NOISE FLOOR: Qwen3 SNR=316x, SmolLM2-135M SNR=10,408x. Both CLEAN. 0% below noise.
D-GROUP CROSS-MODEL (8 models): Within-D rho 0.169-0.712. Cross-model consistency 0/28
significant. No D-perturbation consistently most anomalous. D-coherence does NOT predict
residual gap (rho=+0.05, p=0.91). Raw gap does NOT predict residual gap (rho=-0.11, p=0.80).
SCALE LADDER RESIDUALS: SmolLM2-360M residual (0.384) > raw (0.318) but R21 flags suppressor
artifact at PC1=90.5%. 135M fails (CI incl 0). Non-monotonic not significant (CIs overlap, n=3).
FABLE R21 ADVERSARIAL REVIEW (this session): 2/6 tautological, 2/6 underpowered, 1/6 inflated
framing, 1/6 real and damaging (locus confound). Corrections applied to STATE.md.
COPY CONTROL (4 models complete, 3 admissible):

| Model | Copy Gap | Expr Gap | Ratio | H_surface | Admissible |
|---|---|---|---|---|---|
| Qwen3-1.7B | 0.403 | 0.452 | 89% | PASS (0.049) | YES |
| SmolLM2-1.7B | 0.386 | 0.281 | 137% | PASS (0.105) | YES |
| StableLM-2-1.6B | 0.193 | 0.299 | 65% | PASS (0.106) | YES |
| CodeGen-350M | 0.241 | 0.318 | 76% | PASS (0.077) | NO (70% acc) |
| Phi-1.5 | 0.197 | 0.217 | 91% | PASS (0.020) | NO (P(digit)=0.001) |

ALL H_surface PASS, ALL H_compute FAIL. Ratio 65-137%. 3/3 admissible from 3 families.
2 inadmissible (CodeGen: low acc; Phi: low P(digit)) show same pattern.

Gradient is surface-driven, not computation-driven. SERIES COMPLETE.
INSTRUCT CONFOUND: RESOLVED. Qwen3-0.6B-Base gap=0.087 vs instruct 0.489 (5.6x).
Instruction tuning is the largest single effect. Qwen3 Base scale is monotonic.
Base within-D rho 0.394 vs instruct 0.169. parens<->int_cast 0.729 vs 0.183.
INSTRUCT POSITION EFFECT (Qwen3-0.6B base vs instruct, zero-cost):
Instruction tuning SELECTIVELY reshapes correlations:
A<->C (inert cross-position): 0.410 -> 0.503 (UP — learns inerts are "same kind")
A<->D (cross-type): 0.586 -> 0.301 (DOWN — becomes more type-discriminative)
D<->D: 0.394 -> 0.169 (DOWN — destroys rewrite coherence)
Gap: 0.324 -> 0.489 (UP — gradient AMPLIFIED)
Qwen3 IT amplifies gap 1.5x (like-for-like). BUT SmolLM2-1.7B-Instruct REPLICATION
FAILS: gap 0.281→0.251 (DECREASES). SmolLM2 IT uniformly amplifies all groups 2-2.8x
(no selective D reduction). Effect is ARCHITECTURE-DEPENDENT, not general.
MEANING-CHANGE TRANSFER (Group E, 2 models):
Qwen3-1.7B: D→E rho=0.536 (sig); Inert→E rho=0.261 (NS). D predicts, inert does not.
SmolLM2-1.7B REPLICATION: D→E rho=0.727 (sig); Inert→E rho=0.514 (sig). BOTH predict.
UNIVERSAL: D→E > Inert→E (Δ=0.213-0.275). D is ALWAYS the better predictor.
NOT UNIVERSAL: Whether inert alone predicts depends on model's A-D correlation baseline.
Per-pert: additive shifts (+1, -1) and reassignment transfer well; multiplicative/negation do not.
SPACE-TOKEN CONFOUND — DISMISSED (zero-cost, 7 models): R21 flagged parens/int_cast
share space-token deletion. Test: Jaccard of token-level edits vs D-pair behavioral rho.
Grand r=0.094, p=0.340. NULL. Control: add_zero/zero_plus Jaccard=1.0 but rho=0.023-0.777.
parens/int_cast coincidence, not causal. One exception: Qwen3-1.7B r=0.523 (p=0.045).
POSITION SHIFT MECHANISM (zero-cost, 7 models): Token-count similarity does NOT predict
C-group pair correlation. Grand r=0.010, p=0.918, n=105 pooled pairs. 5/7 models negative.
Prediction was: C pairs with same token-count shift should correlate more. FALSIFIED.
SmolLM2-1.7B highest C pair (rho=0.875) has LARGEST shift diff (4 tokens) — opposite.
Position organization is QUALITATIVE (before/after in causal attention window), not
QUANTITATIVE (how many tokens shift the position). Mechanism: before-perturbations enter
the assignment's attention context, after-perturbations don't.
OPEN: (1) DONE — Copy control complete (5/5). (2) Noise floor on remaining models.
(3) DONE — Space-token confound DISMISSED (grand r=0.094, NS).
(4) Locus-crossed design. (5) Instance replicates (k>=3).
(6) Nested F + group-label perm on Qwen3-0.6B-Base. (7) Base model for other families.
(8) DONE — IT replication on SmolLM2: FAILS (architecture-dependent).
(9) Design causal transfer test. (10) DONE — SmolLM2 meaning-change: D→E 0.727, Inert→E 0.514.
R24 CORRECTION: on non-identity cells (n=24), Inert→E drops to 0.143 (NS); D→E to 0.393
(borderline). Transfer driven by 2 of 6 D members (add_zero, cond_true). Token-prefix null.
(11) DONE — Header relocation (R22 E1) on Qwen3: gap halved (0.453→0.234). Header in middle
disrupts all correlations. ~50% header effect, ~50% genuine structural. C_C decreased (not
increased as adjacency predicted). D_D unchanged.
(12) Readout comparison: gap survives on 11-bin in all 4 models (0.19-0.37). But Qwen3
cell-profile cross-readout rho ≈ 0 — full-logit and 11-bin measure different cells.
(13) Balanced cell v3 on Qwen3: Gap=0.500, CI [0.411, 0.588].
(14) DONE — Balanced cell v3 on SmolLM2-1.7B: Gap=0.275, CI [0.202, 0.362], z=4.33.

DD < AD (0.531 < 0.669). Residual gap 0.389 (HIGHER than raw — operator strata absorb some gap). Replicates Qwen3 finding at lower magnitude.

(15) DONE — Prefix-form crossover on Qwen3 (2x2: add_zero/zero_plus x plus_one/one_plus). Diagonal mean rho 0.349, off-diagonal 0.063 (non-identity n=24). Partial prefix support: add_zero->plus_one=0.634 (strong, same prefix), add_zero->one_plus=-0.301 (anti, diff prefix). BUT zero_plus->plus_one=0.428 > zero_plus->one_plus=0.063 (breaks prefix prediction). E-E rho (plus_one vs one_plus) = -0.143: two E members are independent. Prefix form is partial mediator; add_zero is the dominant D member.

(16) DONE — Prefix-form crossover REPLICATION on SmolLM2-1.7B: signs replicate Qwen3. add_zero->plus_one=0.676, add_zero->one_plus=-0.405, zero_plus->plus_one=0.390, zero_plus->one_plus=-0.159. E-E rho: **-0.470 (p=0.021, SIG)**.

(17) DONE — Variance analysis (zero-cost): add_zero has 3.5-4.3x more variance than zero_plus. d_temp_var REVERSES column effect. Mean D -> E is NS in both models. Neither prefix nor gradient hypothesis survives D-level aggregation. Transfer is perturbation-member-specific, not group-specific. E-E anti-correlation is robust.

(18) DONE — 11-bin crossover reanalysis (Qwen3, 160 fwd passes, old 40 cells, 2026-09-19): E-E flips from -0.143 (NS) to +0.758 (p<0.001). ALL four entries positive on 11-bin. Off-diagonal > diagonal. Token-prefix null REFUTED on answer distribution. Gap reframed as D-diversity, not D-disconnection.

(19) DONE — 11-bin crossover replication (SmolLM2, 160 fwd passes, old 40 cells, 2026-09-19): E-E flips from -0.470 (p=0.021) to +0.124 (NS, p=0.563). Anti-correlation artifact CONFIRMED (sign flips in both models). BUT broad positive transfer is QWEN3-SPECIFIC: SmolLM2 has 1/4 significant vs 4/4. Only add_zero→plus_one survives in both.

(20) DONE — Fable R25 adversarial review (2026-09-19): DEVASTATING. 2×2 is a COLUMN main effect, not diagonal. `plus_one` transfers, `one_plus` doesn't. `one_plus` is a garden-path column (precedence confound on `* // %` cells). Operator strata REVERSE Qwen3 diagonal (within-stratum ad→plu = -0.23). SmolLM2 ad→plu survives within-operator (+0.52) but interaction collapses to 0.04. RETRACTIONS: "prefix form partial mediator" → downgrade; "E-E independence" → retract; "meaning change determines cells" → withdraw; "token-prefix sharing" → narrow to late-edit locality. Experiment was on old 40-cell set (violation of balanced-v3 mandate). PROPOSED EXPERIMENTS: (1) meaning-preserving late twins on balanced v3 + both readouts (the single most informative cheap test); (2) edit-position gradient; (3) `1+(e)` control; (4) rerun 2×2 on balanced v3 + 11-bin; (5) report four cells with CIs, not diag/offdiag.

(21) DONE — Within-operator stratum analysis (balanced v3, zero-cost, 2026-09-19): Gap SURVIVES and GROWS within operator strata. Qwen3: residual gap 0.515 > raw 0.500. SmolLM2: residual 0.365 > raw 0.275. DD < AD in 5/5 (Qwen3), 3/5 (SmolLM2) strata. d_add_zero and d_zero_plus have LOWEST AD correlations (0.068/-0.171 Qwen3) — the crossover's D members are the least representative. R25's operator-stratum attack applies to the crossover, not to the gap itself.

(22) DONE — Late-twin disambiguation (balanced v3, 6 perts, both readouts, 2026-09-19): D (e+0, e-0) vs E (e+1, e-1, e+2, e+3). All append-after-e. 828 fwd passes per model. **MEANING IS DEAD ON 11-BIN.** Replicated across Qwen3 and SmolLM2.

| | Qwen3 FL | Qwen3 11b | SmolLM2 FL | SmolLM2 11b |
|---|---|---|---|---|

| D-D - D-E | +0.234 [+0.082,+0.382] | -0.053 | +0.236 [+0.106,+0.357] | +0.015 [-0.171,+0.200] |

FL: meaning matters (CI excludes zero). 11-bin: meaning IRRELEVANT (CI spans zero).

E-E coherence structured by answer-shift direction (same-sign=0.836 vs opposite=0.725).

(23) DONE — Cross-position transfer (zero-cost reanalysis, balanced v3, 2026-09-19):

Reanalyzed existing kill data for A (after) vs C (before) position effects.

A-A > A-C in both models (CI excludes zero). A-D ~ C-D in both (rewrites equally low).

Position matters for after-perts, less so for before-perts (C-C < A-C in Qwen3).

(24) DONE — StableLM-2-1.6B late-twin disambiguation (3rd arch, 828 fwd passes, 2026-09-19):

EDIT LOCALITY ON BOTH READOUTS. FL: D-D-DE=-0.017 CI[-0.170,+0.129]. 11b: -0.044 CI[-0.201,+0.122].

Unlike Qwen3/SmolLM2, StableLM does NOT distinguish +/- in formatting geometry.

FL meaning distinction is MODEL-SPECIFIC. 11-bin edit locality now 3/3 models.

(25) DONE — Trivial pert inflation test (zero-cost, both models, 2026-09-19):

Dropping trivial A perts reduces gap by 10-12%. Gap robust to pert selection.

(26) DONE — Adversarial self-review (2026-09-19):

Strongest attack: D has 1 pair. "Fail to detect" not "meaning dead." Expand D planned.

(27) DONE — Expanded-D experiment (3 models, 6 D-D pairs each, 2026-09-19):

11-bin: 0/3 positive meaning. Qwen3 REVERSES (D-D-DE=-0.111, CI excl zero negative).

SmolLM2 +0.085 (CI spans zero), StableLM +0.062 (CI spans zero).

FL: SmolLM2 only clear (+0.180, CI excl zero). Qwen3 VANISHES. StableLM marginal.

Operator-family decomposition: within same family, meaning=+0.002/+0.008/-0.090 on 11-bin.

(28) DONE — Operator family decomposition (zero-cost, 2026-09-19):

All 3 models: ZERO within-family meaning effect on 11-bin. Family > meaning.

(29) DONE — SmolLM2-360M expanded-D (4th model, 2026-09-20):

FL: D-D-DE=-0.031 CI[-0.076,+0.009]. 11b: -0.035 CI[-0.097,+0.024]. BOTH REVERSED.

Supports operator-family confound critique: D-D dragged down by cross-family pairs.

(30) DONE — Adversarial review of expanded-D (Fable, 2026-09-20):

1 SOLID (FL=family-clustering), 2 QUALIFIED (meaning-dead, family>meaning), 1 FRAGILE

(expanded-D introduced family confound worse than 1-pair variance).

CRITICAL: D={+0,-0,*1,**1} spans 3 families. D-D is cross-family, D-E includes

same-family. Comparison structurally confounded. Fix: same-family D expansion.

(31) DONE → RETRACTED — Isomorphic same-family D (4 models, 2026-09-20):

D={+0,-0,+(0),-(0)}, E={+1,-1,+(1),-(1)}. Isomorphic sign×form. 552 fwd/model.

RETRACTED: DD-DE comparison confounded by answer identity (D→x, E→x±1).

Correct comparison (DD-EE): nothing significant. Answer identity test:

D-D <= E-E-same-sign in ALL 8 tests. Meaning has NO independent signal.

In arithmetic, meaning ≡ answer identity → cannot be separated.

(32) DONE — Answer identity confound analysis (zero-cost reanalysis, 2026-09-20):

Repartitioned all 28 pairwise correlations by answer identity (same/diff answer).

D-D ~ E-E-same-sign in SmolLM2-1.7B FL (+0.012 diff). REVERSE in 6/8 tests.

Dominant factor: sign matching (~0.18 gap), not meaning (~0.01 after control).

Meaning question CLOSED for arithmetic (meaning ≡ answer identity).

---

## OMT-0 Omega Modulus Transfer Test — 2026-09-15/17

Systematic empirical test of the omega modulus as a behavioral preservation predictor.

~30,000+ readouts across 65+ experiments on Qwen3 (0.6B/1.7B/4B), Pythia, StableLM, Gemma, GPT-2.

**Central question:** Can omega (modulus of continuity under behavioral distance)

trained on one set of conditions predict preservation under different conditions?

### Experiments (reverse chronological):

| # | Experiment | Readouts | Key Finding | |
|---|---|---|---|---|
| 81 | **Pre-registered identity prediction** | 72 | PRE-REGISTERED PREDICTIONS: 0/4 CORRECT. Two-factor model (meaningfulness x baseline) COMPLETELY FAILS on held-out pairs. var_echo: predicted amplify, actual 0.1x (baseline 0.136, much higher than expected). english_synonym: predicted suppress, actual 4.0x (meaningful words CAN amplify). code_return: predicted amplify, actual 1.5x. pragma: predicted amplify, actual 0.2x. CONCLUSION: identity amplification is NOT predictable from simple surface token features. The two-factor model overfit the training pairs. Omega's pair-dependence is an irreducible empirical quantity — must be MEASURED, not derived | |

| | | | | |
|---|---|---|---|---|
| 80 | **Surface type dissection** | 108 | THE MISSING FACTOR: Identity amplification depends on whether surface tokens are MEANINGFUL or ARBITRARY, not structural vs semantic. comment_short ("# a" vs "# b", arbitrary labels) has id=5.3x; comment_long ("# note here" vs "# info here", real words) has id=0.3x. SAME baselines (0.013 vs 0.011). Model's language predictions about real words compete with code-execution chain. Heavy shows opposite pattern: stmt_vs_stmt (8.3x) and cross_type (7.7x) are strongest — heavy wins when surfaces contain actual code. blank_vs_blank is INERT (0.4x for both). Clean rule: arbitrary-token surfaces let identity dominate; meaningful-token surfaces suppress it | |
| 79 | **Regime classifier (Fable E4)** | 144 | Three regimes are NOT a clean continuum. Spearman baseline vs id_amp: rho=-0.571, p=0.139 (not significant). CRITICAL: strong_explicit (most semantically assertive, "x is definitely 1") has identity SUPPRESSION (0.7x) and high baseline (0.025) — assertion strength ≠ regime. boundary (0.013 baseline) has 6.0x identity but comment_generic (0.019 baseline) has 0.3x — similar baselines, opposite identity effects. code_noise has heavy=5.4x (high). Heavy is qualitatively universal (always positive delta) but quantitatively varies 5.4x in delta_TV across pairs. Per-cell baselines vary up to 20x within a pair | |

| | | | | |
|---|---|---|---|---|
| 78 | **Throwaway variable boundary** | 204 | Cancellation on strong_assert tracks pure-underscore names: _ (0.48x), __ (0.53x), ___ (0.68x) all cancel; _0 (0.96x), _x (0.89x), tmp (0.90x), counter (1.04x) do NOT cancel. Boundary: pure-underscore = throwaway → cancellation; any alphanumeric = real → no cancellation. `result` outlier: 30.0x single amplification (highest ever for collision!) and 0.60x cancellation (moderate, possibly ceiling effect). On boundary_pair: ALL names accumulate (ratio > 1), no cancellation for any name. SEMANTIC: amplification depends on variable name's semantic relationship to output: result (30x) >> tmp/__ (14-15x) >> counter (8.5x) | |
| 77 | **Verbatim vs renamed repeat (Fable E3)** | 120 | Renaming `_` to `__` does NOT break double-collision dip (4.8x vs 5.4x verbatim), but `_x` DOES (13.5x). Cancellation is throwaway-variable redundancy recognition, not token-level copy suppression. double_mixed beats single (13.5x vs 11.2x). identity_plus_read (var=var + _=var) = 19.6x on strong_assert (highest ever). On boundary_pair: double_verbatim INCREASES (3.7x vs 2.8x single) — no cancellation, opposite of strong_assert | |

| | | | | |
|---|---|---|---|---|
| 76 | **Stacking grid on new pairs (Fable E1)** | 192 | Composition algebra CONFIRMED pair-conditioned across 4 pairs. identity ranges 13.5x (strong_assert) → 6.0x (boundary) → 1.3x (assert_weak) → 0.3x SUPPRESSION (comment_generic). ONLY 2 UNIVERSAL CONDITIONS: heavy (+) and identity+heavy (+). 13/15 conditions are MIXED sign across pairs. Pair correlation matrix: two weak clusters (sa+bp r=0.55, aw+cg r=0.38), near-zero cross-cluster. assert_weak has HIGH empty baseline (0.056) — most conditions suppress below it | |
| 75 | **Recency gate (Fable E2)** | 144 | Identity decays with distance on BOTH pairs. strong_assert: 13.5x → 10.1x → 4.5x → 2.5x (monotonic decay). boundary_pair: 6.0x → 3.6x → 3.1x → 4.2x (dips then RECOVERS). Heavy: OPPOSITE pattern — decays on strong_assert but GROWS on boundary_pair (2.7x → 8.1x). Per-cell: x_1 resistant to decay, y cells decay faster. Fable half-right: both pairs show decay, but different mechanisms (positional vs structural recovery). Heavy's value-mutation is amplified by intervening pass lines on boundary_pair | |
| 74 | **Collision repetition curve** | 120 | EVEN-ODD OSCILLATION: match collision 1=11.2x, 2=5.4x (DIP!), 3=12.3x (recovery!), 4=14.3x. Mismatch monotonic (no dip). At rep=2 mismatch overtakes match (6.0x vs 5.4x). Explains #73 double_collision self-cancel: even-phase destructive interference. Two matching copies pair-resolve ambiguity; three create new odd-man-out. Envelope grows: 4 reps = 14.3x | |

| | | | | |
|---|---|---|---|---|
| 73 | **Amplification stacking** | 192 | Stacking is REAL, non-commutative, heterogeneous. collision+isinstance=2.1x superadditive (strongest). collision→identity=2.0x but identity→collision=1.7x (order matters). double_collision=0.5x SELF-CANCELLING (destructive interference!). double_identity=1.2x. Most combos near-additive (0.8-1.1x). Collision stacks with everything except itself | |
| 72 | **Collision form generalization** | 96 | Value-mentioning forms (type(val), print(val), assert var==val) ALL amplify 8-11x. eval_var (_ = var) only 1.9x — variable read barely amplifies. assign_match strongest (11.2x). Category: value_mention (9.6x) >> var_reference (5.4x) >> control (2.9x). CRITICAL: identity (var=var, 13x) >> eval_var (_ = var, 1.9x) proves identity paradox is SELF-ASSIGNMENT (circular binding), not variable evaluation | |
| 71 | **Literal-value collision** | 168 | COLLISION CONFIRMED: value-matching `_ = val` amplifies 8.1x on strong_assert (vs 4.1x mismatch). Match+identity=28.1x (doubles identity's 13.2x). Match+heavy=27.2x. Two causal paths to same value create CONSTRUCTIVE interference via representational ambiguity. Per-cell range: 3.3x-11.8x (consistent). New amplification primitive alongside identity | |

| | | | | |
|---|---|---|---|---|
| 70 | **Depth gradient** | 144 | Pair-dependent depth scaling. On strong_assert: identity peaks at depth 3 (13.5x), non-monotonic. Heavy roughly monotonic (→11.6x). On boundary_pair: baseline TV grows with depth (0.005→0.046), drowning perturbation — identity=1.0x at depth 4. Scope-chain hypothesis PARTIALLY CONFIRMED: real effect visible only on well-controlled pairs. Measurement requires strongly-anchored surfaces | |
| 69 | **Pair vulnerability spectrum** | 120 | Anchoring hypothesis REFUTED. Vulnerability is COMPOSITION-SPECIFIC: assert_weak most absolutely vulnerable, comment_generic PROTECTS against identity+safety (27x lower TV than boundary) but vulnerable to heavy (6x). No pair is universally weak/strong. Margin gradient: assert_strong (0.55) > assert_weak (0.40) > boundary/comment (0.14-0.19) | |
| 68 | **Non-commutativity structure** | 432 | 6x6 composition matrix across 2 pairs. Empty is identity element (perfectly commutative). Mostly subadditive. Biggest asymmetry: nonvar→safety 3.54x. Only 1 superadditive pair. **KEY**: algebra is SURFACE-PAIR-DEPENDENT — identity→safety = 0.0118 (strong_assert) vs 0.1129 (boundary), a 9.6x difference. Same compositions, different pairs, dramatically different effects | |

| | | | | |
|---|---|---|---|---|
| 67 | **Error correction test** | 72 traj | **PREDICTIONS WRONG at step-40 (52.8%)** but **PARTIALLY RIGHT with robust scoring (66.7%)**. Step-40 TV contaminated by 2-step oscillation artifact (digit vs separator tokens). Robust metric: heavy/reassign correctly predicted to diverge (4/4 each). nonvar_42/safety_ comment correctly converge (4/4). empty incorrectly diverges (baseline instability). nonvar_expr incorrectly diverges (any token insertion destabilizes). Single-readout vs trajectory INVERSION confirmed but oscillation complicates interpretation | Heavy ALWAYS converges (0/4 predicted correctly) — mutation acts as attractor reset. Reassign ALWAYS converges (0/4). Empty mostly DIVERGES (3/4) — surface differences compound chaotically. **ACTUAL MECHANISM**: trajectory fate governed by DETERMINISTIC STATE ANCHORING, not mutation detection. Single-readout TV and trajectory fate are INVERSE: mutations converge trajectories (same attractor), no-ops diverge them (chaotic amplification) |
| 67z | **Variable access gradient (zero-compute)** | 0 | Exp #55 data reanalysis: clean monotonic gradient by variable interaction type. none/comment: 0% flips, margin=0.81-0.86. code-read (type_check): 11.1% flips, margin=0.59. noop-write (identity): 11.1%, margin=0.63. mutate (heavy): 22.2%, margin=0.39. Critical jump at comment→code-read boundary. type_check can CORRECT errors (9→correct_digit) | |
| 67y | **Composition algebra detail (zero-compute)** | 0 | Chain data: non-commutativity scales with strength difference (IN/NI=6.33x). ALL superadditive chains end with identity (TI=1.71x, OI=1.81x). Identity is universal amplifier, neutral is universal damper. INI sandwich = 2.7x superadditive. Identity self-composition peaks at length 2 (III < II) | |

| | | | | |
|---|---|---|---|---|
| 66a | **Bifurcation mechanism (zero-compute)** | 0 | TWO MECHANISMS found in #56 data. Type A: boundary_pair attractor capture at step 1 (surface_b locks onto 9-attractor). Type B: strong_assert error correction — step-4 spike resolves based on mutation semantics: heavy 4/4 diverge, nonvar_42 1/4 diverge, identity 3/4 diverge. Model performs AUTOREGRESSIVE ERROR CORRECTION | |
| 66b | **Composition algebra (zero-compute)** | 0 | #65 data reveals NON-COMMUTATIVE mostly SUBADDITIVE algebra. neutral→identity=0.0998 (1.77x superadditive, 4x stronger than reverse). Most compositions are subadditive (0.3-0.6x). Only "weak-then-strong" orderings create superadditivity. Weak perturbations PRIME for amplification by subsequent strong perturbations | |
| 60b | **Bifurcation fate predictor** | 42 pairs (partial) | Initial omega (step-0 TV) is a WEAK predictor of autoregressive grow-vs-collapse fate: TV AUC=0.632 (<0.7 threshold), margin AUC=0.600, TV-fate corr=0.339. **Continuation type dominates fate**: nonvar_42 always collapses (0%), safety_comment mostly collapses (14%), identity/ heavy/type_check ~57% grow. All 42/108 pairs eligible. Omega does not beat simple confidence margin. Supports Fable R5: bimodality is continuation-type-driven, not omega-predictable | |
| 58r | **R6-corrected cross-Q reanalysis** | 0 (analysis) | Fair margin, baseline-flip filter, direct Spearman on #58 data. KEY: assert↔print ρ=0.651 (p=0.003), pooled ρ=0.222. Nothing transfers to addition (neither TV nor margin). Family-dependent, not universal negative | |

| | | | | |
|---|---|---|---|---|
| R6 | **Fable strategic review R6** | — | Five problems with #58 design: comparison Q readout-mismatched, margin baseline unfair, low power, no baseline-flip filter, Spearman is primary quantity. Reframes: TV<margin/2 is a theorem. Omega's value is as certificate, not flip predictor | |
| E1 | **Token-persisted bifurcation rerun** | ~144 trajectories | RUNNING (5/72 conditions). R5 Priority #1. Early data: 3/5 conditions show UNSTABLE labels (change with horizon), supporting greedy-artifact hypothesis | |
| E2 | **Null control + distributional TV** | ~1500 fwd | QUEUED. R5 Priority #2. ARM1: arbitrary edits (not equiv pairs) give same grow rate? ARM2: T=0.7 sampling preserves bimodality? | |
| 65 | **Composition ordering** | 473 | **NON-COMMUTATIVE**: neutral_then_identity amplifies 2.1x above identity alone (0.100 vs 0.047). 7.3x asymmetry on verified/bare pair. 4x on neutral/identity vs reverse. Order of continuations matters dramatically. Static omega data (not trajectory) | |
| 64 | **Perturbation zoo** | 360 | 15 novel perturbation types mapped. Flip DIRECTION matters: if_pass pushes toward attractor 9, assign_zero pulls away. bool_var highest TV amplification (12.9x) but zero flips. TV magnitude ≠ flip risk — directional relationship to decision boundary determines outcome. 5 flips across 168 eligible combinations | |
| 63b | **Full-vocab incremental** | 0 (analysis) | Confirms #55b: full-vocab ≡ 11-bin (corr=1.0, AUC=0.832 all 4 combos). Flip cells 2.95x higher TV. Per Fable R5: same-readout robustness check, not direction-changing | |

| | | | | |
|---|---|---|---|---|
| 63 | **Full-vocab consequence** | 288 | Full-vocab TV adds nothing over 11-bin for code pairs. TV ratio fullvocab/11-bin = 1.0004. Same 6 flips, same correlations (0.347), same accuracy (78.1%). 11-bin readout is sufficient for this domain | |
| 62 | **Omega incremental value** | 0 (analysis) | Margin alone AUC=0.977, adding omega DECREASES to 0.963. □□ **Fable R5 caveat**: same-readout null on 7 flips, no eligibility filter. Margin trivially wins when both computed from same 11-bin readout. UNTESTED, not dead — cross-question #58 is the admissible test | |
| 61 | **Bifurcation predictor** | 0 (analysis) | Initial TV predicts autoregressive growth with AUC=0.676, r=+0.327. BUT continuation type dominates: identity 88% grow, heavy 75%, empty/nonvar 38%. □□ **Fable R5**: autoregressive bimodality (#56) is greedy-decode artifact — need temperature experiment | |
| 60 | **Baseline feature comparison** | 0 (analysis) | Margin (r=-0.406, F1=0.632) beats omega (r=+0.272, F1=0.326). □□ **Fable R5 caveat**: same-readout null on 7 flips. Margin beating omega is trivially expected when both share readout. Cross-question test (#58) needed | |

| | | | | |
|---|---|---|---|---|
| 59 | **Digit-prior sweep** | 576 | **RIVAL_FAILS on stable cells**: Leading-digit match rate 9.7% (chance). Argmax perfectly tracks cell value {1,2,3,5,6,7} regardless of `_ = k` literal — zero flips across all 576 readouts. Attractor prediction (digit=9 lower TV) holds weakly (0.027 vs 0.033). □□ **Caveat**: cells used (vals 1-7) are high-confidence; original R4 digit-copying claim was on uncertain cells. Test does NOT cover the uncertain-cell regime. **New finding**: literal-cell-value INTERFERENCE — when literal matches cell val, TV is HIGHER (e.g. nonvar_3 on val=3: 0.075 vs 0.027 on val≠3), suggesting collision not reinforcement | |
| 58 | **Cross-question consequence** | 500 (80 pairs after filtering) | **FAMILY-DEPENDENT TRANSFER (R6-corrected).** Mean transfer TV AUC=0.498 (chance). BUT assert↔print Spearman ρ=0.651 (p=0.003) — genuine intra-family transfer. Addition shows no stability (ρ=-0.135, 0.057). Fair margin ALSO fails at transfer (AUC 0.386). Same-Q certificate: 0/49 violations; cross-Q: 7-20% violations. Verdict: omega is question-FAMILY-dependent. Within coherent families (questions probing same state), omega transfers. Across family boundaries, nothing transfers | |

| | | | | |
|---|---|---|---|---|
| 57 | **Length scaling** | 1008 | **TYPE-DEPENDENT**: heavy shows INVERTED-U (peak n=1-2, omega 0.106-0.126, then declines to 0.077 at n=12). identity is STEP FUNCTION (2.25x at n=1, flat after). nonvar shows persistent LOG growth (0.029 to 0.121 at n=12). comment SUPPRESSIVE (0.91x, below baseline). Steepest initial step: heavy 3.69x. Most sustained: nonvar. Pair-dependent: strong_assert_2/nonvar monotonic to 0.241; boundary_pair/heavy peaks n=1-2 then drops to baseline. More heavy lines = LESS sensitivity | |
| 56 | **Autoregressive compounding** | 1984 | **BIMODAL**: Omega over 30 generated tokens grows 12.1x overall (TV 0.048->0.582). BUT outcome is binary: 19/32 pairs grow to TV~0.95 (near-total divergence), 13/32 collapse to TV~0.0001 (convergence). Zero stable. identity most reliable amplifier (7/8 grow, final TV=0.855); heavy 6/8; empty and nonvar_42 coin flips (3/8). Critical transition at steps 4-8: abrupt phase jump within 1-2 tokens. Pair type secondary to continuation type | |
| 55 | **Cross-model consequence** | 432 | **NEGATIVE**: tau=0.3 from 1.7B does NOT transfer. 0.6B: 2.3% acc (near-chance), r=0.307, best F1=0.143 at tau=0.05, 1 flip/108 pairs. 4B: 91.2% acc, r=0.284, best F1=0.333 at tau=0.15, 3 flips/108 pairs. Ref 1.7B: r=0.677, F1=0.75. Sweet spot at 1.7B; 0.6B too weak, 4B too robust. Correlation NOT monotonic with scale | |

| | | | | |
|---|---|---|---|---|
| 54 | **Identity paradox (BASE model)** | 288 | Identity HAS 11.1% flip rate on base model (TV=0.042). 0% flip rate in #49 was instruct-model bug. nonvar_42: 0% flips despite TV=0.034 (rank_corr=0.990, top3=1.00) — true rotation-like change. heavy: 22.2% flips, TV=0.074. Different continuations produce structurally different distributional changes | |
| 53 | **Prospective consequence (BASE)** | 576 | **NEGATIVE on base**: Train F1=0.220, Test F1=0.129±0.075, generalization 58.6%, test r=0.222. Fork agent's instruct results (F1=0.696) do NOT replicate on base model. Omega is a weak argmax-flip predictor without RLHF | |
| 52 | **State reconstruction** | 240 | Canonical records tautological TV=0 (both surfaces → identical text). Appended overwrite AMPLIFIES 6x on target_query, reduces ortho_query. Repair shifts sensitivity | |
| 51 | **Referent/name/query crossover** | 384 | Dual-variable design: target-specificity index = -0.008 (negative). Amplification general, not referent-specific. Baseline gap explains apparent 5x | |
| 50c | **Referent test** | 252 | **REVERSAL**: tracked-var continuations SUPPRESS omega (0.085), not amplify. tracked_value (var=val) near-zero (0.035). other_var_identity (w=w) HIGHEST (0.339), exceeding baseline (0.296). Gradient tracked>other>none is FALSE. Tracked var acts as re-anchoring mechanism | |
| 50b | Task transfer (arithmetic) | 270 | heavy is TASK-GENERAL (omega=0.186, 19x identity). safety_donot is TASK-SPECIFIC (0.003 on arithmetic vs 0.09 on scoping). Neutral near-zero on arithmetic | |

| | | | | |
|---|---|---|---|---|
| 49b | **Consequence prediction (INSTRUCT)** | 288 | On Qwen3-1.7B (instruct, model-id bug): r_pb=0.677, F1=0.750 at tau=0.3. Does NOT replicate on base model (#53). RLHF-specific | |
| 48b | Safety comments on instruct | 432 | RLHF POLARIZES omega: heavy amplified 1.7-1.9x, neutral 3.8x on tight pairs. Safety/certainty SUPPRESSED (0.07-0.19x). Pair-dependent: safety_donot 7.4x tight, 1.0x wide | |
| — | **Revival** | 1584 | **MAJOR**: contracted distinctions CAN be revived. reassign_42 contracts 0.32x; none_assign+isinstance_check revives 2.6x. del_var amplifies 3.27x. "Close now" ≠ "interchangeable later" | |
| — | State reconstruction vs repair | 240 | Canonical records tautological TV=0 (design flaw). Appended overwrite AMPLIFIES 6x. Shifts sensitivity, doesn't repair | |
| — | Referent/name/query crossover | 384 | Amplification is **GENERAL**, not referent-specific. Target-specificity index = -0.008. Mentioning target amplifies OTHER query 5x more | |
| — | Boundary-preserving syntax | 192 | Confound real but effect survives. bare_var_nl (25x) strongest. nonvar_expr (10x) = identity. Computation context, not variable reference | |
| — | **Fable R3 corrections** | 0 (review) | **#38 boundary confound**; **#40 NN has no var**; **#45 circular score**; **#39 heterogeneous**. Pivot: predict failures, not catalog amplifiers | |
| 50 | NL full-vocab omega | 160 | **MAJOR**: NL omega (5-17x) EXCEEDS code omega (2-5x) with full-vocab TV. Domain gap was entirely 11-bin artifact | |
| 39 | Matched measurement reanalysis | 0 (reanalysis) | CORRECTS #33: on matched cells instruct heavy RISES #3→#1 (4.6x); NL 11-bin TV=0 (artifact) | |

| | | | | |
|---|---|---|---|---|
| 49 | Meta-analysis | 0 (analysis) | heavy_bare ONLY universal amplifier (100%); identity_bare universal preserver (0%); neutral 67%; all comments preserve; pass > identity | |
| 48 | Safety comments on instruct | — | Running: does safety_donot amplification hold on instruct model? | |
| 47 | Chain amplification | 300 | Neutral GROWS monotonically (4.4x over 3 steps); identity saturates; HN=0.564 worst combo; neutral accumulation more dangerous than mutations | |
| 46 | Baseline predictor | 0 (analysis) | Baseline TV predicts omega (rho=0.74); BUT inverted on tight pairs (rho=-0.31); safest-looking pairs most vulnerable | |
| 45 | Minimal diagnostic set | 0 (analysis) | 3-probe set {comment_var, type_check, var_only} achieves rho=0.61; binary screening works, point prediction limited | |
| 44 | Comment taxonomy | 504 | Safety comments AMPLIFY 7.45x; deprecation SUPPRESSES 0.15x; "do not modify" increases sensitivity opposite of intent | |
| 43 | Authority framing | 288 | Doc frame SUPPRESSES neutral 97% on tight pairs but AMPLIFIES 3.5x on wide pairs; omega is frame-sensitive | |
| 48 | Fixed-cell comparison | 360 | On fixed cells: nonvar_42 beats identity 2/3 pairs (max), 3/3 (mean). Value matters: 42 vs 99 = 2.5x. Double nonvar < single. Token-specific modulation | |
| 46 | Boundary-preserving syntax crossover | 192 | Boundary artifact CONFIRMED (4.19x). Valid amplification survives (25x). `_ = 42` beats identity at tau=0.01 — amplification is computation context, not variable reference | |
| 44 | Pair property analysis | 576 | REFUTES strong/tight hypothesis: identity amplifies only 2/8 pairs; heavy universal; no simple predictor (category/TV/tokens) | |

| | | | | |
|---|---|---|---|---|
| 41 | Layer scaling (0.6B vs 1.7B) | 210 | 0.6B onset at L8 (vs L20 in 1.7B); more distributed profile; larger models concentrate omega in late layers | |
| 40 | Repetition disentanglement | 540 | Pair-dependent opposing effects: strong pairs additive/last-wins; tight pairs suppressive/first-wins; I_paraphrase ≠ I | |
| 38 | Partial identity tokens | 720 | No single trigger; progressive buildup x(0.057)→x=(0.304)→x=x(0.687); newline REDUCES 4x; pair-dependent | |
| 37 | Systematic NL pair discovery v2 | 132 | FIRST NL pair at tau=0.05: passive voice "passed by"/"enacted by" (TV=0.028); 12x amplification | |
| 36 | Cross-arch instruct (StableLM) | 288 | RLHF reshaping REPLICATES but INVERTED: StableLM heavy #5→#1, neutral #1→#4 (opposite of Qwen3) | |
| 35 | Layer-wise fingerprint | 210 | Monotonically increasing; omega=0 in L0-16; onset at L20; 100x jump L16→L20; concentrated in final 30% | |
| 34 | Quantization (int8) | 288 | INT8 DESTROYS identity signal (#1→#5); safety certs NOT quant-invariant; TV(fp32,int8)=0.378 | |
| 33 | Base vs instruct | 288 | RLHF reshapes omega: heavy #1→#4, neutral #5→#2 (amplifies); omega detects alignment fingerprint | |
| 32 | Natural language omega | 130 | Omega EXISTS in NL; tau=0.10 needed (not 0.05); ". " strongest amplifier (3.1x); domain-general framework | |
| 31 | Phase transition | 204 | Step function at rep=1 (0.003→0.047); NO gradual ramp; rep_2 < rep_1 (interference) | |
| 30 | Bootstrap CIs | 0 (analysis) | Cohen's d=3.49, p=0.0004 for identity vs neutral | |
| 29 | Held-out prediction | 312 | 83.3% at tau=0.05, +33pp over naive baseline | |
| 28 | Multi-variable scope | 288 | type_check 2.3× stronger with 2+ vars in scope | |
| 27 | Variable name sensitivity | 144 | Name-length independent pattern; magnitude varies | |

| | | | | |
|---|---|---|---|---|
| 26 | Gemma-3-1b replication | 144 | CONFIRMS omega; pass>neutral>identity (inverted) | |
| 25 | Architecture replication (Pythia, StableLM) | 288 | Pythia=zero; StableLM=intermediate | |
| 24 | Structure transfer (4 code structures) | 576 | class_method=zero amplification; nested_func strongest | |
| 23 | Rank-correlation transfer | 0 (analysis) | Spearman rho=0.52; rank predictor 71-86% at tau=0.01 | |
| 22 | Max-over-pairs analysis | 0 (analysis) | Does NOT fix multi-pair mixing at tight tau | |
| 21 | Perturbation diversity (14 types) | 360 | ALL 14 novel perturbation types amplify at tau=0.01 | |
| 20 | Scaling (0.6B/1.7B/4B) | 432 | Identity amplification scales monotonically: 0.003/0.014/0.051 | |
| 19 | Pair x depth interaction | 720 | All 5 pairs work at all depths; identity increases with depth | |
| 18 | Multi-pair randomized splits | 0 (analysis) | Omega is pair-dependent; loses to code-comment at tau=0.01 | |
| 17 | Cross-model (Qwen3-0.6B, GPT-2) | 288 | GPT-2 zero; 0.6B intermediate; scales with capacity | |
| 16 | Cross-query transfer | 288 | 100% accuracy at tau=0.02 both directions | |
| 15 | Pair transfer (leave-one-out) | 480 | +27.5pp over baseline at tau=0.01 | |
| 14 | Repair/undo chains | 432 | Neutral AMPLIFIES identity; amplification irreversible | |
| 13 | Measurement stability | 96 | Perfectly deterministic (zero TV between runs) | |
| 12 | Token ablation on identity | 480 | Variable mention drives amplification; just_var > identity | |
| 11 | Surface pair discovery | 360 | 12+ eligible pairs from 30 candidates | |
| 10 | Templates (5 structures) | 720 | All 5 structures show same omega pattern | |
| 9 | Transfer (cross-variable) | 432 | Train on x, predict y,z: 83-92% | |
| 8 | Gradient (semantic) | 384 | Smooth gradient from neutral to heavy | |
| 7 | Queries (format sensitivity) | 576 | Robust across query formats | |
| 6 | Values (1-9 sensitivity) | 1,080 | Value-independent | |
| 5 | Depth (2/3/4 nesting) | 1,152 | Deeper nesting = stronger amplification | |
| 4 | Composition (chain effects) | 1,032 | Non-linear; neutral catalyzes identity | |
| 3 | Controls (baselines) | 984 | Baselines validated | |

| | | | | |
|---|---|---|---|---|
| 2 | Prospective prediction test | 0 (analysis) | Omega predicts preservation at 79% | |
| 1 | Fast sweep (core effect) | 3,528 | Core omega effect established | |

### Verdict (updated post-architecture replication):

**Structured positive, cross-architecture.** Omega is a real phenomenon confirmed in 3 architecture families (Qwen3, StableLM, Gemma). Code continuations amplify behavioral distance universally, but WHICH continuations amplify most is model-dependent:

- Qwen3: identity > type_check > heavy > neutral
- StableLM: neutral > type_check > heavy > identity
- Gemma: pass > neutral > type_check > identity
- Pythia: zero (insufficient code training at 1.4B)

Scales monotonically with model capacity (Qwen3 family). Generalizes across variables, code structures, query formats, perturbation types (14/14 amplify). Partially transfers across surface-pair families via ranking (rho=0.52). Operational threshold: tau=0.05.

~32,000+ readouts across 62+ experiments, 5 model architectures. Results in experiments/results/omega_*/. Fable reviews in experiments/results/fable_omega_review_{1,2,3,4}.md.

### Fable R4 Corrections (2026-09-17):

**Devastating reanalysis.** R4 identified that the program quietly stopped measuring omega (eligibility filter dropped since #46). Key corrections:

- nonvar_42 is **digit copying** (argmax→"4" in 20/36 readouts), not computation context
- Revival revised: 9/30 chains on eligible cells (stronger than R4's 1/25 on unfiltered)
- Consequence AUC=0.918 on eligible cells survives correction
- Gradient reversal, state confirmation anchor, TSI, value-matters 2.5x: **WITHDRAWN**
- Cross-question transfer: **UNTESTED** — that's the real omega claim (exp #58 running)
- Margin (confidence gap) **DOMINATES** omega for same-question flip prediction (AUC 0.977 vs 0.838)
- Omega has **NEGATIVE** incremental value beyond margin (-0.018 delta AUC)
- Length scaling reveals 3 dynamical signatures: heavy decays, identity saturates, nonvar accumulates

### Revised Verdict (post-R4):

**Omega is a real measurable phenomenon but NOT a useful predictor beyond simple confidence margin for same-question tasks.** The remaining theoretical claim — cross-question certification — is under test (exp #58). If omega predicts behavior under Q2 from measurements under Q1 better than running Q2 directly, it has genuine value as a cheap certification tool.
If not, the program reduces to "TV between surface pairs is a noisy proxy for confidence."

## S65 supplied-revision diagnostic and user pause — 2026-09-14

Research is paused; no run is active or queued. Retry completed all 18 responses, all terminated (3/3 per arm). Original citizenship 2/3, supplied citizenship 3/3, capital prerequisites 0/3, supplied composed capital 0/3. Zero prerequisite-eligible cases; do not infer missing knowledge or failed competent composition. All outputs were manually reviewed by root and two independent reviewers. One wrong-subject record is misattributed at country level. Full evidence: `results/relation_revision_v1/`.

First attempt failed serialization after one generation: 81.698 seconds, zero saved responses, unrecorded 1–16 forwards. Retry: 51.476 seconds,111 recorded forwards;

combined133.174 seconds,112–127 forwards. Session: nine probe blocks,666 recorded plus1–16 unrecorded calls (667–682 total),1710 apparatus/0 artifact lines. No GPU. Natural capital questions are an unrun restart candidate, not a queued experiment.

## S64 recovery attribution and direction check — 2026-09-14

Temporal-state migration is not selected before a useful upgrade. The bounded source contrast separates added-feature segmentation quality from recovery-specific evidence and identifies memory/search without new weights as a direct comparator. Final-trajectory selection differs from immediate decisions. Canonical S64 and ledger preserve sources and reviewer provenance. No new probe, forward or apparatus.

## S63 temporal-operation source check — 2026-09-14

One primary source and independent review identify contributed features inside next-frame object association and granularity control. The encoder is frozen but the decoder and new temporal components receive training. Mixed ablation effects, oracle-mask diagnostic scope and inconsistent default table figures are preserved; no general information-absence or repeated-acquisition claim. No new empirical block, model forward or apparatus. Canonical S63 and ledger retain provenance.

## S62 later-attribute interface comparison — 2026-09-14 (completed)

On fourteen disjoint qualifying test pairs / 31 color questions, mean within-pair annotation-agreement scores are .630952 for specialist features, .607143 for all raw logits and .690476 for existing recipient features. Features beat logits on two pairs, lose on two and tie on ten. Independent audit exactly reproduces all predictions, vote aggregation, spectra and scores. Thirty-six readers attain 15 slope degrees of freedom; nine are deliberate constants. These are same-family supervised readers, not zero-shot later questions.

Selected visual review finds body-region/visibility ambiguity in three pairs. No exclusions or rescoring: retain dataset-agreement scope, not verified color perception. This panel does not justify requiring specialist features; no universal logit sufficiency or intrinsic representation-hole result. Close without tuning.

New cost: 180 CPU forward calls, 19.627 supervised extraction seconds; 45 reader preparations, 5.464 supervised fitting seconds; 4,686,432 test-annotation bytes. All reproduced logits match the previous cache exactly. Runner 222 apparatus lines; session eight blocks, 555 forward calls (fifteen earlier batched), 1573/0 code lines. No GPU or new weights. Raw votes, design, attempts, extraction and result are in `results/attribute_comparison_v1/`; S62 holds full qualifications and timing scopes.

## S61 source resolution and S62 annotation feasibility — 2026-09-14

S61 distinguishes useful resolution repair from matched-effort causal attribution and prior-service retention. Its source inquiry is closed. S62 independently verifies 26 discordant training pairs across six species for fixed breast-color questions: 54 pair–color comparisons, not independent observations. All 1800 raw training votes reproduce the aggregates (1440 known, 360 unknown); there is one vote per image–attribute. Initial extraction: 3,949,152 bytes / 21.62 seconds;

additional raw-vote custody fetch: 3,900,000 bytes / 1.586 seconds. Test attributes remain unexamined. Frozen design selects a bounded matched-reader probe, not yet run. No new model block, forward, fitted reader or runner at this checkpoint. Receipts: `results/attribute_comparison_v1/`; canonical S61/S62 and ledger.

## S59–S60 strategy after the teaching result — 2026-09-14

Two-round review declines a hierarchical-versus-flat classifier run: the direct union head can retain the old scoped head and reuse the same features. No actual resource constraint motivates the added hierarchy. S60 independently checks a primary multi-teacher representation precedent, distinguishing frozen-backbone downstream readers from unchanged teacher consumers. No local run or new apparatus; seven blocks, 375 backbone evaluations and 1351/0 code lines remain unchanged. Canonical S59/S60 and the ledger retain the analytical and source boundaries.

## S58 bounded specialist-teaching precursor — 2026-09-14 (completed)

Fresh review corrects an unrun selection criterion; the selected limited-label teaching question now has a result, independently reproduced from cached tensors.

| Test correct / 60 | Label draw 0 | Label draw 1 | Label draw 2 |
|---|---|---|---|
| 18 labels only | 52 | 49 | 52 |
| Hard teacher targets | 59 | 59 | 58 |
| Soft teacher targets | 57 | 52 | 55 |
| 120-label reference | 59 | 59 | 59 |

All draws reuse the same sixty test images. Hard teaching corrects 7/10/6 mistakes with zero regressions against label-only. Teacher hard targets equal all 120 training truths: ordinary additional correct supervision explains the improvement. Teacher test accuracy is 56/60 full-vocabulary, 59/60 restricted to the six classes. No soft-information advantage, new backbone knowledge or cumulative claim.

CPU preparation: 285.14 seconds, 18.85 MB images and 52.64 MB model archives. Compute supervisors: 34.95 seconds total; 360 image-level backbone evaluations, 2400 head optimization steps, twelve candidate heads. All attempts completed. Runner: 286 apparatus lines, zero reusable artifact-bearing code lines. Session: seven probe blocks, 375 backbone evaluations, 1351/0 lines. No GPU or panel tuning. Manifest, preparation, attempts, cache blocks and predictions are retained in `results/species_teaching_v1/`; canonical S58 explains scope and provenance.

## S57 prepared intervention source contrast — 2026-09-14

One source and independent review identify an offline-prepared recipient write vector, distinct from S56 live paired reconstruction. Method-level dependency and selected behavioral illustrations do not establish implementation timings, new expertise or cumulative composition. No model run or new apparatus.

## S56 feature-to-operation source check — 2026-09-14

One primary report and pinned implementation distinguish behavioral modulation from executable grafting. Independent review checks the offered-name scorer, live paired-model input and the masked recipient write path. A static wrong-tool

counterexample is not a model failure rate. No model run, scorer execution, new probe block or runner; six blocks/fifteen forwards and1065/0 lines unchanged. The canonical S56 section and ledger hold provenance and qualifications.

## S55 prediction-resource resolution — 2026-09-14

A bounded check identifies a small published species predictor and accessible image/caption row metadata. No model or image was downloaded. Dataset authors warn of ImageNet overlap; label order and mirror split provenance are unbound. Independent review declines the isolated species-head run because its outcomes do not resolve the active operational-composition decision. Availability is no longer the deferral reason. No new empirical block, forward or runner line.

## S55 species-teaching comparator clarification — 2026-09-14

Two-round strategy dialogue selects one bounded resource-feasibility allocation for a possible explicit species service. A generalist without species outputs is not a valid species-teaching comparator. Label-only, soft specialist teaching and hard pseudo-label teaching must declare supervision and cost. This is ordinary assimilation feasibility, not shared-suffix reuse or joint reasoning. No new run, empirical block, model forward or apparatus line. Details remain in S55.

## S53 reaction-consequence source contract — 2026-09-14

One specialist source and two-round direction review select conditional structural questions about a predicted product as a consumer-access candidate. A Table 1 illustration was manually traced for four input/output membership cases. This is not a parser/model run, reaction benchmark or new local empirical block. RDKit availability was checked read-only; no dependency was installed. The reviewed cost comparison credits decoding/retaining a graph once. No source generation score is promoted to local quality evidence; model/reader selection and fitting remain unrun.

## S52 predicted consequences and later-use objective — 2026-09-14

Analytical application of the existing consumer loss separates marginal answers from shared-analysis use. Independent two-round review verifies the KL decomposition and keeps correctness distinct from teacher agreement. Separate donor-trained ports need not modify previous ports. A direct learner may predict and retain a sufficient record once; repeated-inference baselines would be unfair. No new theorem framework, runner, local empirical block or model forward. Six blocks/fifteen scored forwards and1065 apparatus/0 artifact-bearing lines remain unchanged.

## Fresh periodic approach review — 2026-09-14, around 15:30 UTC

After62f85fe and separate entropy checking, independent fresh subagent review distinguishes unchanged connected growth from shared updates and distinguishes native-input from induced-input component replay. Joint-service replay is not necessarily required. A worked hypothetical depth-boundary failure prioritizes available output/image evidence and direct learned repair as comparators; it is not an empirical block. Next selection needs a testable useful benefit of sharing

or assimilation, not prior proof of superiority. No real CLI audit or new runner.

## S51 depth-selection interface and endpoint boundary — 2026-09-14

A raw relative-depth interface makes category/depth pixel selection expressible without learned alignment. This is source/code analysis, not demonstrated quality. A limited check did not bind the specific trained semantic/spatial endpoint; local execution of that exact episode closes without extending the search or substituting a new model under old claims. Independent two-round dialogue favored the complete-episode dependency check over a standalone depth demonstration. No new empirical block, model forward or runner; accounting remains unchanged.

## S50 concrete acquisition reference — 2026-09-14

Source study of a semantic/spatial merger identifies original-operation retention measurements and a useful joint behavior, with teacher, prompt and resolution confounds limiting attribution. The original spatial API accepts dense masks as well as points; matching that guidance is expressible but untested in this study. Canonical S50 retains final-paper custody, separately identified author appendices, the pinned predictor interface and independent review provenance. This is a source result, not a local empirical block. Six blocks, fifteen scored model forwards, 1065 apparatus /0 artifact-bearing lines remain unchanged. No reproduction selected. The worked replay-source proposal finds that unlabeled images can support generated joint-service targets only after selecting vocabulary/request support and a sampling policy. The student must run its own path. Equal-budget ingredient replay is the comparison; no training or new empirical block follows from this derivation.

## Mission-coverage consolidation — 2026-09-14

Current map and routing consolidated through S49; no new empirical block. Earlier four negatives, two failed S37 attempts within its block, and S47's direct-method success retain their scopes. Six blocks, fifteen scored model forwards,1065 apparatus /0 artifact-bearing code lines. Current notebook's stale958/five count corrected. Useful contribution need not add novel information. The missing acquisition episode must identify supported prior A, new B and retained joint use; repeated queries over a saved export alone do not satisfy that requirement.

## S49 saved exports and later requests — 2026-09-14

Pinned source inspection finds that supplying a saved reconstruction export bypasses fresh query encoding. A separate prepared context-compression interface actually combines memory with a later prompt, supported by source training and evaluation. Its multi-span result required extra training on the concatenation pattern; it is not independent-donor composition. No local model run or acquired artifact. Canonical S49 and two `s49_*_20260914` ledger entries retain code/PDF hashes and independent reviewer provenance. Accounting remains unchanged. Further S49 review retains consumer-response distillation as optional and adds a complete trained-reasoning comparator with rationale-preserving no-alignment control. Traced hidden targets depend on changing shared parameters. Official

small-checkpoint availability is confirmed, then closed without download or execution after independent direction review; two additional S49 ledger records preserve the receipt and disposition. No new theorem section or runner.

## S48 transported operation contract — 2026-09-14

Primary source and independent algebra separate a transported direction from the complete read/write intervention. Affine transport, descent through a noninjective export and clamp-order effects are diagnostic; the inspected method recalibrates the recipient and does not promise exact conjugacy. A later operation must justify its remaining recipient-specific preparation against direct learning. No new model run or apparatus; local totals remain six probe blocks,15 scored model forwards and1065 apparatus /0 artifact-bearing physical code lines. Canonical S48 and ledger `s48_transported_operation_contract_20260914` carry provenance and limits. Continuation: accumulating a full positive centroid during recipient clamp calibration needs no extra model forwards. A declared reusable reference enables a direct direction comparator on those positives; reference quality is unproven. Readout reuse and state-update transfer have different preparation obligations. Ledger `s48_shared_calibration_comparator_20260914`; no new empirical block.

## S47 real evidence selection and direct remedy — 2026-09-14

Fixed five report pairs, ten prompts; four pairs semantically usable with an exact source-bound annotation per question. One ratio/denominator mismatch excluded without replacement; one malformed offset retained alongside an exact alternative. Fifteen of sixteen abstract annotation rows match exclusive-end indexing, including duplicates. On eight eligible structured outcome queries, ordinary lexical matching selects adequate evidence for7/8 across full abstracts and8/8 with supplied RESULTS filtering; paired adequacy3/4 versus4/4. One mixed-quality top tie remains in the RESULTS arm. Root and independent reviewer read every selected sentence and tie. CPU-only subprocess0.3406s from cached sources, excluding preparation; no model. Canonical storage/I-O replay preserves all16 decisions and input custody. Panel closed without learned model, expansion or acquisition claim. One runner107 lines, one result JSON. Totals: six local probe blocks,15 scored model forwards,1065 apparatus /0 artifact-bearing physical code lines; S43 external inspection separate. See canonical S47 and ledger `s47_evidence_selection_null_result_20260914`.

## S46 direct operation teaching comparator — 2026-09-14

Two-round independent dialogue prioritizes direct conditional preference teaching over full-answer representations for the specified retrieval endpoint. A contrast dictionary otherwise hides an unproven semantic interpreter. Donor-written bounded executable predicates remain a conditional alternative; no parser is built. Richer exports may earn their cost through later-operation reuse, which retrieval alone cannot show. Theory only; empirical totals unchanged. Ledger: `s46_direct_preference_competitor_20260914`.

## S44-S45 conditional evidence selection — 2026-09-14

One source-reconfirmed worked retrieval request fixes the offered operation. A prospective reversal contrast asks whether the same evidence is preferred appropriately for different questions on unfamiliar records. Fresh donor answers at inference are additional information, not an equal-information teaching arm. Independent strategy dialogue rejected an uninformative four-record model check. No model loaded, runner added or acquisition demonstrated; numerical thresholds and an empirical panel remain unselected. See canonical S44-S45 and ledger `s44_s45_conditional_evidence_selection_20260914`. Empirical totals unchanged.

## S43 bounded teaching-target inspection — 2026-09-14

Read 32 published responses for a fixed first16 identical queries; row-service revision headers match dataset commit, ids/text match, no transport truncation. Generation finish metadata is absent and many stored answers visibly stop early. One complete counting correction is independently verified:136 versus76; shared errors and partial answers make whole donor responses unreliable as gold. No comparative accuracy, termination, acquisition or latent-transfer claim. Fixed slice closed without expansion. One retained result JSON; no new runner/model inference. Local totals remain five probe blocks and15 scored CPU forwards; this external-output inspection is counted separately. Ledger: s43_teaching_target_slice_20260914.

## S42 response-derived teaching and computation reuse — 2026-09-14

Primary-source and independent strategy reviews distinguish answer generator, embedding teacher and predictive backbone. A pooled retrieval vector differs from a decodable soft-prompt sequence; latent chaining remains future work. Smaller cache adapters need not make total fitting cheap. A causal-prefix reuse argument is independently checked, with isolated-branch, frozen-policy and generation-vocabulary qualifications. This supports an ordinary teaching comparator and conditional shared-predictor idea, not a build or local acquisition claim. See canonical S42 and ledger. Source/code reads only; empirical totals unchanged.

## S40–S41 separate preparation and joint use — 2026-09-14

Primary source and pinned implementation review find a constructive precedent for joint use of separately trained donor interfaces. Parallel residual summation and sequential fusion are distinct operators; neither freezes an entire prior receiver trajectory. Released candidate interfaces exist, but exact joint-run configuration and item-level retention remain unbound in the checked material. A frozen-query attention identity is independently verified and retained as a diagnostic, not a new instrumentation program. See canonical S40–S41 and matching ledger entries. No local model run, training, weights download or new runner; totals unchanged: 15 scored CPU forwards, five probe blocks, 958 apparatus / 0 artifact-bearing lines.

## S39 live latent communication source check — 2026-09-14

Pinned source and independent strategy review separate same-model cache reuse from heterogeneous contributor admission. The official core uses one model across roles. Pinned community extensions implement actual heterogeneous transport.

A function-body versus complete-function prompt difference identifies the first no-message receiver control; no causal explanation of author results is claimed. Probability-mediated transport preserves a conditional message, not arbitrary latent state. See canonical S39 and ledger. No new execution; totals unchanged.

## S38 strategy resumed — 2026-09-14

Latest user instruction keeps mission fixed and pivots around unavailable tooling. No S37 rerun or CLI repair loop. Conditional transcript simulation sharpened by independent review; teacher target construction and student training pathway are separate acquisition choices. Primary-source checks support an ordinary text-counterfactual comparator and qualify random-network nonlinear alignment through a disjoint-name test. Symbolic-teacher intervention training supplies a student-pathway precedent; ordinary augmentation already solves one behavioral endpoint. A conditional factorization argument identifies when both training paths coincide. See canonical S38 and ledger `s38_*` entries.

No new model forwards or apparatus: totals remain 15 scored CPU forwards, five probe blocks, 958 apparatus / 0 artifact-bearing lines, no GPU or training.

## S37 execution outcome — 2026-09-14

Two bounded attempts, **zero scored forwards**, no scientific result. Attempt 1 hit the 180 s compute deadline (200.42 s total, peak RSS 592,384,000 bytes). Attempt 2 reached alignment in 84.57 s (peak RSS 734,183,424 bytes), then failed because the downloader saved HTTP-compressed metadata without decoding it. Seven gzip files and one Brotli configuration were normalized offline; decoded tokenizers are byte-identical. This is a harness error, not incompatible models. Downloader corrected; no third run in this allocation. Exact raw attempts, hashes, diagnosis and cache correction are in ledger entries `agreement_teaching_preflight_attempt1_20260914` and `agreement_teaching_preflight_attempt2_20260914`. Two real CLI audit attempts remain incomplete because file reads failed; separate collaboration custody checks verified counts, reconstructed sources and normalized metadata, not a scientific result or independently replayed decompression.

Accounting: five probe blocks (two execution attempts in S37), 15 total scored CPU forwards, 958 apparatus / 0 artifact-bearing lines, zero building rounds, no GPU or training. Scientific competence/headroom/intervention claims untested.

## S37 preflight locked — 2026-09-14

User-requested renewed reviews demote S36 query compatibility as first priority. One fixed CPU-only agreement intervention preflight is justified after actual-file design review and resource/alignment/checkpoint corrections. No training or generation. Lock, receipts and hashes: `agreement_teaching_preflight_lock_20260914`. Execution failures are inconclusive. Result pending; historical selections below are superseded by this reassessment.

## Application selected — 2026-09-14, 03:42 UTC

Two fresh dialogues select S36's scientific evidence-finding use and initial

query-side compatibility hypothesis, resolving the map audit's selection gap. Mechanism-testing and contrary evidence are the intended new behavior; established topic searches must remain adequate. Expansion, rebuilding and no acquisition are real outcomes. No local collection/model pair/run is claimed ready. Strategy selection is complete; empirical adequacy and value remain open. Receipts and hashes: `application_dialogue_r1_20260914` / `application_dialogue_r2_20260914`. No additional local forwards, GPU or training; four probes and 15 CPU forwards total.

## Strategy map review — 2026-09-14, 03:34 UTC

Fresh unprimed CLI inspected consolidated 7d0a1bf after independent entropy review. Continue; the general map is sufficient, but consequential use and preferred route remain unselected. More definitions are not the next step. S36 works one application choice. Corrected mandatory prior-preparation, cost-superiority and already-successful direct-route wording across current surfaces. No new numerical correction in inspected receipts, not a full numerical reproduction. Audit e1095–e1096; root synthesis complete. Ledger `strategy_map_adversarial_review_20260914`. Next review around 05:34 UTC; accounting remains four probes, 15 CPU forwards, 628:0 code lines, no GPU/training.

## Inheritance framing complete — 2026-09-14

Two fresh direction dialogues close S35's paper analysis. A retained fitting choice is reconstructible from declared historical evidence; its usefulness after a new provider still requires quality/cost evidence. This is a legitimate cheap baseline, not a new admission-learning algorithm or selected experiment. The three empirical uncertainties are useful contribution, retained interpretation/repair and total effort. Stronger learning-to-admit is optional. No model calls or new runner. Receipts: `inheritance_dialogue_r1_20260914` and `inheritance_dialogue_r2_20260914`.

## Candidate proposal decision — 2026-09-14, deferred

S34 now specifies 32 possible fixed candidates, accessible generator/object/scene interfaces, supported truncation control and resource ceilings; no weights acquired or models loaded. Design round 1 added scene-swap and uniform-selection controls, paired object spoils, practical primary thresholds and a 45-minute total-effort cap. Fresh round 2 and root defer execution: uncertain endpoint/compatibility effort outweighs a narrow interface result with no concrete next use. An authenticated source-image reader opened the image but mislocalized colors: file access works, endpoint reliability is unproved. Root and an independent reader cross-checked the figure. This separate source-image call adds no local probe forwards. Receipts and hashes are in `candidate_proposal_dialogue_r1_20260914`, `candidate_proposal_dialogue_r2_20260914` and `source_image_judge_readiness_20260914`.

## Fourth periodic approach review — 2026-09-14, 02:40 UTC

Fresh real CLI reviewed consolidated e72f83d after a separate entropy sweep: continue, revise evidence allocation. Prepare one concrete bounded candidate-data proposal with accessible interfaces, independent coverage/selection judgments, direct controls and resource ceilings; no execution. Low coverage does not choose

guidance over other remedies; provider replacement differs from capability growth. Corrections propagated to canonical/current surfaces. Audit e1086-e1087, root synthesis complete; `strategy_periodic_approach_review_4_20260914` preserves receipt. No numerical correction or new local behavioral result. Accounting remains four probes, 15 CPU forwards, 628:0 code lines. Next review around 04:40 UTC.

## Third periodic approach review — 2026-09-14, 00:54 UTC

Fresh real CLI inspected consolidated 89b34ae and recommends continuing while ending further interface cautions as the default. S27 develops one <=45-minute constructive refresh-versus-maintenance episode, with full refresh as a serious reference and all consumption/decision learning charged. Root challenges whether generic caching would repeat the closed S24 contract. Two direction responses now close S27 through sufficient typed connected refresh and adopt S28's reusable consumer target. Targeted source inspection and S28.1's incremental-reader algebra are complete; neither is a new numerical experiment.
Audit e1061-e1062; exact receipt/hash in ledger `strategy_periodic_approach_review_3_20260914`. No new experiment or model call. Accounting remains 628 apparatus / 0 artifact-bearing code lines, four probes / zero building rounds, 15 model forwards. Next periodic review around 02:54 UTC.

## Reusable operations and grafting — 2026-09-14, source/strategy only

Canonical S29 works a source/operation reuse contract. S30 checks two primary heterogeneous fusion mechanisms and a pinned code release with independent readers. Positive interface reuse and folded weight transfer remain distinct from sequential acquisition. Learning, retained tails, conditional normalization and folding scopes are recorded in the canonical document and `heterogeneous_grafting_source_20260914`. No experiment, model loading or new runner.

## Retained interpretation and migration — 2026-09-14, source/strategy only

Three fresh direction dialogues refine S31's future-operation teaching contract and S32's provider-replacement case. Independently checked published migration tables show why the currently deployed query/gallery pair is the retention reference. No model or economic retirement decision was executed. Source versions, reported points and independent scope checks live in canonical S32 and ledger `migration_retirement_contract_20260914`. Source study adds no empirical probe.

## Intervention teaching contract — 2026-09-14, source/strategy only

Canonical S33 records a primary causal-distillation recipe independently checked against its final paper, plus two fresh direction dialogues. Each model intervenes on its own states; the reusable teaching episode still needs donor-specific correspondence. S33.1 separates auxiliary teaching from promised operations. Positive published task scores do not establish superiority over targeted ordinary teaching at matched total expenditure. Ledger `causal_distillation_source_20260914` and `teaching_retention_contract_20260914` preserve scope. No model or new probe.

## Shared-candidate inference lifecycle — 2026-09-14, source/strategy only

Canonical S34 records an independently checked compositional inference account
and three fresh direction rounds. The candidate-reader lifecycle
dependency/cost account favors completed-candidate coverage and clean evaluation
before trajectory guidance. A pinned source-repository inspection identifies no
eligible candidate bank in its limited scope.
Published prepared composition does not establish the proposed new contribution.
Ledger `compositional_inference_source_20260914` and dialogue receipts preserve
scope. Accounting remains four probes / 15 CPU forwards / 628:0 code lines.
No model, numerical experiment or implementation.

## Continuation and growth contracts — 2026-09-14, mathematics/source only

Canonical S8.1 gives a conditional mean-state closure proof and separates
fixed-action prediction from observation-then-choice. DeepMDP and successor-feature
primary sources supply existing task-relative representation and transfer contracts.
S8.2 gives an exact counterexample to monotonicity of recomputed one-pass GPI
under policy-library inclusion; its standard constituent-policy theorem remains
intact. Retaining and evaluating the previous composed policy restores conditional
retention bounds. Fresh real CLI audit e1056-e1057 checked the witness and scope.
No numerical benchmark, learned-model failure, new latent law or compute run.
Receipts: ledger `mean_state_closure_20260914`, `deepmdp_contract_source_20260914`
and `gpi_growth_math_audit_20260914`. Accounting remains four probes, 15 model
forwards, 628 apparatus / 0 artifact-bearing code lines.

## Autonomous conditional continuation — audited local closure, 2026-09-13

Canonical S26 specifies one bounded CPU strategy diagnostic after two fresh real
CLI direction rounds. All retained variant rows consistently reconstruct four
assay reference constructs (lengths 47/69/64/50); no fitness scores select pairs.
Sixteen fixed pairs test independent, autonomous, reverse, repeat, two oracle and
cyclic-content conditions. Confidence-first scheduling uses no extra forwards.
Installed mask-dropout normalization requires the equal-mask control. Seven
forwards / 112 rows maximum, 180 seconds including startup; timeout is incomplete.
Recovery thresholds are local allocation criteria, not significance or general
reasoning evidence. The single run completed in 10.1455 seconds, seven CPU
forwards / 112 rows. Primary both-site recovery 0/16 matches independent 0/16;
second-site recovery 2/16 matches independent 2/16 and trails cyclic control
3/16. All 16 fixed-position cases complete per arm. Initial first guesses are
correct only 1/16, bounding achievable pair recovery below the locked threshold.
Close this procedure locally; no strong negative about competent composition.
Fresh real CLI audit e1044-e1045 independently reproduced every count and checked
source/custody/code paths; root and auditor read all 16 decoded predictions.
Reverse/confidence-first each correct one and spoil one. Timing is from main,
excluding interpreter startup; raw audit runtime typo is corrected in the ledger. Exact arrays
and provenance are in `results/encoder_continuation_v1/result.json`. Ledger `autonomous_continuation_design_20260913`.

## Second periodic approach review — 2026-09-13, 23:03 UTC

Fresh real CLI review of `f83ce4b` recommends continuing strategy but ending unspecified revision prediction and generic vocabulary expansion as the default. Its decision question is what acquisition or use improves because a revision relation is learned. Next block: at most 45 minutes, one concrete operation, donor evidence, receiver interface and retained use; conclude typed import is sufficient, specify a decision-bearing empirical contrast, or close on an exact missing dependency. No competence proof is required before a probe measuring it. This is an approach review, not a new experiment. Audit entries e1039-e1040; receipt and hash: ledger `strategy_periodic_approach_review_2_20260913`. The subsequent bounded contract closed with outcome 1: S24's authoritative scoped external-record import and stipulated calculator supply the useful operation. No learned predictor is needed there; no real purchasing donor or receiver is asserted. Independent strategy check agreed. Mission e1041 and ledger `scoped_revision_contract_closeout_20260913` retain the scoped result. Accounting at that checkpoint was 421 apparatus / 0 artifact-bearing lines, three probes / zero construction rounds, eight model forwards, no GPU or training.

## Revision consequence identification (2026-09-13; no compute)

Two fresh real Codex CLI design-dialogue rounds produced S24's hypothetical purchasing example and corrected conflation of dependency with observed answer change. The example identifies a missing scope distinction and keeps acquisition evidence separate from later consequence tests. It instantiates prior information arguments and does not establish a learned law. Typed repair is sufficient under the stipulated two-hypothesis contract. A future learned-structure claim must predict actual model behavior without caller-supplied propagation supplying it. No new model call, runner, benchmark, artifact or selected run. Dialogue receipts are in the ledger; this does not replace the scheduled periodic approach review. The existing Geiger2021 causal-abstraction framework now supplies the explicit method bridge in S24, with its task/phrase supervision and sampled scope qualified.

## Acquisition reuse and revision precedents (2026-09-13; strategy only)

Canonical S2.2 specifies a reusable acquisition procedure whose learned outputs may change, with declared evidence/budgets and fresh-input use. S12 adds conditional tied-head parameter bookkeeping; no proprietary model or measured runtime claim. S25 records full-method source readings of MEMOIR v4, RippleEdits TACL2024 and StableEdit v1. These establish relevant published approaches and task contracts, not project replications. Independent reviews distinguish sequential target learning from donor-computation transfer and qualify the semantics of dependency rules. No selected experiment, new runner, model load or training; accounting unchanged.

## Source interpretation and interface repair (2026-09-13; no run)

S3 now incorporates the full official stitching paper: its clustered noise has shared class centres across train/test, and stitch supervision can learn output correspondence. Functional acquisition and preserved donor computation are distinct

claims. S24 traces crop-local mutation and missing inverse-coordinate metadata in the pinned table pipeline. These create caller obligations for a persistent page contract, not evidence of a defective latent space or a selected wrapper project.

README's old "content-driven, not surface-driven" wording is narrowed to the measured assertion-versus-misleading and variable-mention contrasts. The 6.3× number is unchanged; this does not isolate semantics from all surface differences. The historical Gate 1b interpretation below is qualified accordingly. No new model run, training or apparatus; session accounting is unchanged.

## Worked growth episode: source inspection only (2026-09-13)

Canonical S24 uses a released table illustration to assign successive donor contributions and the source of joint-use relationships. OCR supplies text; structure predictions and fixed binding rules supply cells; an existing executor supplies later queries. Two-round design dialogue and independent code reading corrected the attribution of binding and strengthened the structured comparator. No OCR/table pipeline, training or benchmark was run. Metadata confirms exposed component resources only, not task competence. Source image hash and code/model revisions are in the ledger. Session model/probe accounting remains unchanged.

## Specialist task contract: documented case is not discriminating (2026-09-13)

Source inspection, not a new model experiment. At pinned public data revision 9f0ef941a362f0e308e11861ed82c36338e23586, the documented PFN1 test example (row 125) has the exact question and answer of four training rows. Independent verification checked sequence edits, question equality and source hashes. A question dictionary answers this example without DNA; no full-benchmark score or trained-model attribution follows. The curation formatter omits nucleotide changes from questions, and the evaluation loader combines 146 test and 144 validation rows. The latter explains the paper's 290-example table without establishing historical model-selection details.

Close this candidate for the proposed joint-contribution demonstration: missing independent effect contrasts, receiver role-competence evidence and a verified usable original receiver. No new harness, model load or reproduction. The [canonical S8 contract](../theory/CUMULATIVE_CAPABILITY_ACQUISITION.md#s8-what-reasoning-over-an-encoder-could-mean) and ledger retain the exact scope, row locators and hashes. Probe accounting is unchanged; bounded source reads are not additional model experiments.

## Periodic strategy review: task-first selection (2026-09-13; no run)

Fresh real Codex CLI review of HEAD 0a93fb7, audit e1027, finds diminishing returns from availability-led diagnostics. Continue strategy with one documented specialist-encoder joint-task eligibility block, at most 90 minutes; compare structured and richer ports without building either. Require competence in each assigned role, not standalone superiority for all donors. Receiver adaptation must be declared rather than universally banned. S22 stays closed; its failed average does not bar a separately justified richer interface. See the

[canonical next-work boundary](../theory/CUMULATIVE_CAPABILITY_ACQUISITION.md#next-work-boundary).
No new empirical result. Session accounting remains 421/0 apparatus/artifact
lines, three probes/zero building rounds, eight CPU model forwards.

## Cached donor output screen: fixed rule loses (2026-09-13; AUDITED)

S22 prespecified four assays, two columns and an equal within-assay midrank
average before outcome calculation. [Runner](run_cached_donor_screen.py),
[result and subset provenance](results/cached_donor_screen_v1/result.json).
All 8,610 variants share finite identity-matched support; no exclusions. Initial
screen 23.86 seconds including bounded archive retrieval, zero model calls or
training. Corrected combination correlations: -0.205586, 0.313539, 0.238012,
-0.301905; each is below the retrospectively better individual score. Individual
signed correlations match the official per-assay summaries to reported precision.

Fresh real Codex CLI audit e1022 upheld the bounded negative and caught split
mathematical ties from floating normalization. Integer doubled-midrank sums
correct the largest correlation by 0.00001343, without changing the verdict.
Offline correction matches independent SciPy recomputation. Original source and
result remain in commit 0f61942, hashes retained in the corrected result/ledger.
Source agreement is the recorded runner check; audit independently checked the
retained subsets, not discarded full archive members. No tuning or new run.
This is failure of one fixed rule on four descriptive units, not proof of no
complementarity, internal transfer limits, generalization or biological utility.
Session apparatus/artifact: 421/0 lines, three probes, zero construction. No
further averaging/grafting of this pair is selected.

## Conditional-port compatibility: bounded panel (2026-09-13; AUDITED)

[S21](../theory/CUMULATIVE_CAPABILITY_ACQUISITION.md) locked four real-encoder
conditional rectangles after two independent design-dialogue rounds.
[Runner](run_conditional_port_probe.py), [result](results/conditional_port_v1/result.json).
Eight CPU forward calls, 32 rows, no fitting, 60.27 seconds including startup.
Isolated minimum worst-edge corrections range 0.000207–0.028143 nats; all four
are below primary 0.1 and sensitivity 0.05/0.2 tolerances. Repeat/shared-input
checks agree exactly, which does not bound systematic numerical error.
Audited scope: no isolated incompatibility exceeding declared tolerances;
no global consistency, reasoning, biological quality or acquisition claim.
Fresh real Codex CLI audit e1021 upheld conditioning/arithmetic and identified
a post-hoc additive null: one constant preference per site fits all observed
edges within 0.0722242 nats, below primary tolerance. The fixed-reference null
instead has maximum error 0.1444484. These are calculations on recorded data,
not prospective held-out predictors. Practical significance remains unvalidated.
No expanded search selected; next define a task requiring useful updates.
Session apparatus/artifact: 217/0 code lines, two probe rounds, zero construction.

## Strategy checkpoint: contribution and inference contracts (2026-09-13; NO MODEL RUN)

Canonical S16–S20 record analytical examples, primary-source reading and bounded

external artifact eligibility checks. Pinned onboarding source lacks a matched receiver baseline and replacement-contribution controls. Three inspected result JSONs have no per-example messages/labels for an alternative-reader replay. No external script, model or tensor was loaded; these are source assessments, not a reproduction or a new model result. Added the current decision map and narrowed next work to at most two actual interfaces. Session apparatus/artifact remains 98/0 lines; one integrity probe, zero construction rounds. Explicit strategy-only mandate governs. References and precise scope live in S18.

## Strategy refined: interchange and extension (2026-09-13; NO MODEL RUN)

Canonical strategy S11–S15 records operational port contracts, conditional bounds and independent approach dialogues. Scene/assignment runs were not selected; structured interfaces remain serious alternatives. No further compute or capability result. Session apparatus/artifact remains 98/0 lines, one integrity probe and zero construction rounds; the explicit strategy-only mandate governs. Integrity audit references corrected to e1011–e1012 after a stale-writer collision; the append-only ledger preserves the correction and root now serializes writes.

## Acquisition cache eligibility: retained exports unsuitable (2026-09-13)

Small read-only CPU probe of two legacy 55 MB latent bundles; no models loaded, no fitting, no capability evaluation. [Runner](run_acquisition_probe.py), [result](results/acquisition_cache_integrity_v1/result.json), predeclared question and interpretation in canonical strategy notebook S6. Unsuffixed bundle has 2,906 wholly nonfinite query rows and 13,464/13,464 wholly nonfinite plan rows. The suffixed bundle is finite, but 13,386/13,464 plan rows are the zero vector. Both score arrays match byte-for-byte. Missing row IDs/provenance prevent a strong pairing claim. These exports are ineligible for the proposed cross-model plan-transfer probe; this says nothing about the underlying models' capabilities. Sources preserved. Independent bit-level/schema audit e1011–e1012 upheld the scoped finding. Runner pins reviewed metadata/shape/byteorder; final scan ~1.23s.

## Strategy discovery opened (2026-09-13; NO MODEL RUN)

User authorized sustained autonomous strategy research at 19:45 UTC, including bounded informative CPU probes. Initial approach review separates contribution from deployment; donor removal is a branch, not a mandatory ladder. Definitions, an analytical access-ambiguity counterexample, extension obligations and primary source reading live in the canonical direction's strategy notebook. No empirical cross-model result, training or model calls. Initial added code apparatus/artifact is 0/0 (undefined ratio); theory/reading blocks are strategy work, not construction.

## Direction update — cumulative capability acquisition (2026-09-13; NO RUN)

User-directed documentation update, not an experimental result. The enduring native-mathematics philosophy is preserved; the current exploration direction is [cumulative capability acquisition](../theory/CUMULATIVE_CAPABILITY_ACQUISITION.md). Initial progression proposed A, acquire B, retain A, compose A+B, donor removal

and further donors. The subsequent strategy review makes donor removal a separate assimilation branch. No donors, tasks, thresholds or runs are selected. Earlier experiments remain historical supporting evidence, and old next-step language does not override [current state](../STATE.md).

Reverse chronological. Only gate-passed conclusions are stated as confirmed.
Program opened 2026-08-27; prior program's log is at `legacy/experiments/EXPERIMENTS.md`.

---

## Block 3 reading: length-only rival conditionally rejected at the 11-bin channel; the equal-length-comment reference scale is confounded (2026-09-06, ZERO-CALL READING, evidence gate REVISE)

Distance from claim: reading of existing audited evidence; no model calls.
Source: `results/svb_qwen3_composition_v2_multifiller/result.json`
(Qwen3-1.7B-Base, float32 CPU, 2026-09-04; sha256 898aff900864d3d2…).
Reading script `internal/q5_reading_multifiller.py` (git-ignored; sha256 e21aac988fcedd86…); exact rows in `internal/q5_reading_multifiller_out.json`.

**Interface of the archived table.** 24 roots (depth 4; x, y, z; values 1–8), surface A `# {var} is unchanged.` (5 tokens) and surface M `# Reassigning {var} now.` (7 tokens), three independent filler pairs (F_A: 5 tokens; F_M: 7 tokens; Qwen3 tokenizer, verified locally), eight two-suffix arms per root: AM, MA, AF_M, F_MA, MF_A, F_AM, F_AF_M, F_MF_A. Token counts and hence positions are matched by construction. Channel: 11-bin reduced law. No single-suffix arms, so the initial closeness of the input pairs is unknown; numerical floor assumed (deterministic replay was recorded for this stack in other runs, not in this table).

**The registered length-only rival (CR-15.10.6):** on identical input pairs, token-length- and position-matched H and filler F produce successor discrepancies differing by at most ε_R = 0.002. Read here with input pair (r·A, r·F_A) and successors M versus F_M (order 1), and input pair (r·M, r·F_M) with successors A versus F_A (order 2):

| Filler pair | Order 1: roots with | b_M − b_F | > 0.002 | median b_M / b_F | sign of b_M − b_F (positive roots) | Order 2: roots with | b_A − b_FA | > 0.002 | median b_A / b_FA |
|---|---|---|---|---|---|---|---|---|---|
| pair1 | 24/24 | 0.136 / 0.119 | 21/24 | 24/24 | 0.070 / 0.072 | | | | |
| pair2 | 24/24 | 0.034 / 0.033 | 8/24 | 24/24 | 0.077 / 0.052 | | | | |
| pair3 | 23/24 | 0.041 / 0.016 | 24/24 | 24/24 | 0.069 / 0.134 | | | | |

**Reference scale: between-filler spread (evidence gate: CONFOUNDED).** For each root, the three filler PAIRS give three values B(i,i) of the filler-successor discrepancy; each pair changes both the input pair's filler_A (i) and the successor filler_M. Their range mixes input-pair variation with successor variation (B(i,i) − B(k,k) = [B(i,i) − B(k,i)] + [B(k,i) − B(k,k)]) and does not isolate successor-filler variation; the needed off-diagonal

endpoints B(i,j), i ≠ j, are absent from the archive. The numbers below are therefore a mixed spread, not the scale of "an arbitrary equal-length comment on a fixed input".

| Order | median between-filler spread | median content-vs-filler deviation (pair1, pair2, pair3) | roots where content deviation exceeds the filler spread |
|---|---|---|---|
| 1 (successor M vs F_M) | 0.0975 | 0.0167, 0.0263, 0.0272 | 0, 0, 1 of 24 |
| 2 (successor A vs F_A) | 0.0840 | 0.0247, 0.0329, 0.0689 | 0, 2, 6 of 24 |

**Licensed sentence (evidence gate):** on the archived 24-root panel, using 11-bin immediate-read TV and assuming an adequate numerical floor, H and its matched successor filler violate the 0.002 length-only prediction on 24, 24, and 23 roots across three filler/input-pair variants; this conditionally rejects the restricted channel-specific rival (counts survive even the largest admissible guard, threshold 0.0022), but does not determine whether H is exceptional among equal-length successors. Under the locked interface the unqualified verdict is INCONCLUSIVE (floor unmeasured; revisions unpinned; single-suffix endpoints absent, so initial closeness unknown; successor W_H profiles incomplete; reduced-TV differences do not bound full-law differences; the affine rival cannot be tested without initial d_i). Order 2 compares surface A, which is neither the registered H nor N. The source preregistered the residual-order contrast, not this reading. Withdrawn: "H is not distinguishable from an arbitrary equal-length comment"; "content-specific H is disfavored"; "fillers vary more on identical inputs".

**What they do not support.** Initial-pair closeness (unknown; no single-suffix arms), so no tolerance-preservation or witness verdict; full-law statements (differences of reduced TVs do not bound full-law differences); any mechanism; any claim about the neutral comment N (not in this table).

**Program decision (evidence gate: AMENDED).** For any future panel: use several response-independently selected SUCCESSOR fillers on each identical input pair (fixed input, varied successor), with a prospectively specified comparison; three is a practical minimum, not a threshold this archive establishes, and hand-chosen fillers are not independent population samples. Generic readout sensitivity remains unexcluded, not confirmed. The deferred panel's discrimination against that rival is unestablished (no calibrated rival envelope, no reserved disagreement set). Decision-relevant: it changes which controls must be acquired (the missing fixed-input filler control) and prevents a misleading interpretation.

**Ruling (evidence gate):** stop zero-call rotation pending compute approval; the one prioritized acquisition is a small, time-capped CPU position-matched, full-law, eligibility-first panel on repaired strong-assert pairs spanning at least five task blocks: first measure empty and H profiles and reproducibility; if five robust W_H-close pairs exist, acquire the N/H successor profiles and three matched successor fillers on those same pairs; if coverage fails, stop without relaxing the threshold. Decision it answers:

do genuinely close real-model histories exist here, and which matched continuations separate them?

---

## Q4 reading: tolerance preservation under the neutral and heavy comments on the archived congruence panel (2026-09-06, ZERO-CALL READING, evidence gate REVISE)

Distance from claim: reading of existing audited evidence; no model calls. Source: `results/svb_qwen3_congruence/result.json` (Qwen3-1.7B-Base, float32 CPU, 2026-09-04; sha256 54d2b20afdf496db…). Reading script `internal/q4_reading_congruence.py` (git-ignored; sha256 806971037a766d7d…); exact rows in `internal/q4_reading_congruence_out.json`.

**Interface of the archived table (its original limits apply).** 24 cells (depth 4; variables x, y, z; outer values 1–8), three presentation pairs (a, a′) of the same semantic role, actions c0 = neutral comment `# No changes.` and c1 = heavy comment `# Reassigning {var} now.`, in forward order (surface then composer). Channel: the 11-bin reduced law (digits 0–9 + OTHER), NOT the full next-token law. Reduced-channel TV is a lower bound on full-law TV: a split at 11 bins establishes post-action FULL-LAW SEPARATION, but not a counterexample to full-law tolerance preservation (initial full-law closeness is unknown); closeness at 11 bins does not imply full-law closeness. $\tau = 0.01$ (the table's eps_eq); guard 1e-6 ASSUMED (this table has no replay or cached-versus-full data; CR-15.10.6 requires a measured floor; all counts survive at the minimum locked guard 2e-6).

CR-15.10 quantities per pair: D0 = TV(a, a′) after the surface (the W_0 question); DN = TV(a·c0, a′·c0); DH = TV(a·c1, a′·c1). A pair is W_0-close if $D0 \le \tau - \text{guard}$; a witness against tolerance preservation under action c is a close pair with $D_c > \tau + \text{guard}$.

| Pair type | W_0-close cells / 24 | Under N: witnesses, max DN on close | Under H: witnesses, max DH on close |
|---|---|---|---|
| strong_assert (`# State unchanged.` vs `# {var} is unchanged.`) | 24 (all x, y, z) | 0, 0.0064 | 23, 0.1162 |
| moderate_assert (`# Values preserved.` vs `# {var} is still intact.`) | 8 | 0, 0.0100 | 6, 0.0705 |
| misleading (`# Changing {var}.` vs `# Updating to a new value.`) | 1 | 1, 0.0678 | 1, 0.1180 |

Conditional numerical classifications at the archived 11-bin interface (evidence gate: under the actual locked CR-15.10.6 interface the verdict is INCONCLUSIVE, because the two surfaces of each pair have different token counts, 4/5, 4/6, 4/7, so composer and query positions are unmatched, and the numerical floor is unmeasured; the archive also lacks pinned tokenizer and model revisions and token IDs):

- strong_assert, N: preservation on 24 eligible task blocks (max DN 0.0064 < 0.01). Reduced channel, unmatched positions, assumed guard.

- strong_assert, H: **WITNESSED** (23 of 24 close pairs split; DH up to 0.116; the one non-witness is d4_x_1; d4_z_1 splits marginally at DH = 0.0121). Post-H full-law separation established; initial full-law closeness unknown.
- moderate_assert, N: preservation on 8 eligible task blocks (max DN 0.009990811, i.e. 9.19e-6 below τ, 7.19e-6 after the minimum locked guard: sensitive to the eventual measured floor; not "within the guard").
- moderate_assert, H: WITNESSED (6 of 8).
- misleading: 1 close pair (d4_z_1), split under both N (0.068) and H (0.118): WITNESSED for both actions; coverage 1, so no preservation statement is possible for this pair type.

**Licensed sentence (evidence gate):** on the archived unequal-position prompt panel, using 11-bin TV and an assumed numerical guard, N keeps all 32 initially close assert-type pairs below 0.01, while H separates 29; this supports candidate selection, not a matched-position full-law preservation verdict. Competence: on all 24 baselines and inspected roots the correct digit exceeds every other bin including OTHER (correct full-vocabulary top-one reads for those stored laws), which does not complete the deferred competence protocol. Conventional medians (strong_assert): DN 0.00449, DH 0.0821 (the script's original median was the upper-middle value; fixed).

**What they do not support:** full-law preservation under N (reduced channel); anything about carrier erasure; global moduli; any mechanism; reverse-order (composer-first) questions, which are a different family and were not read here; length-matched filler comparisons (the multifiller table uses different arms and was not read).

**Program decision (evidence gate: AMENDED):** prioritize strong-assert as the candidate family for a NEW position-matched, full-law eligibility panel; retain moderate-assert as a secondary boundary diagnostic; treat N-preservation and H-separation as W_0-level hypotheses. Do NOT replace the deferred panel: CRC-0 lacked W_H-close pairs, while Q4 supplies W_0-close pairs, a different eligibility criterion. At the minimum locked guard this archive supplies only three W_H-close pairs (strong d4_x_1; moderate d4_x_3, d4_z_1) over two task blocks, below the five-block requirement, and the subsequent N-then-H and H-then-H endpoints are absent. A full-law acquisition could eliminate initial eligibility altogether. Q4 is decision-relevant (candidate prioritization), not a discriminating experiment.
Never say: N preserves full-law tolerance; H refutes full-law preservation; replay-validated or matched-position witnesses; exact closure refuted; presentation information erased; forgetting safe indefinitely; H-specific semantics; these roots solve the locked W_H coverage requirement.

---

## CRC-0 witness reading: tolerance preservation under the heavy comment rejected on two pairs (2026-09-05, ZERO-CALL READING)

Distance from claim: reading of existing evidence; no new run.

Question (CR-15.10): is the immediate-response tolerance τ = 0.01 preserved under the heavy comment H ("# Reassigning {var} now.") on CRC-0's panel? The CRC-0 artifact (`results/crc_0/result.json`) stores only summaries (the runner computes but does not save the 36 × 13 response laws), so the enlarged-family closure test cannot be run from it. A one-sided witness check on the retained summaries is possible: `q0.all_cliques=true` proves every Q_0 split-event pair had d_0 < 0.01; a same-variable event with `worst_action="H"` and post-action full-law TV > 0.01 rejects preservation.

| Pair | Recorded input bound | Recorded post-H full-law TV |
|---|---|---|
| d4_y_3_P0 vs d4_y_3_P1 | < 0.01 | 0.0280 |
| d4_y_5_P0 vs d4_y_5_P1 | < 0.01 | 0.0271 |

**Licensed conclusion (Codex):** CRC-0's recorded full-law witnesses violate preservation of the 0.01 immediate-response tolerance under the heavy comment on two same-variable presentation pairs. This is a reading of existing numerical evidence, not a newly run test, and not a refutation of exact profile closure. Never say: "the immediate-read family is closed under the neutral comment"; "the model erased the presentation difference"; estimated global Lipschitz constants for N or H. Cheapest rival: ordinary lexical/position-dependent readout sensitivity. Design of the enlarged-family test $W_H=\{(\epsilon,\mathrm{read}),(H,\mathrm{read})\}$ and its decision rule: theory/CONTINUATION_REFINEMENT.md CR-15.10.5.

---

## Commit-Seal Certificate: INCONCLUSIVE; post-hoc contraction-premise failure on the fixed cube (2026-09-05, evidence gate REVISE)

Distance from claim: conditional (audit #39). Compute: one CPU retrain (130 s) + 0.3 s certificate + seconds of diagnostic. Design gate: analytic round 4; eligibility ruled by audit #40.

Question: does a TRAINED rung-1 sealed update cell (17,195 params) satisfy the CR-15.3 contraction certificate on a pre-fixed domain, giving a proved history-uniform overwrite bound for a learned artifact?

Protocol (fixed before the run): seed 11, sealed arm, identical training to rung 1; weights saved inside result.json before certification; domain D = [-H,H]^16 with H = max(1, ||m0||_inf) = 1; infinity norm; 128-bit outward interval arithmetic (mpmath.iv); no seed/norm/domain search.

| Step | Result | | | | |
|---|---|---|---|---|---|
| 1 interface | write(0), write(1), read; bypass zero; proposals enclosed to width 3e-38 | | | | |
| 2 domain | H = 1.0 ( | | m0 | | _inf = 0.22) |
| 3 invariance U_v(D) □ D | PASS (gates in [0,1], candidate in [-1,1], hull in box) | | | | |

| | | | | | |
|---|---|---|---|---|---|
| 4 contraction | Reported interval-Jacobian estimate 5.88; no contraction certificate. The row-maximum implementation required endpoint-safe comparison (fixed after the run, not rerun). | | | | |
| 5 fixed points | After 64 float32 iterations, reported interval residual bounds approximately 3.9e-8 and 2.7e-8. No certified location or uniqueness of a nearby fixed point. | | | | |
| 6 | Initialization and tube closure skipped: contraction was not established. | | | | |
| 7 reader | Reported reader estimate 78.3; not accepted as a certified bound because fixed offsets were computed outside interval arithmetic (fixed after the run, not rerun). | | | | |
| 8–9 | Calibration and usefulness skipped. The saved beta_hat=0.0 is a placeholder. No history-uniform response bound established. | | | | |

Diagnostics (not certificate): two-write accuracy 1.000; paired erasure max TV 1.4e-8 on the panel.

The registered certificate remains CERTIFICATE_INCONCLUSIVE. Separately, the post-hoc search reports interval-confirmed expansion for both writes on D=[-1,1]^16 in the infinity norm. The confirmation logic is sound and supports failure of that specific contraction premise. The reported 1.11 and 1.17 ratios are float32 search statistics. Expansion does not establish tightness of the global interval estimate. Exact witness coordinates and witness-specific provenance were not saved in this run (the runner now saves them).

On the eight factorial training cells, recorded two-write accuracy is 1.000 and maximum immediate-reader TV across obsolete-first-write counterfactuals is approximately 1.4e-8. These are finite-panel floating-point diagnostics, not evidence of carrier erasure or arbitrary-history fidelity. Jacobian norms 0.987 and 0.539 concern 64-step numerical candidates; they do not certify

fixed-point neighborhoods or switching between values. No behavioral overwrite failure is established.

**What it does not license:** any statement about address selection, two registers, unseen wording, seal advantage, any uniform guarantee for floating-point inference, or a pretrained model.

**Evidence gate (Codex): REVISE wording; no follow-up run on this cell.** Apparatus/model line ratio 451:79 = 5.71:1 in this lane; the certificate-search lane closes. Licensed sentence: on the eight factorial training cells, the saved run reports perfect two-write accuracy and maximum immediate-reader paired TV about 1.4e-8; its sound post-hoc interval-confirmation procedure reports contraction-premise failure for both writes on the unit cube in the infinity norm, while arbitrary-history behavioral overwrite remains unestablished and unrefuted.

Config: `config/commit_seal_certificate.json`. Result: `results/commit_seal_certificate/result.json` (weights inside). Runner: `run_commit_seal.py` (mode `single_cell_certificate`, flag `--witness-search`).

---

## WB-1: Write-Boundary Construction v1 (2026-09-04, COMPLETE — F4 / TASK TOO SIMPLE)

Distance from claim: 0. First constructed artifact.

Can an explicit overwrite mechanism produce compositional compression that a matched append-only carrier cannot? Two custom GRU models (~25K params, CPU), same fact-tracking task (2 registers × 4 values, 5-step write sequences, 32768 possible histories).

**Theory:** CR-10 through CR-14 in theory/CONTINUATION_REFINEMENT.md. Selective write-boundary laws (L1-L4), last-write normal form theorem, store cardinality bound |Q_H| ≤ |S| = 16. Five pre-declared falsifiers.

**Results:**

| | Overwrite | Append-only | | |
|---|---|---|---|---|
| Params | 21,338 | 27,844 | | |
| Val accuracy | 100% | 100% | | |
| | Q_H | | **16** (exact bound) | 20 |
| Compression | 2048:1 | 1638:1 | | |
| Store alignment | **1.000** | 0.750 | | |
| Gen len=7 | 100% | 100% | | |
| Gen len=10 | 100% | 100% | | |
| Gen len=15 | 100% | 99.9% | | |

**Verdict: F4 — both compress; task may be too simple.** The append-only GRU with attention learns to extract last-write information from its log almost as well as the hard-masked register file. Quotient ratio 1.25x < 1.5x threshold.

**What survives:**

1. Overwrite model hits the theoretical bound EXACTLY (16 classes, perfect store alignment). The normal form theorem is confirmed by construction.
2. Append-only model leaks 25% of history (20 classes, 0.750 alignment). For 4 of 16 store states, different write histories produce different behavior. The

architectural difference IS visible, just not dramatic on this task.

3. Both generalize perfectly to 3× longer sequences on simple fact-tracking.

**What F4 means:** Simple fact-tracking (last-write recall) is too easy — a GRU with attention can learn it without needing an explicit overwrite boundary. The decisive test requires tasks where the answer depends on RELATIONSHIPS between registers or on compositional operations, not just individual register reads.

**Next:** WB-2 — compositional task with cross-register operations.

---

## CEG-1: Causal Erasure Graph v1 (2026-09-04, COMPLETE — REVISE / NO_INTERFACE)

Distance from claim: 0.

Where does dead information live when a transformer retains overwritten facts? Custom 4D attention mask interventions on Qwen3-1.7B-Base (eager attention, full forward passes, no KV cache). 16 fixed-slot histories × 4 identifier sets, 6 intervention arms. 914 CPU forwards, 259s.

**Verdict (Codex Evidence Gate, audit #38): REVISE.** The original RELAY headline does not pass. Competence preflight failed (83.6% < 95%); binding design required NO_INTERFACE. RELAY-CUT Δ=0 is tautological (downstream positions see only pair-identical tokens). The residual under QUERY-CUT is channel-nonspecific.

**Licensed sentence (Codex, verbatim):** In this fixed-slot Qwen3-1.7B-Base panel, changing overwritten assignments altered normalized binary response profiles, and after direct query-to-early-span attention was cut an indirect, identifier-consistent excess over matched dummy cuts remained (mean max-channel TV excess 0.101); however, the residual was channel-nonspecific and observed after a failed competence preflight, so CEG-1 identifies bounded attention-mediated context dependence, not semantic relay of dead information in competent computation.

**Apparatus validation:**

- Fixture: OPEN mask reproduces standard inference exactly (TV=0.00)
- Mask effectiveness: extreme cut TV=0.856 (masks change output)
- Isochrony: 0 failures across 256 rendered histories
- Tokenization: clean concatenation for all histories

**Key results (post-audit):**

- OPEN Δ=0.406 (accuracy 83.6%; r0=71.9%, r1=95.3%)
- QUERY-CUT Δ=0.194 (accuracy 64.1%; channel specificity disappears)
- RELAY-CUT Δ=0.000 (accuracy 100%; tautological by mask design)
- LIVE-CUT Δ=0.934 (positive control)
- SYNCHRONIZER Δ=0.267 (accuracy 89.1%)
- Dummy OPEN Δ=0.105 (accuracy 96.1%)
- Paired excess (QUERY-CUT − DUMMY-CUT): 0.101, bootstrap CI [0.050, 0.152]
- Target vs orthogonal excess: 0.062 vs 0.061 (nonspecific)

**Audit corrections (adopted verbatim):**

1. RELAY-CUT=0 is a tautology: downstream positions see pair-identical inputs.

2. "52/48 pathway split" used arm-specific channel maxima and is invalid.

Dummy-adjusted ratio is 33/67.

3. Under QUERY-CUT, register-specific effect disappears: target and orthogonal channels show equal excess. Residual is broadcast context sensitivity.

4. Four "renderings" = one syntax with four identifier pairs (name robustness, not template generalization).

5. SYNCHRONIZER rejects one string, not synchronization or irreversibility.

6. Design omitted target/orthogonal effects, CDFs, clustered bootstrap, full-vocab accuracy, replay noise, and model revision binding.

7. Mean erasure ratio (−24%) is an unstable ratio statistic driven by 3 extreme outliers at small OPEN denominators; "blocking direct access amplifies relay" is not identified. Ratio of arm means shows 52.3% reduction.

8. Measurement-to-artifact ratio: 506:0 (infinite).

**Never say:** "Dead information persists through attention relay into live-write representations; roughly 48% is relayed, and the failed synchronizer shows that this relay is irreversible."

**Real non-tautological finding:** RELAY-CUT raises accuracy from 83.6% to 100%. A hard attention reset at the first live write erases earlier interference and recovers every binary answer. This is a strong positional effect in the tested interface; it does not by itself prove that the append-only carrier lacks an endogenous behavioral overwrite boundary (audit #39 correction, 2026-09-05).

**Next:** CEG-1R (terminal pretrained-Qwen localization test) or close Qwen path.

Config: `config/ceg_1.json`. Result: `results/ceg_1/result.json`.

---

## CRC-1: Overwrite/Erasure Semigroup (2026-09-04, COMPLETE — INVALID / BOUNDED NEGATIVE)

Distance from claim: 0.

Does a transformer garbage-collect overwritten facts, or do dead histories continue haunting its future behavior? Codex Architecture Theorist design. Two binary registers (a,b), 32 roots (8 per final store in $\{0,1\}^2$), 4 literal actions (a=0, a=1, b=0, b=1). Task-aligned {0,1} normalized binary observer (primary), full-vocab diagnostic. Exhaustive words through length 2. Cross-fitted 2-fold closure. Non-oracle NN baseline. Algebraic relation verification (idempotence, absorption, commutation).

1508 forwards, 357s CPU, Qwen3-1.7B-Base float32.

**Preflight**: Tokenization clean. Competence 56/64 = **87.5%** — below 95% threshold, rendering experiment INVALID per preregistered criteria.

**Q_0**: 31 classes (task-channel). Store purity 1.0. Min TV = 0.011.

**Q_1**: **32 classes — identity partition.** Zero compression at every tolerance level (0.005–0.05). Min D_1 = 0.099, far above any reasonable eps. No multi-member classes. Every root is behaviorally distinct under even the coarsest {0,1} observer.

**Q_2**: 32 classes. Tower trivially stable. Q_1→Q_2 frag = 0.000.

**Closure (cross-fitted)**: 52/256 = 0.203. (Bug fix: halves trained separately, test roots assigned to nearest train class.)

**Algebraic relations**: Overall 25.9% pass rate (need >=95%).

- Idempotence: 37.9% (mean TV=0.054). a=0;a=0 □ a=0.
- Absorption: 20.7% (mean TV=0.102). a=0;a=1 □ a=1. Dead writes visible.
- Commutation: 19.1% (mean TV=0.110). a=u;b=v □ b=v;a=u. Not independent.

**Baselines**: NN (non-oracle, D_1-selected) TV ≈ 0.10. Quotient = 1.0 (all singletons). Store-matched = 1.0 (all held out in LOSO).

**Mode F**: TV = 1e-6. Cache perfectly faithful.

**Verdict**: INVALID (competence below 95%). But even ignoring validity: comprehensive FAIL — identity partition, massive algebraic relation failure, no compression at any tolerance. The model does NOT forget overwritten facts; dead history remains operationally visible.

**Bug fixes from CRC-0**: (1) Closure now cross-fitted (2-fold). (2) NN baseline selects neighbor by D_1 metric, not oracle.

**Binding finding**: Dead histories haunt the transformer. a=0;a=0 does not behave like a=0. Order of independent register writes matters. The model's state is path-dependent even for semantically equivalent programs.

Config: `experiments/config/crc_1.json`. Runner: `experiments/run_crc_1.py`. Results: `experiments/results/crc_1/result.json`.

---

## CRC-0: Continuation-Refinement Calculus (2026-09-04, COMPLETE — FAIL / NO COMPRESSION)

Distance from claim: 0.

Decisive test of the CRC framework: does Qwen3-1.7B-Base admit a compact predictive refinement tower on the SVB task family? Codex-designed (design gate: REVISE then GO). Full next-token distribution (151,643 vocab), not 11-bin projection. 3 typed actions (N=neutral comment, H=heavy comment, R=reassignment), 36 roots (3 variables × 4 values × 3 presentation templates), exhaustive words through length 2 (13 per root). Clique-verified equivalence classes. Cross-fitted transfer testing. Multi-tolerance stability.

544 forwards, 210s CPU, Qwen3-1.7B-Base float32.

**Preflight PASS**: Tokenization clean. Competence 36/36 = 100%.

**Q_0**: 33 classes (3 pairs merged at immediate response: x_1_P1≡y_1_P0, y_3_P0≡y_3_P1, y_5_P0≡y_5_P1). Some presentation equivalence at horizon 0.

**Q_1**: 36 classes — **no compression**. Every root distinct. All Q_0 pairs split. Min pairwise D_1 = 0.0165. Witnesses: R splits cross-var pair (TV=0.111), H splits presentation pairs (TV~0.028).

**Q_2**: 36 classes. Tower stabilizes trivially. Q_1→Q_2 frag = 0.000.

**Closure**: vacuous (0/0, no multi-member Q_1 classes). Coverage: 0%.

**Transfer**: FAIL all folds (all singletons — no class members to predict from). Text baseline TV = 0.039–0.057; nearest-neighbor = 0.016–0.031.

**Mode F**: TV = 7.0e-7. Cache perfectly faithful.

**Verdict stability**: Same FAIL at eps = 0.005, 0.01, 0.02.

**VERDICT: FAIL — no compression (Q_1 ~ one per state).**

**What we learned:**

1. The model maintains 36 distinct behavioral states (every var×val×pres triple
produces a unique full-distribution signature surviving action application).
2. Q_0 compression exists (33/36) but shatters after one action.
3. Min D_1 = 0.0165, just 65% above tolerance — model is ALMOST compressible.
4. The CRC apparatus works cleanly; the model doesn't compress on this task.

Config: `config/crc_0.json`. Results: `results/crc_0/result.json`.
Runner: `run_crc_0.py`. Codex design gate: `.codex_crc_design.txt`.

---

## Curvature Control: Isochronous Position-Matched (2026-09-04, COMPLETE — FAIL / LINE CLOSED)

Distance from claim: 0.

Confound-killing control for the d3→d4 curvature signal. Codex-designed
(session 01a06cea), implementing exact token-position matching (two padding
families), varied inner literals (repeat8/repeat9), two shadow readouts (sd8/sd9),
6 template instances (2 train / 4 holdout), 5 surface pairs (2 train / 3 holdout),
position-gain null model (OLS), and 24-call deterministic replay calibration.

768 model calls, 249s CPU, Qwen3-1.7B-Base float32.

**G0 PASS**: All token counts verified, all boundaries clean.
**G1 PASS** (threshold 0.80): 85.4% accuracy. repeat8 profile causes digit-8 competition.
**G2 PASS**: Mean assert-minus-mislead gap = 2.16 nat.
**G3 PASS**: Zero replay noise (deterministic CPU).
**G4 FAIL**: All 4 position-gain null models fail holdout validation (train $R^2$=0.82-0.96,
holdout MAE=0.16-0.25 > 0.05 threshold). Scalar position gain doesn't transport.
**G5 FAIL**: 9/10 checks pass. Mean κ = -0.542 nat, CI [-0.698, -0.362], 12/12 blocks
negative. Only failure: pad_diff_ok — PAD_BARE (-0.377) vs PAD_WORD (-0.706), diff
0.329 > 0.10 threshold. Individual cells: 93/96 negative, 3 PAD_BARE cells positive.
**G6 FAIL**: No valid null models from G4.

**Codex adjudication: Option (b) — real but qualified, LINE CLOSED.**

- The behavioral interaction is real but padding-sensitive, not intrinsic curvature.
- G5 is a genuine refutation of the preregistered invariant claim.
- The authorized "exactly one control round" has been spent and did not pass G4-G6.
- Most of κ comes from ASSERT becoming more beneficial at d4 (ρ_A=+0.375), not
just MISLEAD strengthening (ρ_M=-0.167).
- "Still the R^n trap": scalar logit differences and OLS, not native math.

**Transferable residue:**

- Position matching did not produce representative-invariant magnitude.
- Scalar position-gain law fails to transport across template families.
- The response is presentation-conditioned (padding content modulates magnitude).

**Licensed sentence:** In this configured Qwen3-1.7B SVB control, the held-out

d3-to-d4 change in the MISLEAD-minus-ASSERT correct/shadow logit contrast was
negative on all 12 template-by-surface block averages under two exact-position
padding controls (mean −0.542 nat; clustered CI [−0.698, −0.362]); its magnitude
differed substantially between bare and word padding, and the registered
position-gain null did not validate, so this is a padding-sensitive behavioral
interaction rather than confirmed intrinsic curvature.

Config: `config/curvature_control_qwen3.json`.
Results: `results/curvature_control_qwen3_v1/result.json`.
Runner: `run_curvature_control.py`. Codex adjudication: `codex_curvature_control_adjudication.txt`.

---

## Curvature Test: Depth × Suffix Interaction (2026-09-04, COMPLETE — SUB_THRESHOLD / CONTROL REQUIRED)

Distance from claim: 0.

Codex-designed interventional curvature test. κ = [z(d_high, MISLEAD) - z(d_high, ASSERT)]
 [z(d_low, MISLEAD) - z(d_low, ASSERT)]. Under additive logit model κ=0.

288 calls, 98.3s CPU. 3 variables × 8 values × 3 depths × 3 suffixes.

Split-half validation: train on {x,y}, hold out {z}.

**Gate 0 (Competence):** PASS — 100% accuracy (72/72).

**d2→d3:** Heterogeneous (x positive, y negative — cancel in aggregate). Not null; not coherent.

**d3→d4:** κ=-0.284 nat for the tested pair, 24/24 cells same sign.

Sub-threshold: 0.28 < 0.5 pre-registered gate. SNR gate also never computed.

**Codex adjudication (REVISE / CONTROL REQUIRED):**

- Descriptively nonzero (17% of suffix contrast, exp(-0.28)=0.75). Scientifically sub-threshold.
- Gate 1b cross-surface check: only 65.5% of 168 (assert,mislead) pairs show negative κ.

MISLEADING surfaces range −0.235 to +0.155 (mixed signs). NOT representative-invariant.

- Position is the strongest rival: absolute token position changes with depth (38→58→79).
- 24 deterministic cells ≠ 24 independent replications.
- Half the separation comes from ASSERT becoming MORE beneficial at d4.

**What it advances:** The fixed suffix contrast is context-dependent and cannot be
represented by the simplest globally additive logit-shift model. Candidate obstruction
and falsifier generator, not yet a law.

**Next:** One confound-killing control round (position-matched, token-matched,
multi-surface, varied shadow). If residual curvature doesn't survive, close this line.

Config: `config/curvature_qwen3.json`. Results: `results/curvature_qwen3/result.json`.
Runner: `run_curvature.py`.

---

## S3 Permutation Composition (2026-09-04, COMPLETE — MODEL_CANNOT_COMPOSE)

Distance from claim: 1 (task family competence test).

Codex-designed experiment testing whether Qwen3-1.7B-Base computes S3 permutation
group composition with genuine algebraic structure. 36 ordered pairs (6x6),
6-way candidate scoring via teacher forcing, 4 pre-registered gates.

**Result:** Gate 1 FAIL (4/36 correct, threshold 34). Model has degenerate c021 output bias — predicts the same permutation regardless of input. All 4 "correct" predictions are lucky matches. Gate 2 also FAIL (additive null beats model).

**What we learned:** Qwen3-1.7B-Base cannot trace Python function calls for tuple permutation operations. This is a COMPETENCE failure, not an algebra failure. The task is beyond the model's code-tracing capability at 1.7B parameters. Future composition tests must use tasks within the model's proven competence (e.g., SVB-style variable retrieval with simple single-digit output).

Config: `config/s3_qwen3.json`. Results: `results/s3_qwen3/result.json`.

---

## Congruence Test (2026-09-04, COMPLETE — NO_CONGRUENCE)

Distance from claim: 0.

768 calls, 218s CPU. Codex-designed decisive test for native algebra.

**Purpose:** Test whether behavioral equivalence (surfaces with matching δ_L) is preserved under suffix composition — the algebraic congruence property.

**Design:** 3 equivalence pairs (cross-role surfaces with δ_L diff < 0.006), composed with 2 composers (neutral: "# No changes.", heavy: "# Reassigning {var} now."), in both orders (a;c and c;a), across 24 contexts.

**Results:**

| Pair | Single TV | Neutral comp | Heavy comp | Ratio (heavy) |
|---|---|---|---|---|
| strong_assert | 0.006 | 0.004-0.011 | 0.019-0.074 | 3.4-13.2 |
| moderate_assert | 0.013 | 0.008-0.012 | 0.038-0.048 | 3.0-3.8 |
| misleading | 0.025 | 0.023-0.043 | 0.051-0.064 | 2.1-2.6 |

**Verdict:** NO_CONGRUENCE. Behavioral equivalence holds in isolation but is destroyed by composition with semantically heavy suffixes. The δ_L-based quotient is NOT an algebraic congruence.

**Additional finding:** δ_L is predicted by text features at $R^2$=0.88.
Dominant features: has_preserve (-1.86), is_rewrite (+0.71), has_change (-0.57).

Config: `experiments/config/svb_qwen3_composition_v2.json` (shared)
Results: `experiments/results/svb_qwen3_congruence/result.json`
Runner: `experiments/run_congruence.py`

---

## Quotient Closure + Held-Out Prediction (2026-09-04, COMPLETE — K_s DEAD)

Distance from claim: 0.

Pure analysis on Gate 1b data (3,384 obs, no new model calls).

**Purpose:** Test if K_s (3×3 stochastic matrix on CLR simplex) generalizes on held-out data and beats baselines.

**Results:** K_s: 0/43 surfaces beat ANY baseline. Mean err 0.290 vs best baseline (logit-shift) 0.039. The actual operator is a constant logit shift. Shadow logit shift δ_L is depth-invariant (CV=0.036 ASSERT). Response collision closure 100% for ASSERT roles. Cross-role transfer fails.

Runner: `experiments/analyze_quotient_closure.py`

---

## Gate 2 v2 Multi-Filler Robustness (2026-09-04, COMPLETE — POSITION_WITH_NONLINEAR_GAIN)

Distance from claim: 0.

288 new calls (filler pairs 2 & 3), reusing 192 from v2 (AM/MA + pair 1).

3 independently selected token-matched filler pairs. 2.4 min CPU.

**Purpose:** Test whether residual order contrast (the correct statistic) is

consistent across filler pairs and survives scalar gain fit.

**Results:**

| Filler pair | Resid. median | Gain-fit median | Contexts > 0.01 (gain) |
|---|---|---|---|
| pair1 | 0.067 | 0.007 | 6/24 |
| pair2 | 0.040 | 0.003 | 0/24 |
| pair3 | 0.089 | 0.009 | 10/24 |

Cross-filler correlations: pair1-2 r=0.82, pair1-3 r=0.92, pair2-3 r=0.69.

**Verdict:** POSITION_WITH_NONLINEAR_GAIN. The order effect is real, consistent

across fillers, but fully absorbed by a scalar gain fit. Position with

context-dependent magnitude is the correct explanation. Gate 2 composition is

a structured negative.

Config: `experiments/config/svb_qwen3_composition_v2_multifiller.json`

Results: `experiments/results/svb_qwen3_composition_v2_multifiller/result.json`

Runner: `experiments/run_multifiller.py`

---

## Gate 2 v2 — Filler-Based Noncommutativity (2026-09-04, CLOSED — subsumed by multi-filler)

Distance from claim: 0 (this IS the native math claim).

216 calls, 8 arms per context, 24 contexts (3 vars x 8 vals), depth 4.

135s CPU on Qwen3-1.7B-Base. Deterministic (seed 42).

**Purpose:** Test whether suffix operators A and M compose non-trivially

(noncommutatively) after absorbing all additive position/recency effects.

Uses Codex-designed token-length-matched neutral fillers and algebraic

subtraction: predicted_phi(AM) = phi(AF_M) + phi(F_AM) - phi(F_AF_M).

**Design:** 8 arms: AM, MA, AF_M, F_MA, MF_A, F_AM, F_AF_M, F_MF_A.

A = "# {var} is unchanged.\n" (5 tok), M = "# Reassigning {var} now.\n" (7 tok).

F_A = "# Code block follows.\n" (5 tok), F_M = "# Looking at the next part.\n" (7 tok).

**Results:**

| Metric | Value |
|---|---|
| Direct TV(AM,MA) median | 0.068 |
| Direct TV(AM,MA) mean | 0.072 |
| Excess (prob-space) mean | 0.033 |
| Excess (log-ratio) mean | 0.038 |

| | |
|---|---|
| Gate 1 (direct > 0.01) | PASS |
| Gate 2 (excess > 0.01) | PASS |
| Verdict | NONCOMMUTATIVE_CONTROLLED |

Per-variable (log-ratio): x direct=0.040/excess=0.038, y direct=0.112/excess=0.026,
z direct=0.063/excess=0.050.

**Codex evidence gate: PROVISIONAL.** Gate 1 (direct order) strong. Gate 2 (excess) disputed: implementation computed armwise prediction error, not pre-registered residual order contrast. Filler-predicted order vectors align (cosine=0.996) but over-predict magnitude. Nonlinear position gain is the strongest rival. Repair: frozen residual-order statistic, multi-filler robustness, held-out prefix family.

**What we learned:**

1. Direct order effect is robust (median TV=0.068, all 24 contexts above threshold).
2. Filler-based controls confirm direction but not independence from position.
3. Nonlinear position gain (scalar fit) reduces 18/24 contexts below threshold.
4. K_A correction rate L->C is depth-invariant at ~0.72 (separate finding).

Config: `experiments/config/svb_qwen3_composition_v2.json`
Results: `experiments/results/svb_qwen3_composition_v2/result.json`
Runner: `experiments/run_composition_v2.py`

---

## Gate 2 v1 — Operator-Level Composition (2026-09-04, COMPLETE — RECENCY_DOMINATED)

Distance from claim: 0.

504 calls, 4 pairs (2 cross-role, 2 same-role controls), depth 4. 550s CPU.
Verdict: RECENCY_DOMINATED. Cross-role TV median=0.081 < same-role max=0.130.
Codex correction: same-role controls are the wrong null model.

Config: `experiments/config/svb_qwen3_composition.json`
Results: `experiments/results/svb_qwen3_composition/result.json`

---

## Gate 1b — Confound Control (2×2 ANOVA + lumpability + surface equivalence) (2026-09-04, COMPLETE)

**Interpretation qualification, 2026-09-13:** the content factor is the tested assertion-versus-misleading text contrast, not an intervention on meaning with every surface feature controlled. Its 6.3× ratio excludes variable mention alone on this panel. Historical "proves" and native-coordinate language below is also superseded by the later failed composition and scalar logit-bias findings.

Distance from claim: 0 (this IS the native math claim).

3,384 calls across 8 roles (ASSERT, ASSERT_VAR, MISLEADING_ASSERT, MISLEADING_ASSERT_NOVAR, REWRITE, OBSERVE, BOUNDARY, BASELINE), 3 vars, 8 outer_values, 3 depths (2-4). ~100 min CPU on Qwen3-1.7B-Base.

**Purpose:** Disentangle content vs variable-mention effects from Gate 1.

Test whether K_u is a well-defined operator (lumpability) and whether surfaces within the same semantic class are interchangeable (equivalence).

**Results:**

| Analysis | Verdict | Key number |
|---|---|---|
| 2×2 ANOVA | CONTENT DOMINATES | 6.3x (content +0.092 vs var-mention +0.015) |
| Lumpability (F8) | STRONG | R2 = 0.79–0.98 across all roles |
| Multiplicative char CV | HIGH | Within-class CV 0.33–0.51 |
| Surface equiv (class A) | 1 pair passes | max TV = 0.009 |
| Surface equiv (class M) | 0 pairs pass | best max TV = 0.022 |
| K_a vs logit-bias | INCONCLUSIVE | No holdout for cross-validation |
| R-preservation | Tentatively K_a | ASSERT dR=−0.007, MISLEADING dR=+0.003 |
| F6 Baseline | MARGINAL | +0.006 TV over cheap features |

**What we learned:**

1. The content/misleading distinction is real and dominant (6.3x over var-mention).
2. The (C,L,R) simplex IS approximately the right coordinate system — lumpability proves K_u is well-defined on it.
3. But the mapping surface→operator is finer than semantic role. Different surfaces within the same class produce different K_u operators (CV 0.33–0.51).
4. Gate 2 has one validated class-A pair but zero class-M pairs at eps_eq=0.01.

Runner: `experiments/run_semantic_descent.py`. Config: `experiments/config/svb_qwen3_gate1b.json`.
Result: `experiments/results/svb_qwen3_gate1b/result.json`.
Analyzers: `analyze_multiplicative_character.py`, `analyze_lumpability.py`, `analyze_surface_equivalence.py`. Ledger: `gate1b_confound_control`.

---

## Decode-versus-full diagnostic — faithful query continuation localized (2026-09-03, COMPLETE; INTERPRETATION CORRECTED)

Distance from claim: 2 (runtime-instrument validation).

Four fixed 27-cell Falcon-H1 conditions compare:

- prefix prefill followed by the 12-token query in one multi-token cached call;
- prefix prefill followed by the same query one token at a time;
- the same complete text in one no-cache forward pass.

**Results:** condition-mean TV between tokenwise cached and full-forward 11-bin response laws was `5.269e-7` to `1.2107523675e-6`. Multi-token cached versus full-forward TV was `0.546–0.885`. The prefetched `s1` condition reduced mean correct-digit probability relative to `s0` at both tested depths.

**Licensed interpretation:** the multi-token cached query path changes the tested hybrid runtime's response law, while tokenwise cache advancement agrees closely with full-forward execution on this projected aggregate diagnostic.

**Limits:** the runner inserts `s0`/`s1` before prefill and changes only query chunking, so it does not rerun the original prefix-cache → suffix-plus-query boundary. The result JSON retains condition aggregates rather than per-cell response laws. It does not establish full-vocabulary equivalence, architecture

separation, an attention-versus-SSM mechanism, continuous-vector reasoning,

efficiency, or future acquisition.

Runner: `experiments/verify_svb_decode_mode.py`. Result:

`experiments/results/svb_decode_verification.json`. Audit correction:

`svb_decode_verification_audit_correction` in the append-only ledger.

---

## Execution-Mode Invariance — four modes, 9 core words (2026-09-03, COMPLETE: ALL DIVERGENT)

Distance from claim: 2 (measurement of the artifact).

Tests whether the suffix action algebra is invariant across execution modes

of the Mamba-Transformer hybrid. Codex design gate: CONDITIONAL GO.

**Four modes:**

- L (legacy joint): prefix cached → [word + query] — reproduces existing evidence
- W (whole then query): prefix cached → [word] → [query] — isolates query boundary
- G (generator by generator): prefix cached → [gen1] → [gen2] → ... → [query]
- F (full text): [prefix + word + query], no cache — tests theory's claimed Z

**Pre-registered:**

- Mode tolerance: eps_mode = max(0.01, 5 * delta_replay), calibrated from replay
- Defect re-adjudication per mode (BAND2, SAT3, right-continuation) at eps_TV=0.06
- 100K bootstrap for mode comparisons, 10K for defects, seed 42
- A post-hoc simultaneous-band artifact was produced but is nondecision-grade:

its maximum statistic was uncentered and cannot validate the independent intervals.

**Decision rules:**

- L≠W: query-boundary artifact in existing evidence
- L=W but W≠G: generator packaging matters, no partition-independent action
- L=W=G but ≠F: cached-state action system valid, Z = cache states not texts
- All agree: execution-mode blocker clears

**Results (2079 calls, 5568s CPU, Stage 1 only — Stage 2 not triggered):**

- Token identity gate: 420 checks, zero mismatches.
- Replay calibration: delta_replay=0.0 (perfectly deterministic), eps_mode=0.01.
- Consistency check: Mode L CPC bit-for-bit identical to band2 historical data.
- All 54 word×mode-pair point comparisons exceed the registered mode tolerance

under the original reducer. The committed simultaneous reanalysis is not a

valid confidence-band repair and carries no additional decision weight.

- L vs W: TV 0.33-0.42 — MASSIVE query-boundary artifact.
- W vs G: TV 0.05-0.18 — generator packaging changes state.
- All vs F: TV 0.36-0.78 — cached vs non-cached fundamentally different.
- Mode F collapses ALL defects to NEAR (TV<0.016). The algebra vanishes

without KV caching.

- Defect re-adjudication: L matches historical. W shifts some edges. G makes

all FAR. F makes all NEAR.

- Spearman structural invariance: L/W/G moderately correlated (rho 0.54-0.69),

F uncorrelated with all (rho -0.007 to 0.189, p>0.27).

**Interpretation (REVISED 2026-09-03):** Source inspection localizes a

HuggingFace implementation gap: Falcon-H1 `torch_forward` starts the Mamba SSM

layers from ZERO state for multi-token continuation (line 819:
`previous_states = torch.zeros_like(states[:, :1])`). Both
`mamba_chunk_scan_combined` and `causal_conv1d_fn` accept `initial_states`
parameters; this path does not pass them for `seq_len > 1`.

Verification: one-shot vs two-shot TV = 0.118, max logit diff = 6.527.
One-shot vs single-token decode TV = 0.000000 (exact match).
Cross-prefix two-shot response convergence TV = 0.794, consistent with lost
direct recurrent history but not proof of zero prefix influence through attention.

The affected path omits direct cached recurrent and convolutional history, and
its registered response law differs sharply from full-forward and tokenwise
execution. This makes the recorded Falcon suffix algebra non-claim-bearing as
faithful state dynamics; it does not prove that the omission causes every
suffix contrast. All prior Falcon-H1 SVB/suffix experiments used this path.
SVB-Qwen3 does not use the Falcon/Mamba branch.

**Status:** COMPLETE runtime diagnosis; no architecture or mechanism claim.

---

<details>
<summary>Historical affected-runtime algebra experiments — superseded</summary>

> ***Terminal correction:** The following measurements were made through the defective multi-token cached continuation. Their arithmetic remains a runtime diagnostic, but their native-object, composition, and faithful-model interpretations are not claim-bearing.*

## Historical Right-Continuation Test (2026-09-03)

Distance from claim: 2 after runtime audit.

Tests whether length-3 words are genuine terminal elements (right absorption)
or merely single-step near-returns. 4 arms (CPC, CPCC, PCPP, CPCPC), 27 cells,
135 forward passes, 2654s. TV metric, eps_TV=0.06.

**Results:**

- CPC absorbs C? TV(CPC,CPCC)=0.060 [0.051,0.067] → INCONCLUSIVE
- PCP absorbs P? TV(PCP,PCPP)=0.072 [0.066,0.077] → REFUTE (LB>ε)
- Len-5 SAT? TV(CPCP,CPCPC)=0.064 [0.056,0.072] → INCONCLUSIVE
- CPC terminal? TV(CPC,CPCPC)=0.099 [0.086,0.110] → REFUTE

Key findings:

- The monoid does NOT collapse to a finite quotient. Words keep evolving past length 3. CPCPC is genuinely different from CPC (TV=0.099, well above ε).
- H-SAT3 near-return (CPCP≈CPC) is a one-step property, not genuine saturation.
- Sigma degrades monotonically with suffix length: CPC=0.486 → CPCC=0.439 → CPCPC=0.393. Performance worsens, contradicting terminal-zone interpretation.
- PCP definitively does NOT absorb P (LB=0.066 > ε_TV).
- CPC absorbing C remains inconclusive (point estimate exactly at threshold).
- CPC arm bit-for-bit consistent with band2 run (consistency check PASS).

Historical diagnostic object: a truncated response-labelled continuation table
for the affected runtime.

---

## Historical Band2 Decisive Test (2026-09-03)

Distance from claim: 2 after runtime audit.

Tests three competing hypotheses after H-LRB refutation:

H-BAND2 ((CP)^2~CP), H-SAT3 (CPCP~CPC), H-GEN-IDEM (all grow).

12 arms, 27 cells, 351 forward passes, 925s. TV metric, eps_TV=0.06.

**Results:**

- H-BAND2 REFUTED: TV(CPCP,CP)=0.107 [0.098,0.117], TV(PCPC,PC)=0.122 [0.108,0.136]
- H-SAT3 BEST FIT, FORMALLY INCONCLUSIVE: CP arm passes (TV=0.050, UB=0.056 ≤ 0.06); PC arm borderline (TV=0.052, UB=0.064 > 0.06). Registered joint rule requires both.
- H-GEN-IDEM REFUTED: SAT3(CP) UB <= 0.06

Key findings:

- Generator idempotence does NOT propagate to products: CPP-CP formally inconclusive (CI [0.056,0.070] crosses ε_TV); PCC-PC marginal (LB=0.062). Not a congruence.
- Branch coalescence: TV(CPC,CPP)=0.039 — CP's children converge, but both remain separated from CP itself. NOT right absorption.
- Overlapping maximal cliques at ε=0.06, not a single equivalence class.
- Exploratory contraction (unregistered): C distance-reducing (mean r=0.67), P mixed (mean r=1.03). Post-hoc, incomplete pair selection.
- No semigroup variety licensed. The affected-runtime table can be represented as a truncated response-labelled continuation automaton.

Fidelity: cached-vs-full TV=0.533; all conclusions scoped to cached-continuation.

Codex evidence gates (two rounds): REVISE verdicts adopted. LRB-era defects reproduce exactly.

Runner: experiments/run_band2_decisive.py. Results: experiments/results/band2_decisive/.

Predictions frozen: commit f95dfb7.

---

## Historical Suffix Action Algebra construction (2026-09-03; interpretation superseded)

Distance from claim: 2 after runtime audit — formal diagnostic, not native-model evidence.

Files: `theory/closed/SUFFIX_ACTION_ALGEBRA.md`, `theory/suffix_algebra.py`, `theory/frozen_predictions_CP.txt`.

Ledger: `suffix_action_algebra_construction`.

**What was built:**

- SVB transition world as D1 specialization (raw states, suffix actions, 11-bin response laws)
- Behavioral places Q = Z/~ (D5 quotient by future-response identity)
- Suffix transition monoid S = A*/≡_Q (behaviorally distinct suffix sequences)
- Defect measures (idempotence I, residuation R, commutator N) with binding thresholds
- Accessibility languages L_θ(q) and directed cost c_θ(q)

**Hypotheses stated:**

- H-LRB: S is approximately a left-regular band ($a^2 \approx a$, $aba \approx ab$)
- H-Truth: suffix actions conjugate under truth-reversal involution J

**Theorem proved:** Truth-congruence reversal obstruction (on raw states Z).

**Symbolic normalizer (frozen predictions before experiment):**

- 2 generators {C, P}: 5 normal forms, 2 decisive predictions (CPC ≈ CP, PCP ≈ PC)

- 4 generators {C, P, U, V}: 65 normal forms, 13 decisive predictions

**Codex audit:** FAIL → 7 corrections adopted (D1 convention bridge, finite-access, theorem retyping on Z, notation clashes, R^n claim narrowed, LRB caveats, metric scale).

</details>

---

## Historical Falcon content screen — affected by the Mamba continuation gap (2026-09-03)

Distance from claim: 1 (settling mechanism characterization).

Runner: `scratchpad/semantic_content_probe.py`. Results: `experiments/results/semantic_content_result.json`.

Ledger: `semantic_content_probe`.

**Method:** 8 suffix conditions on SVB-2 template (d3, Falcon-H1, 27 measurements each).

Tested: "# No changes.", "# TODO", "# Lorem ipsum dolor sit amet", "#", "# ", "pass", "\n", no suffix.

**Results:**

| Condition | Mean σ | Gain |
|---|---|---|
| # No changes. | 0.4299 | +53.5% |
| # (space) | 0.3295 | +17.7% |
| # TODO | 0.2963 | +5.8% |
| # (bare) | 0.2855 | +1.9% |
| baseline | 0.2801 | — |
| pass | 0.2410 | -13.9% |
| Lorem ipsum | 0.2351 | -16.1% |
| bare newline | 0.2230 | -20.4% |

**Current interpretation:** these contrasts are reproducible inside the defective multi-token cached runtime but are not faithful Falcon-state evidence. The registered strings must be rerun through the corrected interface before any content, semantic, or computation mechanism is promoted.

---

## Historical Falcon order screen — affected by the Mamba continuation gap (2026-09-03)

Distance from claim: 1 (structural prediction test).

Runners: `scratchpad/order_independence_probe.py` (v1), `scratchpad/order_independence_svb2.py` (v2).

Results: `experiments/results/order_independence_result.json` (v1), `experiments/results/order_independence_v2_result.json` (v2). Ledger: `order_independence_v1`, `order_independence_v2`.

**Method:** 7 suffix conditions (s0, s1_comment, s1_pass, s2_comment+pass, s2_pass+comment, s2_comment+comment, s2_pass+pass) at d3 on Falcon-H1. V1 used simplified template, V2 used SVB-2 template.

**V1:** Commutativity appeared to hold (diff 0.011) but comment was near ceiling (0.90).

**V2 historical observation:** comment→pass produces 0.084 higher σ than pass→comment, same sign in all 27 paired cases, inside the defective execution regime. No faithful-state commutativity or idempotence claim survives.

**Codex evidence gate (REVISE):** Order effect is real but projection/subspace mechanism language not earned. "Pass hurts" is heterogeneous across variables. Prompt-history sensitivity is an equally valid explanation. Licensed claim: behavioral order sensitivity on the fixed panel, not a latent projection or consolidation law.

---

## Historical SVB-2 on Falcon-H1 — affected by the Mamba continuation gap (2026-09-03)

Distance from claim: 2 (historical runtime diagnostic; not mechanism identification).

Runner: `experiments/run_svb_0.py experiments/config/svb_2.json`. Config: `experiments/config/svb_2.json`.

Results: `experiments/results/svb_2/`. Ledger: `svb_2_result`.

**Method:** Suffix counts [0,1,2,3,4,6,8] at depths 1-4. Neutral suffix = "# No changes.\n".

Fine-grained resolution to determine if d4 s1 peak is genuine.

**Results:** The observed maximum was at s1 for d2 and d4 and at s2 for d3;

the d3 s1/s2 difference was unresolved (p=0.86).

Recorded s1-relative gain increased across d2-d4 in the affected runtime:

d2 +29.6%, d3 +53.5%, d4 +87.9%.

The numerical profile is retained as historical diagnostic evidence only; it

does not confirm a faithful one-shot trigger.

---

## SVB-Qwen3-Formal — bounded suffix-conditioned response effect (2026-09-03; FIXED-PANEL WITNESS)

Distance from claim: 1 (bounded depth-dependent response intervention).

Runner: `experiments/run_svb_0.py experiments/config/svb_qwen3_formal.json`.

Results: `experiments/results/svb_qwen3_formal/`. Ledger: `svb_qwen3_formal`.

**Method:** Full SVB on Qwen3-1.7B-Base (pure transformer, no recurrence). 621 calls, 3.3 min CPU.

**Results:** On this Qwen fixed panel, the comment intervention increases mean

correct-digit probability by 0.0118, 0.0487, 0.1087, and 0.1263 at depths 1–4.

The paired change is positive in 24/27 cells at d1 and 27/27 at d2–d4. Among

tested suffix counts `{0,1,2,4}`, s1 has the highest mean at d2–d4.

**Corrected interpretation:** this is one prompt-family-bounded extra-text

response effect. The affected Falcon measurements cannot provide a clean

cross-architecture replication. Added computation, token position, lexical

content, syntax, and attention state change together. No universal settling

law, prior answer encoding, architecture mechanism, or efficiency claim is

licensed.

---

## Qwen suffix-response probes — descriptive mechanism screen (2026-09-03)

Distance from claim: 1 (bounded response characterization; mechanism unresolved).

Runners: various probe scripts in scratchpad. Results in STATE.md and NOTEBOOK.md.

Series of quick probes on Qwen3-1.7B-Base:

1. Double comment (+11.8%) is below single comment (+13.0%); this rejects a simple monotone token-count account, not all computation-time accounts.

2. Python `#` (+13.0%) exceeds C++ `//` (+2.9%) inside the Python prompt family; syntax, lexical familiarity, and position remain entangled.

3. Docstrings exceed comments (+17.5% at d3), while a competing value lowers the score by 26–34% on tested cells.

4. The best tested task-relevant reminder at d4 reaches σ=0.940, above raw d2 (0.897); because it supplies relevant content, it is not latent-only computation evidence.

---

## Historical SVB-1 Falcon depth curve — affected by the Mamba continuation gap (2026-09-03)

Distance from claim: 2 (archived measurement from a defective cached-state interface).

Runner: `experiments/run_svb_0.py experiments/config/svb_1.json`. Config: `experiments/config/svb_1.json`.

Results: `experiments/results/svb_1/`. Ledger: `svb_1_launch`, `svb_1_result`.

**Method:** Extends SVB-0 to depths 1-4, single-var only (two-var skipped — already known to fail). Same model, same task family, same suffix profile [0,1,2,4]. Runner parameterized with CLI config path and `single_var_only` flag. Pre-registered predictions: geometric decay r≈0.73, σ_d3≈0.36, σ_d4≈0.26.

**Depth capacity curve:**

| Depth | σ | CI | κ | CI |
|---|---|---|---|---|
| 1 | 0.681 | [0.637, 0.725] | 0.712 | [0.691, 0.733] |
| 2 | 0.497 | [0.437, 0.557] | 0.501 | [0.472, 0.531] |
| 3 | 0.280 | [0.213, 0.350] | 0.243 | [0.218, 0.267] |
| 4 | 0.229 | [0.182, 0.280] | 0.190 | [0.174, 0.206] |

Recorded decay ratios are d1→d2=0.73, d2→d3=0.56, d3→d4=0.82. They reject the preregistered geometric fit **inside the affected runtime only**.

**Recorded suffix profile across depths:**

| Depth | s0 | s1 | s2 | s4 | Peak | Gain |
|---|---|---|---|---|---|---|
| 1 | 0.681 | 0.669 | 0.560 | 0.396 | s0 | — |
| 2 | 0.497 | 0.645 | 0.597 | 0.516 | s1 | +30% |
| 3 | 0.280 | 0.430 | 0.441 | 0.338 | s2 | +57% |
| 4 | 0.229 | 0.431 | 0.401 | 0.298 | s1 | +88% |

**Historical interpretation, superseded:** the recorded curve is non-geometric and its largest tested suffix-conditioned gain rises from d2 to d4. Because the multi-token continuation discarded cached recurrent state, it cannot establish a phase transition, stored-but-inaccessible bindings, a recurrent settling mechanism, or a native cost law. It remains a diagnostic profile of that runtime.

**Evidence gate:** superseded by the 2026-09-03 Mamba continuation audit and the append-only correction `svb_decode_verification_audit_correction`.

---

## Historical SVB-0 on Falcon-H1-1.5B-Instruct (2026-09-03; AFFECTED BY MAMBA GAP)

Distance from claim: 2 (the task remains useful, but the recorded cached-state result is not faithful hybrid-state evidence).

Runner: `experiments/run_svb_0.py`. Config: `experiments/config/svb_0.json`.

Results: `experiments/results/svb_0/`. Ledger: `svb_0_launch`, `svb_0_result`.

Spec: `theory/closed/SVB_0.md`.

**Method:** Python lexical scoping as the task family: outer assignment → inner function call (shadows variable) → scope closure → query. Falcon-H1-1.5B-Instruct selected for code capability + recurrent state (DynamicCache save/restore for state injection). 11-bin response law: {digit 0-9, OTHER}. 3 variables (x,y,z), 9 outer values (1-9), depths 1-2, suffix counts [0,1,2,4] neutral comment lines.

Competence staircase: direct assignment → single-var depth-1 → two-var depth-1.
Single-var and two-var science observations with suffix profiles. 3 observables:
σ (scope binding fidelity = P(correct digit)), κ (path contrast = TV between
different outer values), ι (entity interaction = variable-specific vs global).
Null ladder: uniform, inner_value, mean_dist, identity. Bootstrap CIs (1000 resamples).

**Competence:** Rung 1 PASS (27/27 = 100.0%, gate 90%). Rung 2 PASS (27/27 = 100.0%,
gate 85%). Rung 3 FAIL (23/30 = 76.7%, gate 80%).

**Verdict: INSUFFICIENT_SCOPE_BINDING.** Two-var depth-1 competence (76.7%) below
80% gate. Formal adjudication stops at the competence check. However, all observables
computed from 1188 observations (1854 model calls, 4385s/73min CPU).

**Terminal correction:** all suffix/state observables below were captured through
the defective multi-token cached continuation. They remain historical runtime
measurements and cannot establish faithful state, binding, access, or mechanism.

**Observables:**

- σ_d1 = 0.6811 (CI: [0.637, 0.725]), σ_d2 = 0.4975 (CI: [0.437, 0.557])
- κ_d1 = 0.7123 (CI: [0.691, 0.733]), κ_d2 = 0.5009 (CI: [0.472, 0.531])
- ι = 0.3593 (CI: [0.343, 0.376])
- Depth-1 suffix profile: s0=0.681, s1=0.669, s2=0.560, s4=0.396
- Depth-2 suffix profile: s0=0.497, s1=0.645, s2=0.597, s4=0.516

**Null ladder:**

- d1: uniform=0.627, inner_value=0.833, mean_dist=0.597, identity=0.712
- d2: uniform=0.609, inner_value=0.636, mean_dist=0.555, identity=0.501

**Historical profile:** the affected path produced registered contrasts across
depth, entity, and suffix conditions. Its two-variable competence rung failed.
The later runtime audit supersedes the causal-control, variable-specific binding,
recurrent breathing-room, and “strongest positive signal” interpretations.

---

## PMO-0R — Path-Memory Observability Revised on Finch-3B (2026-09-02; TASK_POPULATION_VOID)

Distance from claim: 1 (bounded continuation-distinguishability witness).
Runner: `experiments/run_pmo_0r.py`. Config: `experiments/config/pmo_0r.json`.
Results: `experiments/results/pmo_0r/`. Ledger: `pmo_0r_launch`, `pmo_0r_result`.
Spec: `theory/closed/PMO_0R.md` (Codex R1+R2 locked).

**Method:** Corrects two PFC-0 defects (symmetric endpoints, 3-logit renormalization).
Asymmetric panels (entities end at different locations), 4-bin response law
{kitchen, garden, office, OTHER} — full next-token softmax, no renormalization.
9 roots × 3 panels × 6 extensions = 162 history states. 2 matched pairs per
configuration for commutation defect κ. Suffix injection via saved recurrent
states at 0/1/2/4 macro repetitions. Competence staircase: direct facts →
2-action → 4-action → suffixes. 9-method cross-fitted null ladder.

**Verdict: TASK_POPULATION_VOID.** Direct fact competence failed at rung 1
(0/36, 0.0% accuracy). Model puts ~65% probability on continuation tokens
("answer", "question") vs ~35% on all location tokens combined. Competence

gate requires correct location > P(OTHER) — unreachable with this template.
Even relaxed (argmax among 3 locations), accuracy only 55.6% due to kitchen bias.

**What was learned:**

(1) PFC-0's 3-logit renormalization was hiding model incompetence. After renormalization, kitchen at 68.5% looked like clear discrimination; the raw model allocates only 24% to kitchen (its strongest location) and 6%/5% to garden/office. Codex was correct to flag renormalization as a defect.
(2) Finch-3B's entity-location query interface is fundamentally limited for path-memory measurement. The model discriminates among locations but doesn't produce location-dominated responses with natural-language prompts.
(3) Kitchen calibration bias persists: kitchen is the default regardless of correct answer, causing 44% of relaxed errors.

**Closure:** This response interface (4-bin + explicit-choice template) on Finch-3B is closed as unusable. Competence failure does NOT close path memory as a concept, entity discrimination (TV=0.43), or bit-exact state replay.

**Codex evidence gate: DEFERRED (Codex credits exhausted until 2026-09-06).**

---

## PFC-0 — Path-Fiber Calculus v1 on Finch-3B (2026-09-02; TASK_POPULATION_VOID)

Distance from claim: 2 (Codex evidence gate correction — K is researcher-imposed 3×3 stochastic matrix on softmax simplex; composition is ordinary matrix multiplication; imported probability algebra, not native math).
Runner: `experiments/run_path_fiber_v1.py`. Config: `experiments/config/path_fiber_v1.json`.
Results: `experiments/results/path_fiber_v1/`. Ledger: `pfc_0_launch`, `pfc_0_result`.

**Method:** Four-corner path square (p00, pL, pR, pLR) with washout tail.
9 roots × 3 panels × 6 paths × 2 queries = 324 endpoint specs + 72 replay calls.
Cross-fitted stochastic transports K_L, K_R learned from 3 training corners, predict held-out pLR. SLSQP with ridge 1e-3. 3-fold cross-fitting on roots.
7 baselines: parser, last-1, last-2, multiset, discounted (LOO lambda), primitive composition (Adam 3000 steps, 6 channel types), causal 1-NN.

**Verdict: TASK_POPULATION_VOID.** Competence gate failed (washed 0.79, raw 0.72, need 0.95). PFC transport clean (coverage 1.0, coherence 0.002) but loses to all baselines except causal kNN. Parser best at TV 0.019 vs PFC at 0.038.
Defects below gate (0.03 < 0.05 required). Advantages all negative.

**What was learned (Codex evidence gate corrected):**

(1) Competence failure is garden-specific (all failing arms target garden; kitchen/office are 1.000) — answer-token calibration, not sequence-length capacity.
(2) "Washout erases signal" unsupported — raw-to-washed decrease only 0.006 TV (CI crosses zero); one panel increases. At most attenuation, not erasure.
(3) Individual K edges improve ~0.006 TV over identity (significant), but composed $K_L \cdot K_R$ is worse than identity by 0.008 TV (CI [−0.015, −0.002]). Composition destroys individual edge gains. Panel-additive residual (0.020) beats K (0.024).
(4) Stochastic-K vehicle closed. Next: PMO-0 (path-memory observability via common-suffix distinguishability, no washout, competence staircase).

---

## PSR-v2 — Corrected Predictive-State Adjudication on Finch-3B (2026-09-02; INVALID_PSR_V2 per Codex evidence gate)

Distance from claim: 0 (the refined quotient and transition law ARE native math).
Runner: `experiments/run_psr_v2.py`. Results: `experiments/results/psr_v2/`.
Ledger: `psr_v2_launch`, `psr_v2_complete`, `psr_v2_evidence_gate`.

**Method:** Attempted corrected adjudication addressing PSR-v1 evidence gate issues. Frozen train/test split (d0+d1=63, d2=54 eval). Argmax quantization (deviated from approved Q16). Construction-only transition table. Full null ladder: parser, kNN, last-action, shuffled. 702 model calls.

**Raw result:** 21 classes, 6 suffixes, right congruence reported 0 violations. Coverage: 19/54=35.2%. kNN TV=0.1090 vs quotient TV=0.1183 on 19 covered rows. Action descent: 0/0 (untestable). Within-class TV: 0.1542 (mean), 0.4998 (max).

**Codex evidence gate: INVALID_PSR_V2 — not a valid scientific negative.** Multiple deviations invalidate confirmatory adjudication: (1) horizon safety violation (d1 suffixes query d2 behavior); (2) argmax instead of approved Q16; (3) right congruence "0 violations" VACUOUS — all 9 d0 anchors singletons, no eligible pairs; (4) action descent 0/0 = untestable; (5) coverage 35% vs required 90%; (6) no actual recurrent-state substitution; (7) kNN comparison target-informed; (8) wrong statistical test.

**Licensed sentence (Codex, verbatim):** PSR-v2 is an invalid confirmatory adjudication, not a valid negative result: the implemented argmax quotient used out-of-horizon response laws, its zero-violation right-congruence diagnostic was vacuous because all depth-0 anchors were singleton classes, composition covered 19/54 histories, and action descent and causal substitution were not tested; RCQ is therefore closed on this task by the bounded-round protocol, not empirically falsified.

**What we learned:** (1) Horizon-custody law required. (2) Nonvacuity certificate essential: 0/0 = N/A. (3) Argmax cannot define predictive equivalence. (4) Fair evaluation needs common denominator and task-clustered inference. (5) Response similarity ≠ causal substitution. (6) Need multiple histories per operational state. RCQ closed on entity-location tracking by protocol, not falsified.

---

## PSR-v1 — Predictive-State Refinement on Finch-3B (2026-09-02; EVIDENCE-GATE NO-GO)

Distance from claim: 0 (the refined quotient and transition law ARE native math).
Runner: `experiments/run_psr.py`. Results: `experiments/results/psr_v1/`.
Ledger: `psr_v1_launch`, `psr_v1_complete`, `psr_v1_evidence_gate`.

**Method:** Nerode-style counterexample-guided refinement. Start with Γ = {2 direct queries}. Build behavioral quotient (greedy clustering, mean TV ≤ 0.10). Check right congruence: for each class, verify all members' post-action successors land in the same class. On violation, add action+query suffixes to Γ, recompute.

**Budget:** 3 rounds, 2000 calls max, 80 states max. Used 1638 calls.

| Round | Γ size | Classes | Violations | New suffixes |
|---|---|---|---|---|
| 1 | 2→12 | 50 | 9 | 10 |
| 2 | 12→14 | 41 | 9 | 0 (exhausted) |
| 3 | 14 | 41 | 9 | 0 |

**Raw result:**

- 41 classes from 117 histories (2.9:1 compression, 14 singletons)
- Selected-coverage composition: 12/19 (35 histories uncovered)
- Common-denominator: 12/54=22.2% vs parser 8/54=14.8% (p=0.229, NS)
- Right congruence: 9 violations remain

**Codex evidence gate (NO-GO on headline claim):**

1. ~~48.3pp surplus~~ WITHDRAWN — denominator mismatch (12/19 vs 8/54)
2. Not valid Nerode refinement — classes merged (50→48→41) due to greedy TV averaging with new low-distance suffixes diluting existing differences
3. Comparison unfair — quotient uses 14 suffixes + learned lookup vs parser using only ground-truth abstract state
4. Coverage selection bias — 19 testable cases are mechanically easy ones
5. Simpler controls not run (kNN, memorization, last-action, shuffled)
6. Proposed full-table fix trains on test answers — unsafe

**Licensed sentence:** "In a transductive selected-coverage screen, a thresholded response-signature partition correctly predicted 12 of 19 covered two-action class labels; no predictive surplus or quotient action law is established."

**What we learned:**

1. Path-conditioned response signatures contain reusable transition info
2. 41 distinguishable behavioral states exist (vs 9 abstract), but greedy order-dependent clustering ≠ genuine equivalence relation
3. The composition test must use identical denominators and proper train/test
4. Greedy exemplar clustering is non-transitive — need proper refinement
5. Positive exploratory evidence justifies ONE corrected adjudication

---

## RCQ-0 — Real Causal Quotient on Finch-3B (2026-09-02; IN PROGRESS)

Distance from claim: 0 (the quotient and action law ARE the native math).
Runner: `experiments/run_rcq0.py`. Config: `experiments/config/rcq0_v1.json`.
Spec: `theory/closed/REAL_CAUSAL_QUOTIENT.md`. Ledger: `rcq0_substrate_confirmed`, `rcq0_v1_composition_fail`.

**Substrate selection:**
Tested RWKV-4 (169M, 430M, 1.5B), RWKV-6 Finch (1.6B, 3B). Entity discrimination gate (asymmetric-state Q0-Q1 TV > 0.10) confirmed only on Finch-3B (TV=0.43). RWKV-4 at all sizes tracks location dominance, not entity-specific state (TV=0.03). Finch-1.6B marginal (TV=0.08). State replay bit-exact (TV=0.000000). Entity swap via state injection confirmed (TV=0.41/0.46).

**Task:** 2 entities × 3 locations = 9 joint states. 6 macro-actions. 2 probes.

Teacher-forced log-likelihood scoring.

**8 iterations, varying quotient construction:**

| Run | Method | Classes | Comp Top-1 | Trans Cons | Sub Same |
|---|---|---|---|---|---|
| 1 | δ=0.05 hard | 35/36 | 0/0 | n/a | n/a |
| 2 | δ=0.10 hard | ~35 | 0/0 | n/a | n/a |
| 3 | TV 0.10 + moved | 26 | 0.25 | ~0.85 | ~0.08 |
| 4 | TV 0.10 direct | 17 | 0.47 | ~0.88 | ~0.06 |
| 5 | TV 0.15 phrased | 15 | 0.34 | 0.88 | 0.07 |
| 6 | TV 0.05 word-order | 16 | 0.43 | 1.00* | 0.02 |
| 7 | GT 9-state (4 phr) | 9 | 0.51 | 0.86 | 0.13 |
| 8 | GT 9-state (1 phr) | 9 | 0.65 | 1.00* | n/a |

(*) Trivially 1.0 due to single member per class.

**Key finding: path dependence.** Within-state word-order TV: min=0.0004, max=0.2948, median=0.09. Post-action distributions differ from direct-statement distributions by TV~0.25. The model encodes HOW information was presented.

**What we learned:**

1. Entity discrimination emerges between 1.6B and 3B in RWKV-6
2. The model has genuine entity state (discrimination + injection + substitution)
3. The 9-state quotient has real structure but cannot compose (gate: 90%)
4. Path dependence prevents discrete quotient composition
5. No parser surplus: quotient TV=0.24 vs parser TV=0.19
6. Affine behavioral dynamics under investigation

---

## HANDLE-mu Rung 1 — Causal Handle Algebra, distance-1 (2026-09-01; PIPELINE-INVALID)

Distance from claim: 1 (designed latent world). 7x7 key-lock grid, 5 causal handles (2 keys, 2 locks, goal; agent excluded), partial visibility (Manhattan r=2), observation identity permuted per step. Five architectures: dense typed slots (6x32, all-pairs messaging, 20,927 params), learned-sparse slots (top-2, 20,927), flat GRU (19,930), historyless (10,207), direct-state oracle. Training: next-obs MSE + next-event CE, 40 epochs, 3 seeds (42, 137, 2026), 2048 train / 512 val / 1024 test trajectories. Seven pre-registered gates. Runner: `experiments/run_handle_mu.py`. Spec: `theory/closed/HANDLE_MU.md`. Ledger: `handle_mu_rung1`.

**Prediction metrics (event macro-F1 / status macro-F1):**

| Model | Seed 42 | Seed 137 | Seed 2026 |
|---|---|---|---|
| Oracle | 0.990 / - | 0.996 / - | 0.996 / - |
| Dense slots | 0.991 / 0.337 | 0.992 / 0.348 | 0.996 / 0.330 |
| Sparse slots | 0.988 / 0.330 | 0.991 / 0.345 | 0.994 / 0.335 |
| Flat GRU | 0.682 / 0.343 | 0.383 / 0.218 | 0.386 / 0.245 |
| Historyless | 0.655 / 0.299 | 0.814 / 0.297 | 0.915 / 0.297 |

**Gate results:**

| Gate | Seed 42 | Seed 137 | Seed 2026 |
|---|---|---|---|
| Eligibility | FAIL | FAIL | FAIL |

| | | | |
|---|---|---|---|
| Causal consumption | FAIL | FAIL | FAIL |
| Shielding | PASS | PASS | PASS |
| Timing | PASS | PASS | PASS |

**Overall verdict: PIPELINE-INVALID (Codex R3).** Not a scientific negative — five protocol bugs invalidate the run. Eligibility never passes (status F1 ~0.33, need >=0.90). Causal consumption improvement = 0 or negative across all seeds. Bounded spec/runner repair justified.

**What we learned:**

1. **MSE loss drowns status signal.** Status is 4/27 dims of the observation record, trained with MSE. Status changes are sparse events. Model predicts majority class (status_acc ~0.69, macro-F1 ~0.34). Needs separate CE head for status.
2. **Flat GRU bottleneck.** Parameter-matching forces flat GRU to hidden_dim=33 vs slots' effective 192-dim state. Flat GRU is WORSE than historyless in 2/3 seeds (0.38 vs 0.81-0.91). The "within 3 points" gate is structurally impossible.
3. **Events are too predictable.** Historyless achieves 0.91 event F1 (seed 2026) — events can be predicted from current observation alone. Undermines need for temporal causal tracking.
4. **Slot swap targets wrong slot 88% of the time.** Identity permuted independently per trajectory means donor slot N and recipient slot N usually carry different handles. Codex R3 diagnostic: same_numeric_slot = 11/93 pairs.
5. **Shared suffix not actually shared.** The paired history finder uses donor actions as suffix but recipient trajectory has different actions. zero full-suffix matches.
6. **Events identical at contact 94% of the time.** Only 5/88 contacted pairs have different events at the contact step. Most events are "none."
7. **Only keys (handles 0-1) have paired histories.** Locks and goal never independently differ between same-level trajectories.

---

## FBA-0 — Factored Bottleneck Architecture campaign (2026-09-01; FAIL)

Distance from claim: 1 (engineered-factorization control). Synthetic Z/8×Z/4 POMDP, 16 opaque actions, T=3 episodes, 85/15 confusion matrix. Six architectures: FBA (16/16, 33,664 params), flat GRU (40K), flat-matched (33K), asymmetric split (24/8, 34,688), modular (4×8, 34,688), flat bottleneck (37,760). Three seeds (42, 137, 2026). 2000 epochs, cosine LR (1e-3→1e-5), batch 256. Kill gates: K4 (all train≥0.90), K6 (FBA>best flat≥20pp), K7a (FBA>asym≥15pp), K7b (branch interchange>historyless null with Bonferroni CI), paired effects. Response-class equivalence split: 21/3/8 (train/val/test) from 32 classes. Oracle ceilings: historyless ~72-73%, recurrent ~95-96%.

Runner: `experiments/run_fba_0.py`. Theory: `theory/closed/FBA_BRIDGE.md`. Ledger: `fba0_full_campaign`.

**Test accuracies:**

| Model | Seed 42 | Seed 137 | Seed 2026 |
|---|---|---|---|
| FBA (16/16) | 0.847 | **0.915** | 0.897 |
| Flat GRU (40K) | 0.802 | 0.832 | 0.847 |
| Flat matched (33K) | 0.796 | 0.804 | 0.775 |
| Asym split (24/8) | **0.924** | 0.828 | 0.924 |
| Modular (4×8) | 0.891 | 0.805 | 0.847 |
| Flat BN (37K) | 0.884 | 0.812 | **0.926** |

**K7b branch interchange (cross-accuracy, null=0.722):**

| Seed | Cross | CI | Orient | Verdict |
|---|---|---|---|---|
| 42 | 0.630 | [0.571, 0.687] | A=place,B=fiber | FAIL |
| 137 | 0.884 | [0.846, 0.923] | A=fiber,B=place | PASS |
| 2026 | 0.414 | [0.355, 0.481] | A=fiber,B=place | FAIL |

**Overall verdict: FAIL.** Joint predicate 0/3 seeds. K7b passes for seed 137 only.

**What we learned:**

1. Architecture matters: structured > flat consistently, but WHICH structure wins is seed-dependent.

2. The 16/16 symmetric split is not robustly optimal — asymmetric 24/8 wins 2/3 seeds on test accuracy.

3. Branch interchange is possible (seed 137: cross=0.884) but does not emerge consistently across seeds. The response-class split (which classes land in train vs test) determines whether factored representations develop.

4. Pre-registered kill gates (20pp, 15pp gaps) were too aggressive — actual effects are 4-9pp.

5. Wrong-channel controls (same-factor preservation) consistently pass (0.93-0.98 range) — the branches carry factor-relevant information even when cross-episode hybrids fail.

6. Flat bottleneck (37K) can match or beat FBA (seed 2026: 0.926 vs 0.897), suggesting bottleneck constraint alone, without independent branch updates, is sometimes sufficient.

**Transferable residue:** Width allocation (how many dims per branch) matters more than product factorization. Alignment between architectural priors and task structure determines whether factored representations emerge. This informs next-direction choices about typed vs untyped architectural constraints.

---

## OCI/RAC — Real-entity activation steering (2026-09-01; CLOSED per Codex round 10)

Qwen3-0.6B-Base, frozen, CPU-only. Real capital-city entities (Tokyo/Japan, Berlin/Germany, London/UK, etc.). Hidden-state transplant and function-vector composition at B20. Distance-from-claim: 1 (activation steering is R^n scaffolding, not native math; signals inform the next constructive program).

- **OCI-001 through OCI-003** — Operational positional-carrier confirmation. Cross-template routing follows ordinal clause position (96.5%), not token position. Sentence-position routing at B20 confirmed across 3 disjoint panels, 192+ transplant rows.

- **RAC-0 — POSITIVE (bounded)** (`results/rac_0/verdict.json`; `run_rac_0.py`). First successful composition in 75+ experiments. Two orthogonal function vectors (routing=position rv, relation=capital/language rlv; cos=-0.046) independently and jointly control retrieval. Composition generalizes 100% to held-out entity pairs. Survives 5 layers of separated computation (B15-B20). Layer-phase deformation: works B15-B21, FAILS at B22 (content commitment transition).

- **RAC-1 — FAIL (Codex round 9; algebra program CLOSED)** (`results/rac_1/verdict_affine.json`; `run_rac_1.py`). Affine coordinate-overwrite setters: S_v(h) = h + direction * (tau - c_dim(h)). True mathematical idempotence (48/48). correct_top1 composition 21/36 (58%) — binding metric per spec. Metric substitution error caught by Codex: comp metric (32/36, 89%) was p_target>p_start, not top-1. Same-layer commutativity tautological (affine construction, rv perp rlv). Transport: ALL DEFORM. Codex ruling: "useful local coordinate actuator, not a response quotient carrying a product algebra."

- **Codex direction round 10 — END FROZEN-RESIDUAL MEASUREMENT LANE.** Jacobian rank experiment REJECTED (already run as CPD-001, R^n trap; full rank 40/40, effective rank 6-28). Terminal diagnostic prescribed: Gate I (logit-additive null) + Gate F (response-fiber stability). Outcome table governs closure characterization.

- **Terminal diagnostic — CLOSE AS DECODER/LOGIT COMPETITION** (`results/terminal_diagnostic/verdict.json`). Gate I: logit-additive null l_a+l_b-l_0 explains 99.1% of composition effect (sqrt(JSD) = 0.0001 between predicted and actual composed distributions; 12/12 top-1 match). The "composition" in RAC-0/RAC-1 is ordinary logit addition through a linear unembedding — decoder competition, not nonlinear response geometry. Gate F: NO_INTERFACE — no template pair has baseline sqrt(JSD) < 0.15 (smallest gap: 0.19). The model's response law is presentation-dependent; no template-invariant response fiber exists. Per Codex outcome table: CLOSE AS DECODER/LOGIT COMPETITION. Frozen-residual measurement lane ends.

- **Codex direction round 11 — DIRECTION DIALOGUE (round 1/3).** Codex recommends stopping the frozen-model discovery program (agreed). Provides "genuinely different" criteria table: agent state (not residual vector), native actions (not external edits), behavioral identity (not cosine/PCA), persistent environments (not prompt templates), composition surviving time and relabeling. D1-D9 should be design contracts. Bar: "not induced by or dependent upon chosen vector coordinates." Three options: (a) archive, (b) falsification-methods paper, (c) new stateful-substrate design project. Codex leans toward (b) then (c). Pushback: option (c) IS the FBA constructive program per AGENTS.md second lens.

 **Codex direction round 12 — CONDITIONAL YES (round 2/3).** FBA IS option 3. Four additions required: (1) partial observability/recurrence, (2) response-law definitions for place/fiber, (3) four-way comparison (flat, FBA, scrambled FBA, modular), (4) strengthened K7 ablation. Tautology risk: architecture and world share factorization. Falsifier genuine. Correct claim: "behaviorally grounded structural prior enables compositional generalization." One more spec-hardening round before compute.

 **Codex direction round 13 — SPEC HARDENING (round 3/3, in progress).** All four additions addressed. Architecture updated with independent encoding, four baselines designed, partial observability via noisy observations, K7 strengthened. GO/NO-GO decision pending.

---

## Phase 3 — Co-designed dynamical carrier (2026-09-01 →)

Build a learned carrier whose internal states compose under causal transplantation. Distance-from-claim: 0 (the carrier IS the artifact).

 **endogenous_action_carrier_v1 — STOPPED (registered PASS, Codex ruling: architecturally tautological)** (`results/endogenous_action_carrier_v1/evidence.json`, `verdict.json`; Codex ruling: `scratchpad/codex_eac1_next_rung.txt`). 150K CPU forwards, 62 seconds, 359K params. Structured world encoding (key-value transition triples) + differentiable attention lookup + context-dependent readout. All 7 registered gates PASS across 3 seeds: acc 99.4-99.8%, self-patch 0.0, same-place 100%, descent 95.6-100%, three-way 100%. **Codex review determined result is tautological:** carrier IS the next-state embedding; host/donor share the same world; no donor action representation is produced or transplanted; a symbolic table lookup achieves identical results. The causal gates validate the differentiable associative-memory construction, not a compositional action carrier or native mathematics. **EAC/LAC line STOPPED.** A non-tautological continuation would require hard access control, no raw successor embeddings, independent relabelings, held-out compositions, and matched controls — a new preregistration.

 **learned_action_carrier_v0 — PORTABLE_NOT_COMPOSABLE (terminal)** (`results/lac0_run_20260901_064645/`; Codex design gate: `scratchpad/codex_init_gate_response.txt`). 739K-param typed neural machine: WorldWriter→M, ActionWriter→A, Composer(GRU)→μ(a1,a2), gated 2-block Executor(M,A)→M', Renderer(M',legend)→logits. 730K-param untyped transformer control. 5000 steps × batch 128 × 3 seeds, CPU only. **Claim-bearing run (Xavier init):** seed 42: prim=100%, held_comp=33.83%, portability F=1.0, sequential=33.8% FAIL; seed 137: prim=100%, held_comp=14.82%, sequential=11.6% FAIL. Untyped: 12.5-13.4% (chance). **Cross-eval of provisional checkpoint (default init, Codex):** held_comp=96.11% BUT sequential_agreement=0.8% FAIL (gate ≥90%). **Critical finding: circuit selection.** Default init learns endpoint composition but NOT sequential execution (E(E(M,a1),a2) = 0%). Xavier learns sequential execution (94.8%) but NOT composed carrier (34%). These are different optimization basins. Neither passes complete Gate 4. Stop condition §14.7(b): portability without composition is terminal. **Residue:** typed architecture → perfect primitives + portability; untyped cannot; endpoint vs sequential composition are distinct targets; GRU shortcuts ≠ algebraic composition; successor must define composition via response-law quotients.

---

## Phase 5 — PSQ-1: Predictive-State Quotient (2026-09-01, killed at eligibility)

Test whether frozen Qwen3-1.7B-Base can track state in a 64-state two-dial world (Z8×Z8) via Python-completion prompts. Distance-from-claim: 0 (predictive-state quotient geometry IS native math). Codex R1-R3 direction dialogue.

 **psq1_v1_capability — NO_INTERFACE** (`results/psq1_v1/capability_screen.json`). 128 CPU forwards, 217s. 4-shot Python-completion, 2-8 operations per test, separate x/y queries. Overall 53.91% (gate ≥95%). Per-cell: x_0=50.0%, x_1=59.4%, y_0=9.4%, y_1=96.9%. Model almost always predicts "0" for y queries; at chance for x. No state tracking. Stop condition: NO_INTERFACE. No repair per Codex R3. **Note:** the predeclared fallback (Qwen3-8B-Base) was already tested in the earlier PSQ-1 round (see Phase 5 PSQ-1 ALL SUBSTRATES section below) and also failed (55.5%, NO_INTERFACE). Qwen3-4B-Base smoke test (56.2%, 16 items, this session, informal) further confirms: all sizes 0.6B–8B fail.

---

## Phase 4 attempt — KV command-slot transplant (2026-09-01, killed at eligibility)

Test whether frozen Qwen3-0.6B-Base admits modular KV-level command execution. Distance-from-claim: 1 (modular execution is prerequisite for native algebra). Codex direction R1+R2: engineering falsification, not native math.

 **permutation_eligibility_v1 — INELIGIBLE (kills 4-launch program)** (`results/permutation_eligibility_v1/eligibility.json`, `cases.json`). 200 CPU forwards, 318s. Three-item permutation (rotate left/right/reverse) with fixed 3-shot prompt, 8-symbol pool. Overall accuracy 48.0% (gate >=95%), termination 0.5% (gate >=95%). Per-op: rotate left 13.4%, rotate right 34.3%, reverse 97.0%. Model can reverse but cannot track cyclic rotation. Kill condition fires. No Launch 2-4. Direction dead.

---

## Phase 2 — Non-R^n behavioral algebra (2026-08-31 →)

Instrument: logit lens (apply model's final layernorm + unembedding at each layer) + sqrt(JSD) as behavioral distance. Model: Qwen3-0.6B (28 layers, 1024 hidden dim), CPU-only. Synthetic fact-worlds (2- or 3-entity, controlled assignments).

 **query_port_composition_v1 — INCONCLUSIVE_ALLOCATION_STOP** (`results/query_port_composition_v1/evidence.json`, `verdict.json`). 144 CPU forwards (36 cells × 4 arms: clean + self-patch + L21 donor + L25 donor). Theory Section 12. Three families (ZOG/MIP, PLIM/KROT, DREN/VORN), 3 values each (three-way clash: s=v_r, t=v_{r+1}, d=v_{r+2} all distinct). Exact query-position hidden-state row-copy from donor to host at L21/L25. Instrument PASS: carrier ok, self-patch max=0.0, clean 94.4% (cluster LB=0.86), L21 viability 94.4%. **Composition gates all FAIL:** F(21)=0.306 [0.139] (at 3-way chance), C(21)=-0.062 [-0.201, 0.077], W(21)=0.125 [-0.024, 0.273]. Donor wins 58% at L21 (D21=0.583), source only 11%. L25: C(25)=-0.701 (pure donor-verbalizer copy). Localization L=0.639 [0.548] PASS — L21 is NOT the late verbalizer, yet still fails to compose. No named nonpass verdict reached (not enough for DONOR_VERBALIZER_COPY, not enough for HOST_INERTIA). The transplanted query state disrupts the host but does not direct toward the target answer — it scatters across the triplet with partial donor lean. **Terminal per Codex allocation ruling. Ends the Qwen prompt micro-world.**

 **observational_selectivity_quotient_v1 — OBSERVATIONAL_SELECTIVITY_VERBALIZER_SUFFICIENT** (`results/observational_selectivity_quotient_v1/evidence.json`, `verdict.json`). 48 CPU forward passes, 28-layer logit-lens profile, 12 undirected edges, 10,000 bootstrap resamples. Theory Section 11 (Codex design gate). Purely observational --- no bypass, no intervention. Measures layer-resolved selectivity contrast S(l) = E[d_rel(l) - d_irr(l)] using sqrt(JSD/ln2) at all 28 post-block layers. All 11 core gates PASS: integrity (d=0.00023), material (12/12), early null (B=0.008), window emergence (Gw=0.239 [0.137]), anchor G(25)=0.633 [0.554], R(25)=0.785 [0.712], OSQ(25)=0.706 [0.612], peak=L25, onset=L24, persistence S(27)=0.240 [0.184], presentation (std=0.644 [0.506]/rev=0.638 [0.512]), family (ZOG_MIP=0.664, PLIM_KROT=0.696, HESK_VORN=0.563). **Verbalizer null NOT rejected (V=1.01):** coarse-graining to 3-bin (v0, v1, rest) accounts for 100% of the selectivity signal (S^pi(25)=0.647 vs S(25)=0.641). The selectivity is entirely ordinary answer-token routing. R^n trap: escapes (no cosine/PCA/Euclidean in estimand). Claim ceiling: observational logit-lens measurements exhausted. Terminal.

 **endogenous_response_quotient_v1 — INVALID_OR_NO_PROPAGATION_CONTROL** (`results/endogenous_response_quotient_v1/evidence.json`, `verdict.json`). 144 CPU forward passes (48 cells x 3 arms). Theory Section 10. Compares block 25's native computation with identity bypass (skip block, pass pre-block state unchanged). No donor transplant --- purely endogenous. Three families, 4 worlds, 2 queries, 2 declaration orders. Instrument PASS (noop d=0.0). Material PASS (12/12). **Bypass viability FAIL (7/48)** --- identity bypass too destructive; off-manifold lesion. No scientific verdict. Descriptive: O-endpoint shows query-selective block-25 action (A_O=0.254 [0.198], C_O=0.174 [0.086], Sigma_O=0.428 [0.304]). F-endpoint amplification survives (A_F=0.159 [0.111]), compression does not (C_F=0.013 [-0.017]). Stability clean (ub=0.038). Terminal.

 **commitment_hysteresis_v1 — INCONCLUSIVE_ALLOCATION_STOP (Codex evidence gate: REVISE, corrections adopted)** (`4593ab0`; `results/commitment_hysteresis_v1/evidence.json`, `verdict.json`). 456 CPU forward passes (24 clean + 48x9 intervention). Tests whether prefix transplant at L21 leaves a causal trace that survives restoring the original host prefix after the commitment bottleneck (L25). Three families (ZOG/MIP, PLIM/KROT, HESK/VORN), 4 worlds each, 48 directed edges, 12 clusters. Controls perfect: self-patch 0.00, C25 (full restore) 0.00, all 12 clusters eligible. Corrected metrics (Codex independent reduction): **M=0.438 [0.383, 0.504] PASS**, **T=0.200 [0.144, 0.247] FAIL**, **H=0.403 [0.322, 0.512] PASS**, **U=0.092 [-0.005, 0.169] FAIL**, **L=0.162 [0.091, 0.222] FAIL**. Original reducer averaged all queries instead of using changed-entity query for T/U/L per Section 9. Under this exact whole-prefix intervention, an L21 transplant produced a response-law shift that remained after the clean host prefix was restored at L25. The corrected preregistered reduction cleared the descriptive M and H thresholds but did not clear the donor-directed T/U or localization L lower-bound gates. It does not establish absence of donor-directed transfer, generic disruption, or commitment-specific hysteresis. High H is compatible with ordinary causal propagation from replacing an entire upstream prefix. Terminal — do not mine high-T edges or advance to held-out names.

 **signature_restatement Phase 4d terminal anti-echo factorial — NO_INTERFACE, allocation stop (Codex evidence gate UPHOLD)** (`experiments/run_signature_restatement_v1.py --phase4d-only`; `results/signature_restatement_v1/phase4d_results.json`). 2304 forward passes (2208 factorial + 96 base-signature). Integrity passed. **Gate 1 (interface) FAIL:** confirming records followed on 47/48 and 44/48 coordinates; contradicting records on only 21/48 and 8/48. **Commitment-congruence asymmetry** (bounded discovery): append is nearly identity-like when congruent, unreliable overwrite otherwise. **Gates 2-4 unreached** with descriptive results: crossed-order recency rule did not pass (recency generally not excluded); alias logit shifts 3.62/2.39 nats establish keyed alias-content sensitivity below reliable argmax control. Terminal: prompt-renderer tuning ends; S^G receives no semantic upgrade. Anti-echo question remains inconclusive.

 **signature_restatement_v1** (`b70aac2`; `results/signature_restatement_v1/results.json`). Tests O1: does representative-independent restatement S^G_g from observable greedy signatures exist? **O1 RESOLVED: YES.** Idempotence: 100% greedy (96/96), JSD 0.077/0.071. Descent: 12/12 (100%) / 15/15 (100%) — fixes S^W's one failure. Place preservation 100%. **Fixed cyclic shuffle 0/32 (pairing-sensitive; textual echo unresolved).** Non-naturality persists with S^G: JSD 0.193/0.188. **NEW FINDING:** Correction does NOT descend to G (58%/80%). Typed square is pointwise K(Cx) vs C(Kx), not quotient-level.

Pattern: order-dependent — `_rev` representatives often ignore correction while `_std` accepts it. Correction effectiveness is itself presentation-path dependent. **Anti-echo alias control (Phase 4c, Codex REVISE): no anti-echo evidence.** Faithful alias did not exceed comparators by predeclared 30pp margin. Direct R(g) recovered 47.9%, ruling out deterministic latest-explicit-assignment. Implementation defects in shuffled arm. Literal signature renderer preserved 32/32 greedy signatures — do not call semantic or latent-space invariance.

 **predictive_fiber_action_v2** (`dc7d4ae`; `results/predictive_fiber_action_v2/results.json`). Codex v6 corrected experiment. Fixes v1 construction error: typed square S_{p'}.C vs C.S_p with both paths ending at corrected world. Full greedy signatures. Descent tested. **CONFIRMS COUPLING**: idempotence 100% greedy (JSD 0.070); typed square JSD 0.208 (registered 89.6% greedy, held-out 70.8% greedy). Held-out commutativity WORSE than v1's invalid test. Coupling is genuine. Descent: empty 100%, restatement 92-100%.

 **predictive_fiber_action_v1** (`e4e8ba7`; `results/predictive_fiber_action_v1/results.json`). *(Superseded by v2.)* Construction error: old-world restatement on both paths. Idempotence valid; square test invalid. Codex v6 review identified the error.

 **predictive_fiber_v1** (`4978a85`; `results/predictive_fiber_v1/results.json`). Codex-directed (v4). Tests whether distributional residual inside greedy fibers is predictive or presentation. Three pair classes, six continuations. **MIXED**: history>benign at baseline+corrections (3/3), history<benign after restatement (0/3). Cross-world smallest. Residual = predictive commitment + resetable presentation. Canonical restatement = synchronization.

 **rebroadening_test_v1** (`915988c`; `results/rebroadening_test_v1/results.json`). Re-broadened distribution is **MEANINGFUL**: 5-7/10 divergent tokens are history-related entity values. Model leaks entire fact-world into output. Repetition narrows 2-3x.

 **entropy_structure_v1** (`cc83d06`; `results/entropy_structure_v1/results.json`). **COMMITMENT BOTTLENECK**: entropy 0.05-0.30 bits at L24-25 (top-1: 0.999), re-broadens to 5.5-7.7. Explains greedy congruence (97%) + distributional failure (0%).

 **distributional_congruence_v1** (`048bae1`; `results/distributional_congruence_v1/results.json`). Full-distribution congruence (sqrt(JSD), threshold 0.05). **0/96 congruent**. JSD 0.07-0.45.

 **position_contribution_v1**, **three_fact_resolution_v1**, **mlp_decomposition_v1**, **attention_control_v1**, **continuation_congruence_v1**, **logit_lens_resolution_v1** — see STATE.md for details. Key findings: resolution (L21-25, up to 62x selectivity), not attention routing (r<0.25), whole-sequence value-space operation, generalizes to 3 facts, 97% greedy congruence.

 **fusion_fission_v1-v2b** — compositional structure series. Cosine blind; behavioral transplant sees structure; whole-state property; K-matrix instrument has defects (Codex v2b review).

 **causal_resolution_v1** — UNINFORMATIVE (full-state injection trivial).

 **predictive_setter_algebra_v1** — FAIL (16 types, primacy bias).

---

## Phase 1 record (2026-08-27 → 2026-08-31; PROGRAM REOPENED 2026-08-31; Phase 1 experiments below are closed results; Phase 2 begins with non-R^n approaches; audits #27–#50 adopted; orientation document `docs/HANDOFFS.md` is historical)

 **Theory (restart 2026-08-30; PROGRAM REOPENED 2026-08-31).** Adopted foundation: `theory/AXIOMS.md` D1–D9, Theorems 1/4/7/8, Propositions 2/6, native bridge definition (mathematics audits #42 and #44; D7 audit #48 REVISE adopted; licensed wording in `STATE.md`). Phase 1 Codex review verdict was STOP, but closure was not authorized by the project owner; native math existence is axiomatic (see `feedback_native_math_is_axiom.md` in memory). Five transferable insights deposited; Phase 2 begins with genuinely non-R^n approaches. The bullets below are retained as Phase 1's closed record; their "program remains paused / on restart" language is historical.

 **`register_bridge_preflight_v1` — PREFLIGHT PASS — EXPLICIT-LEGEND STATE LINEARLY DECODABLE (audit #39: UPHOLD; noncausal feasibility result, not a code-level or causal bridge)** (locked `8beb8e9`; result `d2acfe8`; ledger `register_bridge_preflight_v1_lock`, `register_bridge_preflight_v1_result`, `register_bridge_preflight_v1_audit39`; config `experiments/config/register_bridge_preflight_v1.json`; runner `experiments/run_register_bridge_preflight.py`; results `experiments/results/register_bridge_preflight_v1/`). `register_bridge_preflight_v1` — PREFLIGHT PASS: EXPLICIT-LEGEND STATE LINEARLY DECODABLE. In frozen Qwen3-1.7B-Base, cross-fitted rank-≤8 Ridge decoders evaluated on held-out entities × templates × a disjoint balanced permutation bank achieved 0.815 accuracy (entity-bootstrap LB 0.779; folds 0.828/0.852/0.766; minimum state recall 0.615), versus input-embedding 0.125, categorical 0.135, paired reassigned-legend original-state 0.016, and shuffle-null p99 0.204; the intact decoders followed the paired legend’s newly denoted state at 0.852, ruling out fixed tag identity. This is a noncausal explicit-legend lookup signal, not a code-level or causal bridge. The program remains paused; on restart, conduct

the required direction dialogue and then one held-out causal residual-to-writer-centroid injection test, with no synthetic staircase advance or further decoder sweep first. Entry below.

 **NLM-007 — CLOSED** under the program's terminal allocation rule, not by a scientific null (audit #22 closing statement, verbatim in `STATE.md`; ledger `nlm007_closed_audit22`). Terminal ladder: 34a raw CONTINUE -> 34a static CONTINUE -> 34b INCONCLUSIVE (terminal rung) -> 34c not run. No operational state, native law, composition, representation-level hostile hole, or independent replication was identified. Every bullet under the NLM-007 heading below is the closed record; its queue/order language is historical.

 **Toy quotient-world program (Rounds 36–37) — ENDED 2026-08-29** under the governance amendment in `AGENTS.md` (exact certificates are diagnostics only; one audit per result, which must answer "should this continue"; real models only; ratio tripwire). Rounds 36 v1 / 36b / 36c / 36d and Round 37 are closed results with one licensed reading each (audits #23–#26 and the Round 37 audit; verbatim in `STATE.md` "Closed toy program — licensed wording"). No learned artifact passed the complete exact reducer (only the oracle fixture); Round 37: `NO ARCHITECTURAL WIN`. Runners and configs were retired from the active path (`f6dac0e`; git history); verdicts retained under `experiments/results/operational_quotient_*/` and `experiments/results/presentation_quotient_v1_*/`. Entries below.

 **Real-model line (2026-08-29) — frozen-residual-stream constructions STOPPED as an allocation pivot (audit #28), not a scientific conclusion.** `coordinate_v1` UNINTERPRETABLE — INVALID POLARITY BASELINE; `coordinate_v2` KILLED at its baseline gate; `coordinate_v3` mechanics reproduced but audited (#27) into a narrow late lexical-control effect; `interchange_v1` closed by its locked raw-sign baseline, no swap arm ran. Verbatim replacement wording (audit #28): "Under the current apparatus budget, this sequence of frozen residual-stream constructions is not yielding a native-mathematics artifact, so open-ended layer, task, and decision-rule repair stops here. This is an allocation pivot, not evidence that frozen pretrained residual streams lack usable native structure." Entries below.

 **`state_bus_v1r1` — REGISTERED FAIL, CLOSED (audit #29; ledger `state_bus_v1r1_result`, `state_bus_v1r1_audit_stage`, `state_bus_v1r1_audit29`); no bus v2.** Licensed sentence (verbatim): **`state_bus_v1r1` is a fixed-construction FAIL: a 98,400-parameter supervised interface repeatedly injected a 16-dimensional code into frozen Qwen3-1.7B-Base, and across three seeds held-out same-state donors preserved every four-way categorical choice but failed the training-derived confidence-signature tolerance on 15–16/16 rows, while fixed-cycle cross codes changed taxonomy choice on 7/16 rows—always cat→dog in 3/4 and cow→horse in 4/4—and the complete registered gate vector also failed heldout taxonomy and the cross-consequence third/first movement criterion; taxonomy verbalizers were absent from the bus loss, but the all-pair sensitivity was donor-verbalizer-specific rather than state-general, so the licensed residue is a repeatedly maintained supervised response controller with pair-specific lexical/semantic steering, not autonomous persistence, abstraction, general interchangeability, or native latent mathematics.**

 **`interchange_v2` — REGISTERED CONSTRUCTION-LEVEL FAIL, CLOSED** (audit #30 adopted verbatim `fe3c541`; ledger `interchange_v2_lock`, `interchange_v2_result`); no v3. Licensed sentence and never-say list verbatim in `STATE.md` "Current statement".

 **`control_cost_v1` — REGISTERED CONSTRUCTION-LEVEL FAIL, CLOSED** (audit

#31 adopted verbatim `17b3d90`; ledger `control_cost_v1_result`, `control_cost_v1_audit31_correction`). Cost-law, rank, ratio and asymmetry readings withdrawn as censoring artefacts. Entry below.

- **Frozen-residual line STOPPED (Codex direction round 10, ledger `direction_r10_program_ruling`)** — an allocation stop point, not a proof that pretrained models lack latent mathematics.
- **`onewrite_state_v1` — KILLED PRE-LOCK** (ledger `onewrite_state_v1_killed_prelock`): the base model cannot apply a stated rule to visible tags; no state hypothesis was tested. Entry below.
- **`onewrite_recall_v1` — REGISTERED CONSTRUCTION-LEVEL FAIL, CLOSED** (unanimous, seeds 11/23/37; audit #32 adopted verbatim `3a47fd8`; ledger `onewrite_recall_v1_lock`, `onewrite_recall_v1_seed11`, `direction_r18_ruling`, `onewrite_recall_v1_result`, `onewrite_recall_v1_audit32`). Entry below.
- **`necessity_navigator_v1` — BUILT; audit-#32 blockers FIXED; post-fix smoke only; DEFERRED, not cancelled** (round 19; ledger `navigator_smoke_r32fixes`, `direction_r19_ruling`). Entries below.
- **`onewrite_recall_rung1` — staircase RUNG 1 — REGISTERED CONSTRUCTION-LEVEL FAIL, CLOSED** (unanimous, seeds 11/23/37; audit #33 adopted verbatim `25f65ac`; ledger `onewrite_recall_rung1_lock`, `onewrite_recall_rung1_result`, `onewrite_recall_rung1_audit33`, `onewrite_recall_rung1_rung0_diag`, `onewrite_recall_rung1_z_localization`). The one-write E/J interface stops under its predeclared rule. Entry below.
- **`oracle_actuator_rung0` — staircase RUNG 0 — REGISTERED FAIL (`FAIL — ORACLE ACTUATOR/SITE/RETRIEVAL CONSTRUCTION`), unanimous; audit #34 ADOPTED (licensed sentence and never-say verbatim in `STATE.md`)** (Codex round 20 design; ledger `direction_r20_rung0_design`, `oracle_actuator_rung0_preflight`, `oracle_actuator_rung0_lock`, `oracle_actuator_rung0_seed11`, `oracle_actuator_rung0_result`, `oracle_actuator_rung0_diag`). Nothing beyond the ledger row is licensed. Entry below.
- **Direction rounds 19–20** (ledger `direction_r19_ruling`, `direction_r20_rung0_design`): round 19 = navigator comparator rule (self = ceiling), navigator deferred, rung 1 built and locked; round 20 = oracle-code actuator rung 0 designed as the one next locked artifact, rung 0b (encoder on tag-token positions) only after a bounded rung-0 pass. NEXT: audit #34 -> Codex round 21.
- **`necessary_register_rung1` — QUALIFIED PASS — ANSWER-SUPERVISED EIGHT-SYMBOL WRITER INTO A FROZEN SYNTHETIC CONSUMER, seeds 11/23/37 (audit #38 adopted `d4b82b7`; wording in `STATE.md`)** (locked `ea2e831`; ledger `necessary_register_rung1_lock`, `necessary_register_rung1_result`; config `experiments/config/necessary_register_rung1.json`; results `experiments/results/necessary_register_rung1/run_result.json`). Own 0.966/1.0/1.0; counterfactual 0.964/1.0/1.0; shuffled-donor 0.967/1.0/1.0; telemetry cosine 0.72/0.42/0.49. Entry below.
- **`necessary_register_v1` rung 0 — QUALIFIED INSTRUMENT PASS —**

PERMUTATION-GENERALIZING ORACLE-CODE LABEL SELECTOR** (audit #37 adopted verbatim `abee584`; result `ff6c42b`; lock `be28305`; results `experiments/results/necessary_register_v1/run_result.json`). Own-code first-label accuracy 0.955/1.000/1.000; counterfactual following 0.962/1.000/1.000; not compositional. Licensed sentence and never-say list verbatim in `STATE.md` "Current statement". Entry below.

- **Audits #34–#36 adopted** (`oracle_actuator_rung0` FAIL wording; `site_oracle_v1` REGISTERED CONSTRUCTION-LEVEL FAIL, exact recipe closed as an allocation stop; `reachability_v1` MEASUREMENT, `NO SLOT-SPECIFIC GEOMETRY CONCLUSION`); the frozen-model line is closed; write-up `docs/STRUCTURED_NEGATIVE_2026_08_29.md`; licensed sentences and never-say lists verbatim in `STATE.md`.

## PSQ-3α — terminal experiment: task-trained Qwen3-1.7B-Base intervention (2026-08-31; CLOSED NO_INTERFACE)

Per Codex direction round 6 (CONTINUE ONCE, TERMINAL, ARTIFACT-FIRST): trained one seed of Qwen3-1.7B-Base on the Z_8×Z_8 two-dial world (5,000 steps, LoRA r=16, training loss 0.0154), then ran the micro intervention staircase (x-channel panel, 256 calls).

- **Result:** 69.14% accuracy (177/256), gate >=95%. **NO_INTERFACE.** Stopped at stage 1 per predeclared stop rule.
- **Progression:** frozen 0.6B 26.56% (PSQ-3μ) -> trained 1.7B 69.14% (PSQ-3α). Training substantially improves behavioral accuracy but the registered interface gate is not met.
- **Disposition:** per direction round 6, any outcome other than PASS closes the program as currently constituted.
- Runner: `experiments/run_psq3.py`. Config: `experiments/config/psq3_alpha.json`. Result: `experiments/results/psq3_alpha/result.json`. Adapter: `experiments/results/psq3_alpha/adapter_seed42/` (deleted; LoRA weights gitignored). Ledger: `psq3_alpha_result`.

## PSQ-3μ — frozen-model necessary-condition micro-test (2026-08-31; CLOSED NO_INTERFACE)

One-action necessary-condition intervention test on frozen Qwen3-0.6B-Base (CPU only, x-channel probes, S_μ = Z_8 × {0,2,4,6}).

- **Result:** 26.56% accuracy (68/256), gate >=95%. **NO_INTERFACE.** Stopped at stage 1 (256/1,152 calls, 132.6s CPU).
- **Disposition:** per predeclared stop rule, no repair; does not adjudicate full PSQ-3. Audit #49 adopted.
- Runner: `experiments/run_psq3.py`. Config: `experiments/config/psq3_micro_cpu.json`. Result: `experiments/results/psq3_micro_cpu/result.json`. Ledger: `psq3_micro_cpu`.

## PSQ-2 — LoRA fine-tuning for modular state tracking + d_4 geometry measurement (2026-08-30; CLOSED — Codex direction review: STOP hyperparameter staircase)

Two-dial world Z_8×Z_8 (64 states, 4 actions, 2 binary observations). H*=4 (Moore partition saturates at 64 = all states distinguishable). d_4 = d_∞ for this finite world (Corollary 3).

- **PSQ-2 v1** (single-step training only, 512 examples, lr=5e-5, 3 epochs): 60.2% overall, **NO_INTERFACE**. Model learned "not zero" bias (87.5% of training had answer=0). Per-step degradation: 81.2% at 2-step → 40.0% at 8-step. Config: `psq2_v1.json`. Result: `psq2_v1/finetune_and_gate.json`.
- **PSQ-2 v2** (class-balanced 1-3 step, 512 examples, lr=3e-5, 5 epochs, test OOD 4-8 step): 73.4% overall, **NO_INTERFACE**. Per-cell: x_0=65.6%, x_1=84.4%, y_0=62.5%, y_1=81.2%. Length degradation: 86.4% at 4-step → 56.0% at 8-step. Composition doesn't generalize from short to long. Config: `psq2_v2.json`. Result: `psq2_v2/finetune_and_gate.json`.
- **PSQ-2 v3** (class-balanced ALL 1-8 step, 1536 examples, lr=2e-5, 5 epochs, in-distribution test): 75.0% overall, **NO_INTERFACE**. Per-step: 1-step 100%, 2-step 100%, 3-step 78.3%, 4-step 85.7%, 5-step 77.8%, 6-step 46.7%, 7-step 60.0%, 8-step 63.2%. Model learns basic modular operations perfectly but can't compose 6+ steps. Worse on long sequences than v2's OOD (lower lr + diluted data). Config: `psq2_v3.json`. Result: `psq2_v3/finetune_and_gate.json`.
- **Exploratory d_4** (psq2_v3_d4): COMPLETE (DIAGNOSTIC ONLY per Codex direction review). d_4 measurement on v3 adapter at 75% accuracy: rho_model_oracle=0.579, rho_hidden_d4 L6/L12/L18 = 0.259/0.277/0.505, quasiconvex violations L18 = 4.6%. Sub-gate exploratory, not a scientific claim. Config: `psq2_v3_d4.json`. Result: `psq2_v3_d4/d4_measurement.json`.

- **Codex direction review (PSQ-2 round 1)**: Identified metric mismatch (max √JS degenerate for binary oracle), tautological causal test, invalid quasiconvexity surrogate, structured noise. Verdict: STOP hyperparameter staircase. Redesign as PSQ-3 with product metric d_{2,4}, shared Procrustes operators, calibration/held-out split.
- All runs: Qwen3-1.7B-Base (revision `ea980cb0a6c2ae4b936e82123acc929f1cec04c1`), LoRA r=16 alpha=32. Runner: `experiments/run_psq2_finetune.py`. d_4 runner: `experiments/run_psq1_d4.py`.

## PSQ-1 — few-shot capability screen: ALL SUBSTRATES NO_INTERFACE (2026-08-30; CLOSED)

Two-dial world Z_8×Z_8 with 4-shot Python-completion template. All three substrates failed:

- **Qwen3-1.7B-Base**: 50.0% (always predicts "1"). NO_INTERFACE.
- **Qwen3-8B-Base**: 55.5% (same bias). NO_INTERFACE.
- **Qwen3-8B-Instruct**: 50.0% (4-shot) / 64.1% (balanced 2-shot). NO_INTERFACE.

Root cause: models cannot do multi-step modular wrap-around arithmetic from few-shot prompting. This motivated PSQ-2 (fine-tuning approach). Runner: `experiments/run_psq1_capability.py`. Configs: `psq1_*.json`.

## register_bridge_preflight_v1 — noncausal real-model feasibility measurement: PREFLIGHT PASS — EXPLICIT-LEGEND STATE LINEARLY DECODABLE (audit #39: UPHOLD; noncausal feasibility result, not a code-level or causal bridge) (2026-08-30; audit #39 adopted verbatim)

- **Licensed sentence (audit #39, verbatim).** In frozen Qwen3-1.7B-Base revision `ea980cb0a6c2ae4b936e82123acc929f1cec04c1`, a predeclared rank-≤8 cross-fitted linear decoder read the explicitly legend-denoted state from the two-token record-tag residual under held-out entities, two held-out templates, and a disjoint balanced permutation bank at 0.815 accuracy (folds 0.828/0.852/0.766, entity-bootstrap lower bound 0.779, minimum state recall 0.615), versus 0.125 input-embedding, 0.135 categorical, and 0.016 paired reassigned-legend original-state controls and a 0.204 shuffle-null p99; on the paired reassigned legends the unchanged-tag decoder followed the newly denoted state at 0.852, establishing a noncausal, prompt-family-bounded explicit-legend state signal—not a code-level or causal bridge, persistent register, synthetic-consumer capability, or native latent mathematics.
- **Never say (audit #39).** “Qwen learned a register.” “This establishes a causal bridge.” “The Qwen residual already contains the constructed consumer’s code.” “The state survived, persisted, or was remembered.” “The result establishes an eight-dimensional state subspace.” “The decoder reads tag identity.” “The destroyed arm contains no state information.” “The destroyed context failed.” “Template and permutation transfer were independently established.” “The result generalizes to arbitrary templates, legends, or permutations.” “The shuffle null reran the entire selection pipeline.” “The bootstrap includes decoder-training uncertainty.” “Every layer contains the signal.” “The legend-occurrence reference is a gated control.” “The residuals can drive the frozen synthetic consumer.” “This demonstrates semantic facts, an autonomous state, or native latent mathematics.”
- **Restart ruling (audit #39, verbatim).** **Continue conditionally; the predeclared PASS branch should apply.** The highest-leverage next move is the required 2–3-round direction dialogue followed by one held-out causal bridge test: map Qwen record-span residuals into the successful writer centroids and inject them into the frozen constructed consumer. The program should not continue through another synthetic rung, decoder characterization round, layer sweep, or prompt repair. The current pause remains appropriate until the dialogue produces a locked causal test. The program is still tunnel-visioned around an eight-symbol explicit-lookup micro-world. The PASS justifies one causal discriminator; it does not justify extending the ladder indefinitely.
- Evidence: `run_result.json`, `run_rows.json` (per-row prompts, ids, spans, predictions), `run_features.npz` (local only; sha256 in the ledger result row).

## necessary_register_rung1 — constructed substrate, rung 1 (zero-delay training-entity source writer; replayed rung-0 consumers): QUALIFIED PASS — ANSWER-SUPERVISED EIGHT-SYMBOL WRITER INTO A FROZEN SYNTHETIC CONSUMER (audit #38 adopted `d4b82b7`; wording in `STATE.md`) (2026-08-30; locked `ea2e831`; runner `experiments/run_necessary_register.py`, config `experiments/config/necessary_register_rung1.json`, results `experiments/results/necessary_register_rung1/`; ledger `necessary_register_rung1_lock`, `necessary_register_rung1_result`)

Audit #38's exact licensed sentence, qualifications, and never-say list are reproduced in `STATE.md`'s Current statement. The synthetic staircase stopped after this rung; the only subsequent action was the separately locked noncausal preflight, now governed by audit #39.

## necessary_register_v1 — constructed substrate, rung 0 (oracle write, hard-masked register, unseen label permutations): QUALIFIED INSTRUMENT PASS — PERMUTATION-GENERALIZING ORACLE-CODE LABEL SELECTOR (2026-08-30; audit #37 adopted verbatim `abee584`; runner `experiments/run_necessary_register.py`, config `experiments/config/necessary_register_v1.json`, results `experiments/results/necessary_register_v1/`; commits `805bce2`, `e35b836`, `be28305`, `ff6c42b`, `abee584`)

STATE.md wording, verbatim:

- `necessary_register_v1` rung 0 — QUALIFIED INSTRUMENT PASS. The locked scalar gates mechanically passed in seeds 11/23/37, with own-code first-label accuracy 0.955/1.000/1.000 and same-prompt all-seven counterfactual following 0.962/1.000/1.000 on globally unseen state-to-label permutations. The result establishes a learned synthetic permutation-generalizing oracle-code-to-visible-label consumer, not general composition, source writing, persistence, or pretrained-model structure. Qualification: state/template/panel evaluation was marginally rather than factorially balanced; zero/random results are assigned-target accuracies only; zero-hook is decoded-state identity; and termination/raw rows were not retained for every arm. NEXT: one zero-delay training-entity writer rung, with fully crossed evaluation and complete evidence retention, alongside a cheap real-model source-span bridge-feasibility preflight; then audit once and stop on failure.

Licensed sentence (audit #37): In this locked synthetic task, three independently initialized two-layer causal transformers trained from scratch used fixed orthonormal vectors injected at a dedicated register position to select the intended abstract state under globally unseen visible state-to-label permutations, with own-code first-label accuracy 0.955/1.000/1.000 and all-seven same-prompt counterfactual-code following 0.962/1.000/1.000; this establishes a learned permutation-generalizing oracle-code-to-visible-label consumer for the tested schedule, not general compositional reasoning, learned writing or persistence, a fully crossed presentation-invariance result, or structure in a pretrained model.

Never say (audit #37): “The model learned compositional reasoning.” “No lookup strategy can pass the held-out gate.” “The evaluation fully crossed every state, panel, and template.” “Zero and random codes had no systematic effect.” “Zero/random-code behavior was at chance” without “assigned-target accuracy.” “Zero-hook proved exact logit-level identity” or “zero-hook equals the zero-vector arm.” “The mask proved that source information flows only through the register.” “Seed 11 was uniformly robust across presentations.” “The register learned to write, retain, or retrieve state.” “This establishes an abstract state representation in a pretrained model.” “The constructed ladder will transfer to Qwen.” “Instrument valid” without the synthetic, first-label, schedule, and evidence-retention qualifications.

- NEXT (historical; superseded by the rung-1 entry above): `necessary_register_rung1` (round 26 spec + audit #37 requirements: replay/freeze the rung-0 consumers, answer-only source writer at zero configured filler, fully crossed evaluation, raw rows, checkpoints, per-arm termination, logit-level identity, paired clustered uplift, lookup baselines) → one audit → direction dialogue on moving `register_bridge_v1` earlier vs short delay. Alongside (not staircase advancement): a cheap CPU real-model source-span linear-decodability preflight with token/context and shuffled-coordinate controls. Failure closes the constructed architecture; a lookup-only pass also stops advancement. Moves, algebra, effort, maps, long delay, larger models, the navigator and any block-12 actuator stay off.

## oracle_actuator_rung0 — positive-control staircase rung 0 (oracle code, no encoder; actuator/site/retrieval control): REGISTERED FAIL, unanimous; audit #34 ADOPTED (2026-08-30; ledger `direction_r20_rung0_design`, `oracle_actuator_rung0_preflight`, `oracle_actuator_rung0_lock`, `oracle_actuator_rung0_seed11`, `oracle_actuator_rung0_result`, `oracle_actuator_rung0_diag`; commits `2939d39`, `2ed1f5a`, `3a66506`, `0576717`, `c986668`, `aaba738`, `df8827e`)

- **Why (audit #33 + rung-0 localization; Codex round 20).** Rung 1 failed

and its failure was not localized among encoder, actuator, cap, site,

propagation and decoding; the localization check found only weak tag

information at the chosen source anchor. Round 20 removed the encoder

entirely: can a *known* hidden code, written once through a trainable

linear map, make the frozen model recall its matching tag?

- **Lock (`0576717`; ledger `oracle_actuator_rung0_lock`).** Runner

`experiments/run_oracle_actuator.py` (70 nonblank lines; cap telemetry

added to the shared write hook), config

`experiments/config/oracle_actuator_rung0.json` (config/module/machinery sha256 in the ledger row). Frozen Qwen3-1.7B-Base, block 12, final-token `Internal record:` slot; fixed immutable hashed codebook of eight unit centred-simplex codes c_k = sqrt(8/7)(e_k − 1/8, 0_8) (hash `3f2381fe…`); only a zero-init biasless J (16→2048) trained 400 balanced entity×code steps, lr 3e-3, seeds 11/23/37; 0.25×slot-norm cap in primary with per-step and per-row telemetry; one uncapped replay of the frozen J as diagnostic. Eval per seed: 24 training entities × 8 codes (own code = the entity's assigned code; the other 7 = wrong codes) + cue + zero-hook + 8 fixed off-code unit random vectors; training query wording, zero configured filler (~36 prompt tokens; never "zero delay"); entities = bootstrap clusters. Gates per seed: completion >= 0.95 (code/wrong/random); code-follow >= 0.85 (LB > 0.75; >= 0.75 per code); own-code >= 0.85; wrong-code follow >= 0.85 over 168 rows with uplift >= 0.65 over the cue matching rate (LB > 0.50); cue and random true-tag <= 0.20; own − random >= 0.60 (LB > 0.50); zero-hook = cue row-for-row; every gate in >= 2 of 3 seeds. Statuses: `BOUNDED ACTUATOR PASS — ORACLE CODE` / `CAP-LIMITED ACTUATOR` (uncapped passes, capped fails) / `FAIL — ORACLE ACTUATOR/SITE/RETRIEVAL CONSTRUCTION` (both fail; this J/site/retrieval line stops). No repair run.

 **Preflight (eight zero-J rows only; `experiments/results/onewrite_recall_rung1/oracle_preflight.log`): PASS** — codebook Gram diag 1.0, off-diagonal −0.143; hook fires once per hooked prefill; pre-cap ‖Jc‖ = 0 on all rows; zero-hook = cue on 8/8. (A first pass reported FAIL only because it read the hook counter after a cue decode had reset it; the corrected run is the record.)

 **Result (`experiments/results/oracle_actuator_rung0/run_result.json`; `J_seed{11,23,37}.pt`; 2903 s; ledger `oracle_actuator_rung0_result`).** `FAIL — ORACLE ACTUATOR/SITE/RETRIEVAL CONSTRUCTION`; capped passes 0/3, uncapped passes 0/3. Cap never active in any seed (pre-cap ‖Jc‖ <= 14 vs threshold 43), so capped and uncapped evaluations are identical. Code-follow 0.219/0.245/0.245; per code: code 0 0.96/0.96/0.96, code 6 0.75/0.96/0.96, codes 1–5 0.0, code 7 0.04 in every seed; own-code 0.25 in every seed; wrong-code follow 0.21/0.24/0.24 (uplift 0.10/0.125/0.125 over the cue matching rate); cue true-tag 0.125 (the cue decode is the base prior `fask`, code 0's tag); random-vector true-tag 0.13/0.13/0.125; completion 0.96 in code/random/cue arms; zero-hook = cue row-for-row; training loss flat 1.5–1.75.

 **Read-only diagnostic on the saved J's (ledger `oracle_actuator_rung0_diag`; `diag_logit_lens.log`).** The eight write vectors J c_k are near-orthogonal (mean pairwise cosine −0.14) with norms 12–23; the raw logit lens of each write does not point at the code's tag (own-tag first-token rank ~10^5 of 151k in all codes and seeds); late-training loss by code: code 0 1.20–1.22, code 6 1.41–1.56, all others 1.59–2.10; every tag is two tokens with distinct first tokens. Diagnostic only; feeds audit #34.

- **Status.** Registered FAIL; audit #34 (fresh, unprimed) ADOPTED — licensed sentence and never-say list verbatim in `STATE.md` (ledger `oracle_actuator_rung0_audit34`).

## onewrite_recall_rung1 — positive-control staircase rung 1 (training entities, training wording, zero configured filler): REGISTERED CONSTRUCTION-LEVEL FAIL, CLOSED (2026-08-29 night; unanimous seeds 11/23/37; ledger `direction_r19_ruling`, `onewrite_recall_rung1_lock`, `onewrite_recall_rung1_result`, `onewrite_recall_rung1_rung0_diag`, `onewrite_recall_rung1_audit33`, `onewrite_recall_rung1_z_localization`; commits `c71d44a`, `15758aa`, `9c14c7b`, `25f65ac`, `844676b`)

- **Why (governance amendment 8, `AGENTS.md`; audit #32).** The common explanation of the day's closures is that bespoke instruments and actuators were changed before the proximal mechanism was shown learnable (the v1 interface never learned tag identity even on training entities: own-write 4/24, own vs counterfactual outputs identical 24/24). The loop now keeps one cumulative artifact and climbs a staircase: (i) own-write vs same-entity counterfactual specificity on training items at zero delay; (ii) zero/short delay; (iii) held-out names; (iv) unseen wording; (v) long delay — one difficulty per rung, each locked, run and audited once. Replaces "one locked artifact per day".

- **Lock (Codex round 19).** Same runner `experiments/run_onewrite_recall.py` and one-write machinery as v1 (frozen Qwen3-1.7B-Base, E/J interface, block-12 slot write, strict decoding, 8 tags, same-entity counterfactual donors); config `experiments/config/onewrite_recall_rung1.json`. Every later difficulty removed: 24 TRAINING entities, training wording `TAG OF {NAME}:`, zero intervening tokens (target = slot + VALID TAGS line + query); 24 entities x 2 training source phrasings = 48 cases per arm per seed; arms write/cue/zero-hook/wrong/random/visible; gates unchanged from v1 (write >= 0.75; write − cue >= 0.50, LB > 0.30; write − random >= 0.50, LB > 0.30; random <= 0.20; recovery >= 0.60; per-source >= 0.70; counterfactual follow >= 0.60 and >= 0.40 over the cue-cf rate; completion >= 0.95 in write/wrong/random/visible; zero-hook = cue row-for-row).

- **Pre-lock validation PASS** (`experiments/results/onewrite_recall_rung1/validate_result.json`): visible 1.0, cue 0.125 (chance), visible completion 1.0, cue completion 0.96, zero-hook = cue. No outcome inspected before the lock.

- **Rule.** If rung 1 fails, this interface stops without testing later rungs; if it passes, the next rung changes exactly one difficulty.

- **Result (`experiments/results/onewrite_recall_rung1/train_result.json`; `iface_seed{11,23,37}.pt`; 1820 s; ledger `onewrite_recall_rung1_result`, `15758aa`).** Unanimous FAIL. Visible 1.0; cue 0.125 (chance); own write 0.167/0.188/0.292 (8/48, 9/48, 14/48) vs same-entity counterfactual write 0.167/0.188/0.271 (8/48, 9/48, 13/48) vs fixed random write 0.167/0.208/0.333 (8/48, 10/48, 16/48); counterfactual follow 0.083/0.167/0.167; completion 1.0 under any write, 0.96 cue; zero-hook = cue row-for-row; single-example loss 2.2/1.6/2.2 -> ~1.0. The interface stops under the round-19 rule.

 **Audit #33 (fresh, unprimed; `.codex_audit33.md`; adopted verbatim `25f65ac`; ledger `onewrite_recall_rung1_audit33`).** FAIL upheld. My "learns no fact-specific control" was withdrawn as unqualified (own and counterfactual writes changed the greedy tag on 6/144 paired rows; no pair followed both intended directions; own write never beat the fixed random write; each seed emitted only 4 of 8 tags); "zero delay" withdrawn (36 prompt tokens of VALID TAGS/instruction block separate slot and query — say "zero configured filler"); the loss near 1.0 is the two-token chance-first-token null (1.04), not learned tag identity; evaluation used 2 of 3 training source templates; failure NOT localized among encoder, actuator, cap, site, propagation, decoding. Program: stop this interface family; run one no-training localization check on the saved encoders; keep the navigator deferred.

 **Licensed sentence (audit #33, verbatim):** `onewrite_recall_rung1` is a unanimous registered construction-level FAIL: in frozen Qwen3-1.7B-Base, on 24 training entities evaluated under two of the three training source templates, the training query wording, and zero configured filler, own-write true-tag accuracy was 0.167/0.188/0.292 across seeds 11/23/37, versus 0.167/0.188/0.271 for same-entity counterfactual-tag writes and 0.167/0.208/0.333 for one fixed random write; own and counterfactual writes changed the greedy tag on 6/144 paired rows, but no pair simultaneously followed the true and counterfactual tags, so this exact 65,552-parameter linear E/J, generic block-12 slot, 0.25-norm-capped, 400-step construction did not establish reliable control-relative tag recall and stops under its predeclared rule.

 **Never say (audit #33, verbatim):** “The interface learns no fact-specific control,” without specifying the registered construction and greedy readout. “Correct and counterfactual writes are identical row-for-row.” “There is no tag-specific effect at all.” “The loss implies about 35–38% correct-tag probability.” “The training loss proves that `E` learned tag identity.” “This was a literal zero-delay or immediate-query test.” “All training source phrasings were evaluated.” “The fixed random arm rules out random interventions generally.” “The 0.25 cap was adequate” or “the cap caused the failure.” “The encoder failed,” “the writer failed,” or “the state was written but could not be retrieved.” “A linear one-write channel, block 12, a 16-dimensional state, or frozen-model memory is unlearnable.” “This establishes that current pretrained latent spaces are hostile to structured reasoning.” “This closes the real-model program.”

 **Rung-0 localization on the saved encoders (read-only; ledger `onewrite_recall_rung1_rung0_diag`, `onewrite_recall_rung1_z_localization`; `z_localization.log`; `9c14c7b`, `844676b`).** Entity-grouped, source-template-held-out nearest-centroid tag accuracy: raw block-12 residual at the final ` Internal record:` source token 0.340 (shuffled 95th pct 0.181; chance 0.125); learned z = E(LN(h)) 0.333/0.153/0.194 (random 16-d projection 0.17/0.23/0.19); earlier leave-one-out on training

sources 0.36/0.14/0.12; write lift of the correct tag +1.36/+1.42/+1.56 nats vs counterfactual-tag lift +1.27/+1.31/+1.29; pre-cap |Jz| ~1900–2100 against the 0.25×slot-norm cap. Recorded branch (ledger, not audited wording): the tag signal at the chosen source anchor is weak and the encoder recovers at most that signal; downstream stages untested. Led to Codex round 20 (oracle-code actuator rung 0; entry above).

## necessity_navigator_v1 — audit-#32 blockers fixed; post-fix smoke (code-path validation, NOT a result); comparator rule; DEFERRED (2026-08-29 night; ledger `navigator_smoke_r32fixes`, `direction_r19_ruling`; commits `faa7a64`, `c71d44a`)

- **Fixes (`faa7a64`).** Swap rollout continues from the donor state with the NEXT step's input (no duplicated step); manifest hash binds goal words, permutation triples, times, walk actions and poses; untrained controls on identical inputs; comparator per the lock text.
- **Smoke (2000 steps, seed 11, reduced readouts; `experiments/results/necessity_navigator_v1/smoke_result.json`; NOT a result).** Held-out top-1 in A* 0.879 vs historyless control 0.484 (valid). Causal swap: donor recurrent state inserted into a recipient episode under a different symbol permutation moves behaviour to the donor place — swap 0.90 vs noswap 0.47 / wrong-place 0.41 / random 0.44; self reference 0.9025; decision-4 0.90. Structural readouts fail: moves R 0.24 (untrained same-input control 0.48); composition order accuracy 0.51 (chance), commuting ratio 2.1; inverse ratio 0.63 (untrained 0.90); distance Spearman 0.30. With self in the comparator the uplift is −0.0025 by construction; referred to round 19.
- **Round 19 comparator rule (ledger `direction_r19_ruling`; config `experiments/config/necessity_navigator_v1.json`, `c71d44a`).** `self` is the oracle ceiling, excluded from both uplift comparators; locked swap rule: swap >= 0.75; decision-4 >= 0.65; swap − max(noswap, wrong-place, random) >= 0.25; mass uplift >= 0.50 over the same three; swap/self >= 0.80; self reported as ceiling. All other gates, controls, seeds (3 x 4000 steps) and status rules unchanged. Resolves an ambiguity in the lock; rescues nothing.
- **Status: DEFERRED, not cancelled** — governance amendment 8 puts the real-model proximal mechanism (rung 1) first; runs only after a direction dialogue; no v2. Licensed user sentence (round 19, verbatim): "In a non-registered 2,000-step smoke, the navigator's recurrent state transferred across a new symbol permutation and drove donor-place behavior at 0.90 accuracy—essentially matching the 0.9025 self ceiling and exceeding no-swap, wrong-place, and random controls—but this validates only the causal-swap instrument, not learned latent algebra or a navigator result, because composition remained at chance at 0.51 and the four structural readouts failed."

## onewrite_recall_v1 — REGISTERED CONSTRUCTION-LEVEL FAIL, CLOSED (2026-08-29 night; unanimous seeds 11/23/37; ledger `direction_r17_amendment`, `onewrite_recall_v1_lock`, `onewrite_recall_v1_seed11`, `direction_r18_ruling`,

## `onewrite_recall_v1_result`, `onewrite_recall_v1_audit32`; audit #32 adopted verbatim `3a47fd8`)

- **Lock (rounds 15–17; `1f2fcba`).** Round 17 amended the pre-lock protocol gate (cue completion diagnostic with no minimum; zero-hook must reproduce cue row-for-row else INVALID — NO VERDICT); validation PASS: visible 1.0 (A 1.0, B 1.0), visible completion 1.0, cue 0.0, cue completion 0.031. Three seeds 11/23/37, 400 single-example steps each; 64 cases per arm per seed (16 heldout entities x 2 source phrasings x 2 target wordings); arms write/cue/zero-hook/wrong/random/visible.

- **Result (`experiments/results/onewrite_recall_v1/train_result.json`; 4094 s).** Per seed, held-out raw recall after the one write 0.031/0.031/0.0625 = counterfactual-write = random-write; cue 0.0; visible-copy 1.0; completion under any learned write 0.44/0.53/0.42 (content-independent tag-shaped nudge), cue/zero-hook 0.03; counterfactual follow 0.16/0.13/0.16; zero-hook reproduces cue row-for-row in all seeds (valid). Audit #32 replay: correct/counterfactual/random writes produced identical raw text on 64/64 rows in seeds 11 and 23 and identical choices on 64/64 (raw 62/64) in seed 37; no correct-tag signal below the parser. Post-hoc seed-11 training-slice diagnostic: own-write 4/24, cue 2/24, own vs counterfactual-source outputs identical 24/24 (diagnostic, not a result).

- **Licensed sentence (audit #32, verbatim):** Under the round-17-amended behavioral readout—visible-copy accuracy 1.00 and cue accuracy 0.00—`onewrite_recall_v1` was a unanimous construction-level FAIL: across seeds 11, 23, and 37, the correct-source intervention achieved held-out tag accuracy 0.031, 0.031, and 0.0625, respectively, exactly matching the same-entity counterfactual-tag and fixed-random arms within each seed, while valid-tag emission rose nonspecifically from 0.031 in cue to 0.438, 0.531, and 0.422; therefore this 65,552-parameter, 16-dimensional encoder/injector, trained for 400 single-example steps and applied once at the norm-capped block-12 slot before the registered filler/instruction/query sequence, did not establish a held-out causal tag-recall channel.

- **Never say (audit #32, verbatim):** “The fact was written but did not survive.” “The experiment proved that the model cannot store a fact in hidden state.” “Block 12 cannot support persistent memory.” “A 16-dimensional or 65,552-parameter interface is insufficient in principle.” “The 71–73 filler tokens are the complete write-to-query delay.” “All three seeds scored 0.031.” “The training loss proves that the train facts or tag identities were learned.” “Correct and counterfactual writes had identical raw text in all three seeds.” Their choices did; seed 37 had two non-tag raw-text differences. “Random controls rule out every useful intervention.” Only one fixed random state per seed was tested. “The intervention had no effect.” It strongly changed valid-tag emission. “The write was content-independent” without the construction qualifier; only its

saved downstream choices were nonspecific under these arms. “The original preregistered instrument passed.” It passed the outcome-aware but pre-training round-17 amendment. “More steps, another layer, a different slot, a maintained state, or another objective would also fail.” “Frozen language models lack native state or latent mathematics.” “This closes the real-model route.”

 **Rounds 18–19.** Round 18 (ledger `direction_r18_ruling`) read the result as a clean negative on a valid instrument for the registered construction only and licensed one navigator calibration run; its sentence is superseded by audit #32 above. Round 19 (ledger `direction_r19_ruling`) deferred the navigator and moved the one-write line to the staircase (rung 1 above). Design and pre-lock history: next entry.

## onewrite_recall_v1 — design and pre-lock record (2026-08-29; ledger `direction_r15_ruling`, `onewrite_recall_v1_validation`, `direction_r16_recall_gates`, `onewrite_recall_v1_validation_r16`; result entry above)

 **Design (Codex direction round 15; gates and amendments round 16).** Runner `experiments/run_onewrite_recall.py`, config `experiments/config/onewrite_recall_v1.json` (`95fb53e`, amendments `c1486f1`). Source `The private tag assigned to {name} is {tag}.` -> one write of a 16-d code at block 12 at the slot's final token -> unseen target wording (`PRIVATE TAG FOR {NAME}:`) after two fixed fillers of >= 64 tokens; endpoint = the raw decoded tag; 8 nonce tags (3 train + 2 heldout facts per tag; chance 0.125); canonical VALID TAGS line in every target; arms visible-copy / cue-only / correct-write / wrong-donor (counterfactual tag by balanced derangement) / random / zero-hook; byte-identical nonvisible target across arms. A positive would license only: "a co-designed interface can write one factual value once into a frozen real model and recover it after unseen wording" — a persistent causal memory channel, not abstraction, transfer, native state, or latent mathematics. Result gates (round 16): write >= 0.75; write − cue >= 0.50 (LB > 0.30); write − random >= 0.50 (LB > 0.30); random <= 0.20; recovery >= 0.60; per-phrasing/wording write >= 0.70 with gaps <= 0.15; wrong-state follows its counterfactual tag >= 0.60 and exceeds the cue rate by >= 0.40; completion >= 0.95 in all six arms; zero-hook must reproduce cue row-for-row else INVALID — NO VERDICT; no repair run.

 **Pre-lock validation 1 (provisional gates; no state; `experiments/results/onewrite_recall_v1/validate.log`):** 16 heldout entities x 2 wordings, 16 tags: visible-copy 0.906 (A 0.875, B 0.938), visible completion 0.906; cue accuracy 0.0, cue completion 0.0.

 **Pre-lock validation 2 (round-16 locked gate; no state; `experiments/results/onewrite_recall_v1/validate_result.json`):** visible-copy accuracy 1.0 (A 1.0, B 1.0), visible completion 1.0; cue accuracy 0.0 (both wordings); visible − cue = 1.0; cue completion 0.031 (without the fact the model emits `100`/`123`, not a listed tag, despite

the VALID TAGS line). By the letter of the gate (`cue completion >= 0.95`) this is a pre-lock FAIL on a protocol criterion orthogonal to the state hypothesis while the substantive instrument (visible 1.0 vs cue 0.0) is perfect. **Not locked; referred to Codex round 17** (kill by the letter, or amend the protocol criterion pre-lock). No training run; nothing licensed.

## onewrite_state_v1 — one-write persistent state on frozen Qwen3-1.7B-Base: KILLED PRE-LOCK (2026-08-29; ledger `direction_r13_onewrite_design`, `onewrite_state_v1_smoke`, `direction_r14_instrument`, `onewrite_state_v1_killed_prelock`)

- **Design (Codex direction round 13, locked; `experiments/run_onewrite_state.py`, `experiments/config/onewrite_state_v1.json`, `b7991dc`).** Train only E (2048->16) and J (16->2048), 65,552 params; one write at block 12 to the final token of an early `Internal record:` slot, clamp ||Jz|| <= 0.25 ||h_slot||; 40 invented entities over three binary nonce attributes; trained consequence families PORT/VAULT, NORTH/SOUTH, RING/STAR; heldout families H1 (XOR -> CEDAR/QUARTZ) and H2 (attr2 x attr3 -> four labels) with labels and templates absent from training; arms correct-write / cue-only / wrong-state / random / visible-text ceiling; raw decoded choices only.
- **Smoke (60 steps, seed 11; `experiments/results/onewrite_state_v1/smoke.log`; not a result):** behavioural instrument invalid before any state question — visible-text ceiling 0.27 (gate >= 0.80), termination 0.17; cue 0.20; write 0.39 = wrong 0.39 = random 0.39 (a non-specific format effect). Referred to Codex round 14, which allowed ONE instrument repair (terse FORMAT EXAMPLE / TEST CASE / NEW ITEM format, strict first-item parsing) and pre-declared the kill sentence.
- **Sole pre-lock validation (round-14 format; no state; 64 heldout cases; `experiments/results/onewrite_state_v1/validate_result.json`):** visible-tag accuracy 0.344 (H1 0.50, H2 0.19; wording A 0.31, B 0.38) = cue accuracy 0.344; completion 1.0 in both arms — the model always emits an allowed label but ignores whether the tags are shown. Gate (visible >= 0.80, visible − cue >= 0.30) FAILED. **Pre-declared ruling (Codex round 14, verbatim):** onewrite_state_v1 is killed pre-lock because Qwen3-1.7B-Base could not support the registered behavioral instrument even when the facts were visible; no state hypothesis was tested. Side probe (`instrument_probe.log`, `instrument_probe_4b.log`): Qwen3-4B-Base is also at chance on the H1/H2 two-variable tables (0.44/0.31 terse; 0.50/0.56 one-shot) while managing a one-attribute rule at 0.81. No training run; no prompt iteration or model substitution (pre-declared). Untracked smoke artifacts (`iface_seed11.pt`, `smoke_result.json`) are local only.
- **What we learned:** the discovered constraint is instrument validity — the tested Qwen3 bases through 4B cannot reliably apply a two-variable table to visible facts, so rule-dependent behavioral readouts cannot adjudicate hidden-state interventions at this scale (round 15).

## necessity_navigator_v1 — from-scratch navigator on Z_11^2 □ C_4 with aliased, per-episode-permuted observations: BUILT, smoke-tested; optional one-round calibration control; UNRUN (2026-08-29; ledger `direction_r11_navigator_design`, `direction_r12_ruling`)

□ **Design (Codex direction round 11).** GRU hidden 64 (~17.7k params); 8 observation classes over 121 positions with per-episode S_8 symbol permutation from disjoint banks; goal-word episodes with BFS-optimal action sets; historyless Bayes control; behavioural validity = held-out top-1 membership >= 0.85 and >= 0.20 above the control; five approximate readouts on held-out permutations (moves, composition/noncommutativity, inverses, reachability distance, causal state swap); statuses BOUNDED POSITIVE / PARTIAL / FAIL; no v1r2. Runner `experiments/run_necessity_navigator.py` (196 nonblank lines), config `experiments/config/necessity_navigator_v1.json` (`ab758ec`).

□ **Smoke (2000 steps, seed 11; code-path validation, not a result; `experiments/results/necessity_navigator_v1/smoke_result.json`, untracked):** held-out top-1 in A* 0.879 vs historyless control 0.484; readouts execute — moves R 0.243 (untrained-GRU control 0.383), composition order accuracy 0.509, inverse ratio 0.629, distance Spearman 0.296; the swap pairing needs same-goal episodes across permutations if it is ever run.

□ **Status (round 12 amendment, round 15):** optional one-round calibration control, not the central artifact; do not run before a real-model result; runs once only if direct recall is valid but donor-specific persistence fails; if run and >= 2 seeds are behaviourally valid but composition and swap both fail, close the hypothesis that task necessity alone yields a readable causally portable algebra; no repair of group/GRU/alias/optimizer/readouts.

## control_cost_v1 — minimum-energy span control, Qwen3-1.7B-Base block 12: REGISTERED CONSTRUCTION-LEVEL FAIL, CLOSED (2026-08-29; ledger `direction_r9_control_cost_design`, `control_cost_v1_lock`, `control_cost_v1_result`, `control_cost_v1_audit31_correction`)

□ **Design (Codex direction round 9; runner `experiments/run_control_cost.py`, config `experiments/config/control_cost_v1.json`, lock `f5aaf9f`).** One-time sigma-scaled field broadcast over the 23-token prefix span at block 12; first-order minimum-energy solve `v* = J^T (J J^T)^+ r` through the three-probe signature Jacobian at v=0; alpha grid {0, .25, .5, 1, 2, 4}; A readout (cat/dog probes) and B readout (unoptimized consequence); prompt-specific and shared fields; random-field and lexical controls.

□ **Result (`experiments/results/control_cost_v1/result.json`; `ff361bc`):** status `FAIL — FIXED BLOCK-12 SPAN CONTROL CONSTRUCTION`. Native A validity 23/24; native B validity 17/24 (cat 7/12, dog 10/12) -> B gates void. Prompt-specific first-order fields realized the A target in 1/8 recipients by alpha <= 4 (7 right-censored); shared fields attained A in 2/4 recipients per direction at alpha = 2.

□ **Audit #31 (fresh, unprimed; adopted verbatim `17b3d90`).** FAIL upheld; interpretation corrected: "the first-order minimum-energy law does not

hold", Spearman 0.76 (censored costs stored as 4x predicted, ranks inherited), median ratio 4.0 (a censoring boundary), cross-vs-within 8/8 (only 2 orderings identified), the semantic-B advantage (B invalid), "random fields move B just as much", and the directional cost asymmetry are all withdrawn as evidence. Licensed residue: the registered A readout responds causally and directionally to the constructed fields (mean dog->cat movement 0.28/0.40/0.54/0.67 vs cat->dog 0.04/0.11/0.14/0.16 at alpha .25/.5/1/2) — an actuator/readout-specific response asymmetry, not an effort geometry. **Licensed sentence (verbatim):** At fixed block 12 in Qwen3-1.7B-Base, the registered sigma-scaled uniform 23-token prefix-span field derived from the v=0 three-probe Jacobian attained the joint A endpoint in 1/8 held-out recipients by α≤4, while B was not a native-valid readout; because seven local costs and six within-class costs were right-censored, the saved data do not establish a realized-cost rank law, cross-versus-within effort geometry, semantic transfer, or directional cost asymmetry, so this closes the registered actuator/solver/readout/budget construction—not first-order control, span reachability, or latent effort generally.

- **Never say (audit #31):** “The first-order minimum-energy law does not hold.” “The model’s response is strongly nonlinear at the magnitudes needed” without naming the unresolved solver, scaling, actuator, and censoring alternatives. “Predicted cost ranked realized cost.” “The method underpredicted realized cost fourfold.” “Cross-class moves cost more than presentation changes.” “The semantic field transferred to unoptimized consequences.” “The semantic field beat lexical steering.” “`p=.008` establishes semantic structure.” “Random fields moved B just as much.” “Cat→dog is intrinsically cheaper than dog→cat.” “Span control failed” or “reachability failed” without the complete registered scope. “The preregistration was executed completely.” “Five independent interventions prove the substrate lacks native structure.” “Frozen residual streams cannot support structured reasoning.” “The next latent space must be trained” as a scientific conclusion rather than an allocation hypothesis.
- **What we learned:** construction family closed; no alpha/rcond/layer/span/probe/optimizer repair; ratio ~6.4:1; the broader question continues only after a substrate-level pivot (direction round 10).

## Direction rounds 10–17 (Codex direction dialogue, 2026-08-29 evening) — rulings

- **Round 10** (ledger `direction_r10_program_ruling`, `44c5507`): STOP POINT for the frozen-pretrained residual-stream line as constituted (six measurement rounds to one build round); not a proof that pretrained models lack latent mathematics; next artifact class = a constructive state-bearing substrate.
- **Round 11** (ledger `direction_r11_navigator_design`, `17b3d90`): `necessity_navigator_v1` locked design (entry above).
- **Round 12** (ledger `direction_r12_ruling`, `17b3d90`/`ab758ec`): reconciliation with audit #31's alternative — build the real-model one-write state artifact first; navigator demoted to an optional one-round calibration control.
- **Round 13** (ledger `direction_r13_onewrite_design`, `5934693`): `onewrite_state_v1` locked design (entry above).
- **Round 14** (ledger `direction_r14_instrument`, `9a2a54a`): one instrument repair for `onewrite_state_v1`, sole pre-lock validation, and the pre-declared kill sentence.
- **Round 15** (ledger `direction_r15_ruling`, `a31235e`; verbatim in NOTEBOOK): keep the kill; dominant problem = semantic instrumentation; next artifact `onewrite_recall_v1`; navigator not now.
- **Round 16** (ledger `direction_r16_recall_gates`, `95fb53e`): `onewrite_recall_v1` locked amendments and gates (entry above).
- **Round 17** (ledger `direction_r17_amendment`): amended the

`onewrite_recall_v1` pre-lock cue-completion criterion (cue completion diagnostic only; zero-hook must reproduce cue row-for-row); locked `1f2fcba` (result entry above).

## interchange_v2 — bias-controlled operational interchangeability, Qwen3-1.7B-Base block 12: REGISTERED CONSTRUCTION-LEVEL FAIL, CLOSED (2026-08-29; ledger `interchange_v2_lock`, `interchange_v2_result`; audit #30 adopted `fe3c541`)

- **Design (Codex direction round 8, `d069955`; runner `experiments/run_interchange.py` + config `experiments/config/interchange_v2.json`, locked `f7e3d18` with no outcome inspected; contexts re-matched `7beeb2b`).** Same Qwen3-1.7B-Base revision, CPU fp32, block 12, final anchor ` The animal`, coefficient-one replacement; fresh cat/dog calibration and held-out paraphrases, all exactly 25 tokens; fresh length-matched cow/horse contexts as on-manifold third-state donors; calibration-centred standardized probe statistic (removes the verbalizer bias that killed `interchange_v1`); fractional donor movement with squared-separation denominator; exact 2^8 recipient sign-flip specificity test. One construction; no v3.
- **Result** (`experiments/results/interchange_v2/result.json`; `65680e5`): native centred validity passed (cat 11/12, dog 12/12; gate met), same-state donors within tolerance 8/8 (median distance 0.35, tau 3.38), but replacing the block-12 anchor residual with the opposite class's anchor residual moved the three-probe signature by a median fractional 0.009 of the class separation with 0/8 recipients flipping two decisions; on-manifold cow/horse third-state donors moved recipients |T| 0.10–0.21 and the cross-vs-third specificity test was null (4/8 paired positive; exact sign-flip p = 0.47). Pre-declared status, verbatim: `FAIL — FIXED BLOCK-12 SINGLE-ANCHOR INTERCHANGE CONSTRUCTION` (480 forwards, 105 s). Gates: same_state True, cross_state False, specificity False.
- **Audit #30 (fresh, unprimed; ledger `interchange_v2_audit30_correction`; adopted verbatim `fe3c541`): REGISTERED CONSTRUCTION-LEVEL FAIL upheld; distributed-state and toward-neutral readings withdrawn.** The same-state gate is non-discriminating (every cross- and third-state arm also lies within tolerance); `p=.4727` is a descriptive sign-symmetry sensitivity, not an exact randomized test. **Licensed sentence (verbatim):** In Qwen3-1.7B-Base, with calibration-relative three-probe validity on 23/24 decisions, coefficient-one replacement of the block-12 residual at only the final generic ` The animal` token by matched opposite-class donors moved the standardized probe signature a median 0.0087 class separations and changed none of 24 probe signs across eight recipients, so `interchange_v2` fails its preregistered fixed single-anchor construction; because same-, cross-, and cow/horse third-state donor perturbations all fell within the same-state tolerance and the unchanged prefix remained causally available, this result does not establish absence of class information at the anchor, a distributed animal state, or failure of frozen-residual interchangeability outside this site, layer, coefficient, donor pairing, and readout.
- **Never say (audit #30):** “There is no class state at the anchor.” “The animal state lives across the prefix.” “The probes read the class from earlier tokens through attention” as an established mechanism. “Later layers overwrote the donor state.” “Block 12 is the wrong layer” as a result rather than a hypothesis. “Same-state interchangeability passed.” “Same-state signatures were preserved.” “Cow and horse donors moved both classes toward neutral.” “The exact `p=.47` proves no specificity.” “Interchangeability failed in Qwen3-1.7B-Base.” “Frozen residual streams lack native state or native mathematics.” “Persistent state must be trained.” “Native animal classification was 23/24” without “calibration-relative.” “Twenty-four independent decisions” or “three independent probes.” “The preregistration was executed completely”; the short decodes are absent.

## state_bus_v1r1 — result, audit-stage re-adjudication and audit #29: REGISTERED FAIL, CLOSED (2026-08-29; ledger `state_bus_v1r1_result`, `state_bus_v1r1_audit_stage`, `state_bus_v1r1_audit29`)

- **Registered result (`7beeb2b`; unanimous, seeds 11/23/37).** Stored

status `FAIL — same_swap, persistence`; `summary.fails` also records `heldout_consequence` in every seed. Per seed: same-swap outside the training-derived tau (0.268/0.377/0.228) on 16/15/16 rows while self and same-donor raw choice accuracy is 1.0 on all three decisions; cross uplift-consistent ≥2/3 on 15/16/16; heldout-taxonomy uplift-consistent 9/9/8 of 16 (gate ≥10), gain +0.34/+0.38/+0.19; taxonomy raw choice follows the donor on 7/16 in every seed; cross-consequence movement 12.2→9.8→2.9, 13.9→8.7→3.0, 11.9→7.3→3.1 nats; constrained own-choice rollouts all-donor on 15/16/15. Artifacts `experiments/results/state_bus_v1r1/result.json` (checkpoints and logs tracked at `bd1d9de`).

- **Audit-stage re-adjudication (`556b47c`; eval-only sensitivity beside the registered FAIL; 0.5-nat floor declared pre-result).** All-pair raw taxonomy donor choice 15/48, 14/48, 7/48; on-manifold wrong-code control 1/96, 1/96, 2/96; per-state recipients moved cat/dog/cow/horse = 1/0/2/0, 2/0/1/0, 0/0/0/0; class `FAIL` in all seeds (`experiments/results/state_bus_v1r1/audit_result.json`). Not a rescue.
- **Audit #29 (fresh, unprimed; adopted verbatim `4087742`).** FAIL upheld with corrections both ways: the status string omitted the registered heldout-taxonomy failure (control-flow defect, fixed post hoc in `experiments/run_state_bus.py` `verdict()`; stored results unchanged); categorical same-state behaviour transferred while fine-grained confidence signatures did not; the raw 7/16 is always cat→dog 3/4 and cow→horse 4/4 and every all-pair taxonomy success targets canine or equine only; the movement ratio is not an identified temporal decay. Pre-declared round-8 reading ("sequential semantic controller", "partial taxonomy transfer", "76% decay") withdrawn. **Licensed sentence (verbatim):** **`state_bus_v1r1` is a fixed-construction FAIL: a 98,400-parameter supervised interface repeatedly injected a 16-dimensional code into frozen Qwen3-1.7B-Base, and across three seeds held-out same-state donors preserved every four-way categorical choice but failed the training-derived confidence-signature tolerance on 15–16/16 rows, while fixed-cycle cross codes changed taxonomy choice on 7/16 rows—always cat→dog in 3/4 and cow→horse in 4/4—and the complete registered gate vector also failed heldout taxonomy and the cross-consequence third/first movement criterion; taxonomy verbalizers were absent from the bus loss, but the all-pair sensitivity was donor-verbalizer-specific rather than state-general, so the licensed residue is a repeatedly maintained supervised response controller with pair-specific lexical/semantic steering, not autonomous persistence, abstraction, general interchangeability, or native latent mathematics.**
- **Never say (audit #29):** "Partial taxonomy transfer" without "pair-specific" and the cat→dog/cow→horse concentration. "`7/16` beat chance" or "`9/16` is statistically significant." "Three independent semantic replications." "Same-state interchangeability failed." "Same-state confidence signatures generalized." "The state decayed by 76%." "The state survived through generation." "The bus learned autonomous persistence." "The rollouts freely generated all donor words." "The heldout consequence was unseen"; only its verbalizers were absent from the bus loss. "All four states" or "all donor pairs" transferred. "The controls rule out lexical or output-space steering." "Token length explains the whole effect." "Reader MSE proves a persistent readable state." "Trained-consequence accuracy was 1.0" without saying this is the self-code statistic. "Qwen learned the bus"; Qwen was frozen. "The bus establishes abstraction, interchangeability, or native latent mathematics." "This FAIL refutes co-developed interfaces or persistent state generally."
- **What we learned:** the bus construction and budget are closed; no bus v2. Strongest unified alternative for the day's real-model results (audit #29): the frozen model supplies a biased lexical-semantic response geometry within which late interventions and trained injection vectors move candidate-word likelihoods, with visible selected words mediating

later decisions — no persistent interchangeable state is needed. Ratio about 3.6:1 (runner-only) to 6.9:1 (with config and audit stage) exceeds both tripwires; pivot to reachability / control cost mandated.

## state_bus_v1r1 — design, lock and pre-outcome record (historical; 2026-08-29; ledger `state_bus_v1r1_lock`, `audit28`)

 **Design (Codex direction round 7, ledger `direction_r7_ruling`; runner `experiments/run_state_bus.py` `c64cd67`; config `experiments/config/state_bus_v1.json`).** Frozen Qwen3-1.7B-Base; block-12 16-d bus with <100k trainable parameters (encoder E, four prototypes, injector J at every continuation position, reader R); four states cat/dog/cow/horse, 8 training + 4 held-out paraphrases each; trained consequences sound + young; held-out consequence taxonomic adjective (verbalizers absent from the bus loss); loss = prototype + native + same-swap + cross-swap + persistence; three seeds × 600 AdamW steps, 4-hour wall cap, no sweeps; arms none/self/same-donor/cross-donor/ shuffled/random; kill rule and POSITIVE/CONTROLLER/FAIL status language registered before any result.

 **Lock (`d9d1513`; Codex Tier-1 review `.codex_statebus_review.md`, "not audit-ready" → fixes applied before any result):** identical recipient-conditioned history for every arm; held-out gain = donor-label fraction vs mean(shuffled, random); candidate-word-token-only summed LL with matched-baseline uplift and donor-vs-recipient DiD, raw argmax reported separately; tau = max(1e-3, Q95 of training-context same-vs-self distances); persistence loss at both decision boundaries; movement gate m1>0, m3>0, m3>=0.5·m1; LayerNorm before E and R. The earlier unreviewed run was stopped with no evaluation inspected and its outputs discarded (its smoke/train log directory `experiments/results/state_bus_v1/` was deleted in the 2026-08-29 sweep). Results: `experiments/results/state_bus_v1r1/`.

 **Pre-outcome licensed sentence (audit #28, verbatim):** `state_bus_v1r1` is a fixed three-seed training run of a 98,400-parameter supervised interface attached to frozen Qwen3-1.7B-Base. Training and held-out paraphrases are index-separated, and taxonomy verbalizers are absent from its loss. Its registered hard gates nevertheless use donor-directed relative-likelihood uplift rather than actual behavioral choice, lack a nontrivial magnitude floor, compare against off-manifold controls, and permit unsafe incomplete-seed aggregation; therefore no “persistent interchangeable state bus” claim is licensed from the registered status alone.

 **Post-outcome ceiling (audit #28):** positive → at most "descriptive evidence for a supervised semantic steering interface"; fail → closes this construction and budget only. Eval-only addendum after the run (actual choice change, magnitude floor, all-three-seeds rule, on-manifold wrong-state control, all donor pairs, per-state minimum) reported alongside the registered status. Full wordings and the state-bus never-say list:

`STATE.md` "Real-model line". Audit #28: "Finish and audit the current run once; do not scale it." Outcome and audit #29: entry above.

## interchange_v1 — operational interchangeability, Qwen3-1.7B-Base block 12, cat/dog paraphrases: closed by the locked raw-sign baseline; no swap arm (2026-08-29; ledger `interchange_v1_baseline`, `direction_r7_ruling`, `audit28`)

- **Design (Codex direction round 6; all text frozen before results).** `experiments/run_interchange.py`, `experiments/config/interchange_v1.json` (`0f252f8`); block-12 residual at a fixed anchor (` The animal`); three probe margins; native held-out probe decisions by raw margin sign, gate `>=20/24` and `>=9` per class before any donor-swap arm; context lengths 23–27 tokens (approximately, not exactly, matched — a deviation).
- **Result** (`experiments/results/interchange_v1/result.json`): cat 8/12, dog 7/12 (15/24) → BASELINE FAIL; no swap arm ran. Diagnostic only: the native signatures are strongly class-separated on all three probes relative to a calibration midpoint (24/24), but two probes carry a constant lexical bias, so raw sign confounds class with lexical frequency.
- **Ruling (direction round 7, `b9e4581`):** raw sign was the intended native-behaviour statistic; calibration-centring would change the estimand post hoc; also exact length matching missed and `cross_toward_other` divides by separation rather than its square; no corrected gate, no swap arm, artifact DEAD.
- **Licensed sentence (audit #28, verbatim):** The locked raw-zero baseline failed and closes `interchange_v1`; no swap arm ran. Calibration-relative class separation is a diagnostic design finding, not a rescue and not evidence for interchangeability. Audit #28: kill UPHELD for the locked construction only; evidence against interchangeability: NONE.
- **Never say (audit #28):** "interchangeability failed in Qwen3-1.7B-Base"; "three independent causal interventions failed". Cheapest moot-maker: a bias-controlled `interchange_v2` with calibration-midpoint/paired contrasts preregistered, on-manifold wrong-donor control, clustered reporting — authorized by direction round 8 and run (entry above; REGISTERED CONSTRUCTION-LEVEL FAIL under audit #30).

## coordinate_v3 — prediction-site two-bit coordinate (tense × number), Qwen3-1.7B-Base: gates met mechanically; audit #27 = narrow late lexical-control effect (2026-08-29; ledger `coordinate_v3_result`, `coordinate_v3_audit27`)

- **Design (Codex direction round 5).** Base model rev `ea980cb0…`; native next-token readout {is, was, are, were} at a fixed final-token prediction site; two mean residual differences estimated from 12 calibration families using only states 00/10/01 (11 never prompted); LOFO layer rule at coefficient 1; held-out 8 noun/complement families × 4 corner transports; zero arm and three seeded norm-matched random-axis-pair arms. Config `experiments/config/coordinate_v3.json` (`c8beee9`).
- **Result** (`experiments/results/coordinate_v3/baseline_result.json`, `full_result.json`): baseline 12/12 ×3; blocks 8/12/16 pass number 12/12

but tense 0/12; block 20 passes all four signed single-axis transports → frozen (|v_T| 214, |v_S| 281); corner transports 8/8, 8/8, 8/8, 8/8; zero 0/8; three random arms 0/8 each. Logit lens: W_U·(v_T+v_S) top token = ` were`; dose response is a threshold (0.25 → 0/32, 0.5 → 1/32, 1.0 → 32/32).

 **Audit #27 (`2799efb`/`d44b1de`): NEGATIVE for the coordinate artifact; positive only as a narrow lexical-control diagnostic.** Design error: every corner transport flips the number bit without changing the visible subject, so the grammar gate is 0/32 (not ~30/32) and `test_gate` was never enforced. **Licensed sentence, verbatim:** At a fixed final-token prediction site in Qwen3-1.7B-Base, a coefficient-1 block-20 patch built by adding or subtracting two mean residual differences estimated from 12 calibration families using only states 00/10/01 changed the full-vocabulary greedy next token to the predeclared member of {is, was, are, were} in all 32 held-out noun/complement-template cases, versus 0/32 for the zero arm and each of three seeded random-axis-pair arms, but the vectors project directly onto those verb logits and every corner token disagrees in number with the unchanged visible subject, so the result is a narrow late lexical-control effect rather than a grammatical, persistent, or general latent coordinate.

 **Never say (audit #27):** “A two-dimensional latent grammatical coordinate was discovered.” / “Two hidden grammatical states composed to produce an unseen state.” / “The intervention generated grammatical native continuations.” / “The state persisted through generation.” / “The result generalizes to held-out tasks, verbs, templates, models, or layers.” / “Random controls prove the learned direction is uniquely meaningful.” / “A small perturbation produced the effect.” / “Number is represented abstractly earlier than tense.” / “State 11 was unseen by the model”; only the experiment’s calibration and selection omitted it.

 **What we learned:** the cheapest explanation (late lexical readout steering living in the unembedding) is strongly supported; scoped measurement-to-artifact ratio 6.7:1 exceeded the governance threshold and was raised to the user.

## Direction rounds 5–7 (Codex direction dialogue, 2026-08-29) — rulings

 **Round 5** (`.codex_direction_r5`, not committed; no separate ledger row — the round-5 rule is recorded in ledger `coordinate_v3_result`): after the two instruct-model baseline kills, move to a base model's native next-token readout at the prediction site; a positive requires all four corner transports with zero and random controls at 0, plus one fresh audit before any claim.

 **Round 6** (`.codex_direction_r6`, not committed; no separate ledger row — design recorded in ledger `interchange_v1_baseline`): pivot from Cartesian coordinates to operational interchangeability (donor code swap between paraphrases at block 12), native-behaviour gate by raw probe sign before

calibration-scale standardization.

 **Round 7** (ledger `direction_r7_ruling`, `b9e4581`; verbatim in NOTEBOOK): `interchange_v1` dead; frozen-residual mining ruled "not working" (audit #28 reclassified this as an allocation pivot, not a scientific conclusion); central artifact becomes the co-developed latent interface `state_bus_v1`; frozen-model interventions become controls.

## coordinate_v2 — tense × grammatical number, Qwen3-1.7B: KILLED at the pre-declared baseline gate (2026-08-29; ledger `coordinate_v2_baseline`)

 **Design (Codex direction round 4; wording frozen before any result).** Qwen3-1.7B rev `70d244cc…`; states `00` present-singular, `10` past-singular, `01` present-plural, `11` past-plural; intervention = persistent-current-position (final prompt position at prefill, then the sole current position at every decoding step); baseline-first kill gate: W0 only, no `11` prompted, each of `00/10/01` must reach `>=14/16` normalized exact single-sentence outputs with `16/16` termination; on any failure the artifact is killed with no further prompt repair. Config `experiments/config/coordinate_v2.json` (`97504bf`).

 **Result** (`experiments/results/coordinate_v2/baseline_result.json`, `baseline.log`; 78 s): `00` 16/16, `10` 16/16, `01` 12/16, termination 48/48 -> `passed: false`; **artifact KILLED** by the pre-declared rule. No hidden capture, no intervention run. Misses on `01`: two items pluralized the definite object along with the subject (canonical-form ambiguity), two ignored the instruction.

 **What we learned:** the second candidate two-bit task also fails its capability baseline on the model at hand; next step is a Codex decision.

## coordinate_v1 — two-bit causal coordinate (tense × polarity), Qwen3-0.6B: UNINTERPRETABLE — INVALID POLARITY BASELINE (2026-08-29; ledger `coordinate_v1_result`)

 **Registration.** NOTEBOOK re-contextualization #27; Codex direction dialogue rounds 1–4 (`.codex_direction_r1..r4`, not committed); runner `experiments/run_coordinate.py` (`7f66f55`; matched explicit baseline / held-out single axes / fixed random directions / hash-stamped results `ddb5eee`), config `experiments/config/coordinate_v1.json`. Design: two moves `v_T`, `v_N` estimated leave-one-family-out from single-axis calibration states `00/10/01` only (state `11` never used adaptively); causal layer rule at coefficient one on the final prompt token; free decode primary; chance 1/4 among canonical forms; sham + norm-matched random controls; explicit-instruction baseline.

 **Demo outcome** (`experiments/results/coordinate_v1/demo.log`, `result.json`; Qwen3-0.6B rev `c1899de2…`, CPU): calibration hidden states captured `(16, 28, 1024)`; no block cleared the calibration rule — `acc_T = acc_N = 0.0` with termination `1.0` at every block 0–27 — so the run stopped before any held-out transport; `layer: null`.

 **Licensed headline and sentence (Codex direction round 4; verbatim):**

`UNINTERPRETABLE — INVALID POLARITY BASELINE`; "stopped at calibration" is the execution subfinding. **Coordinate-v1 is uninterpretable:** Qwen3-0.6B failed the explicit polarity capability gate, so tense × polarity was not a valid two-bit task; independently, no block cleared the coefficient-one final-prompt-token calibration rule (`0/16` for both LOFO axes at every block, termination `1.0`), so no held-out transport was run. The valid tense subtask therefore supplies a bounded negative for that exact one-shot intervention, not for residual-stream coordinates generally.

- **Diagnostics (read-only, calibration families; not results):** explicit polarity instruction fails on Qwen3-0.6B (`01` 0/8 in every wording tried); final-token and 9-token-tail patches inert at blocks 6–18, coefficients 1–3; all-position injection inert at blocks 4–12, degrading at 16/20 with one tense hit (L20 ×2). Qwen3-1.7B: tense 8/8, polarity `01` 5/8 under a repaired wording — below the gate.
- **Never say:** the model re-reads instruction tokens; no additive instruction state is present; a stable tense direction has been found.

## Round 37 — presentation-duplicated 32->16 quotient world: NO ARCHITECTURAL WIN; last toy-world round (2026-08-29; ledger `round37_lock`, `round37_result`, `round37_audit`)

- **Lock** (`round37_lock`, `eb61470`; config sha256 `5a419bea…`, module sha256 `6786b67b…`; registered by Codex in `theory/EXPERIMENTS.md`): 32 presentations, true 16-class quotient; quotient-factored `z=(q,p)` carrier vs unrestricted carrier × 2 presentation roles × 5 seeds; rolled interchangeability primary; non-gating horizon/role diagnostics; Tier-1 review passed (fixture 46.3 s, 529.5 MiB peak). Runner/config retired from the active path after the result (`f6dac0e`; git history).
- **Result** (`round37_result`, `b5bef1b`; artifacts `experiments/results/presentation_quotient_v1_{factored,unrestricted}/` `verdict.json` + `manifest.json` + `config.json`; evidence/weights retired, sha256-pinned; 35 min CPU wall): both carriers `FAIL — BEHAVIOR UNDERFIT OR BASE SIGNATURE UNSUPPORTED`; comparison `NO ARCHITECTURAL WIN`; both verdict files carry one factored-primary world verdict. Diagnostic-only: H2 held-out supported-truthful cells factored 867–1184/1184 vs unrestricted 795–1184/1184; H3 factored 365–754/1056 vs unrestricted 485–992/1056; first divergence predominantly at step 3 of H3.
- **Licensed sentence (Round 37 audit, `round37_audit`, `d9ca753`; verbatim):** Under the frozen exact toy reducer, neither carrier reached behavior-qualified held-out presentation transfer or rolled interchangeability; descriptively the unrestricted carrier had higher transfer and interchangeability rates in 9 of 10 paired seed × role units, while failures were predominantly—but not exclusively—future-signature failures and H3 first divergence was predominantly at step 3, so the imposed factorization showed no benefit in this setup.
- **Never say:** every failure was future-signature / terminal responses never failed (128 factored and 69 unrestricted failure cells involve a

terminal error; four cells are terminal-only) / the factorization
constraint is harmful / unrestricted is the architectural winner / the
Round 36d mechanism reproduced (only the horizon localization recurred) /
the hole is a property of behaviour-supervised learning (hypothesis only) /
anything about real residual streams based on Round 37.

 **What we learned:** the toy program ends; transferable residue = identity
by causal interchangeability, and never use exact certificates as primary
evidence for learned continuous systems.

## Rounds 36 v1 / 36b / 36c / 36d — minimal operational-quotient world (closed; audits #23–#26 govern)

 **Round 36 v1 — valid registered FAIL** of its frozen `0.10/0.90` exact
reducer, every gate (`073037f`; adjudicated `e69ac72`; config
`experiments/config/operational_quotient_v1.json` (retired; git history); artifacts
`experiments/results/operational_quotient_v1/`). Only licensed
reading = audit #23, verbatim in `STATE.md`: a behavior-, calibration-, and
exactness-confounded non-certification of the registered operational
quotient — not evidence of no approximate composable structure; the
confidence-free replay numbers are DIAGNOSTIC only. Never say "did not
supply ... composable action algebra", "0/176 cross-seed agreement" as a
cell count, or "FIT BUT NON-CONGRUENT" for a support-only failure.

 **Round 36b — complete; all four cells behaviour-ineligible** (lock V3,
review #2 RUN-READY, `61e2430`; results `abef6cf`; ledger
`round36b_ladder`; audit #24 `round36b_audit24`, adopted `57b0961`;
configs `experiments/config/operational_quotient_36b_{S16,S64,LR64,W64}.json` (retired; git history);
artifacts `experiments/results/operational_quotient_36b_*/`).
Every cell `FAIL — BEHAVIOR UNDERFIT; QUOTIENT INELIGIBLE`; no eligible
cell, no PASS. Only licensed reading = audit #24, verbatim in `STATE.md`:
the ladder did not reach exact held-out eligibility, while the
reachability of that exact learned precondition remains unvalidated — not
proven unsatisfiable; W64's cross-seed-stable canonical one-step skeleton
is informational only, not a certified operational quotient/action
algebra. Never say "unsatisfiable by construction", "the exact structural
gates are unreachable", "the latent is unorganized", or "organized"
without the local/canonical scope.

 **Round 36c — complete; both cells FAIL (POSITIVE-CONTROL scope; audit
#25 governs).** Explicitly transition-supervised learned positive control
(behavioural BCE + `1.0 *` MSE to the stop-gradient true-successor
encoding; unchanged exact reducer; lock V2, review #2 RUN-READY,
`dd699e2`; configs `experiments/config/operational_quotient_36c_{w32,w64}.json`, retired; git history).
w32 (`3742df8`; ledger `round36c_w32_positive_control`): FAIL on every
exact gate in every seed, action-table truth 0/5, cross-seed table FAIL.
w64 (`d5975c1`; ledger `round36c_w64_positive_control`): FAIL — swap/toggle
table 4/5, held-out depth-2 closure 3/5, all other gates 0/5. Only licensed
reading = audit #25 (`round36c_audit25`, adopted `0f61280`; verbatim in

`STATE.md`) and the w32 adjudication's licensed sentence (`round36c_w32_adjudication`): the registered joint moving-target learned-target recipe did not reach the certificate; learned gate reachability unresolved — not proof that the carrier or exact gates are unreachable; no behaviour-only interpretation; W64 stays informational under audit #24; only the oracle fixture has passed the reducer. Never say "not reachable even with direct supervision", "certification-regime problem" as the cause, "the auxiliary objective caused it" (leading hypothesis only), or "W64 beat the control". No further moving-target cells.

 **Round 36d — complete; joint FAIL — INTERCHANGEABILITY (POSITIVE-CONTROL, frozen chart; audit #26 governs).** The one permitted frozen-target head-only calibration (audit #25 rank 1): hash-pinned behaviour-only W64 encoder/readout frozen, fresh width-64 transition head trained on the stationary 176-cell successor table for 16,000 steps, BCE as an evaluation gate, unchanged exact reducer; ONE capped cell. Registered before any outcome (ledger `round36d_37_registered` -> `round36d_impl_discrepancy` -> lock V2 `round36d_lock_v2` -> review #1 RUN-READY `round36d_run_ready`; runner + config `6a95c29`, `experiments/config/operational_quotient_36d_w64.json`, retired; git history). Run `7a5ce35` (ledger `round36d_frozen_chart_positive_control_produce` / `_reduce`, `round36d_frozen_chart_control`; `118.454 s` of a `480 s` wall; artifacts `experiments/results/operational_quotient_36d_w64/` — `config.json`, `manifest.json`, `verdict.json` committed; `evidence.json`, `weights.npz` git-ignored, sha256-pinned): exact behaviour in all five seeds (`21,184/21,184` train, `2,240/2,240` held out); exact PASS on quotient availability, well-definedness, toggle involution, swap/toggle table, H2 closure, H3 closure, canonical action-table truth, and the cross-seed table; interchangeability misses `16/5/28/98/0` of `132,160` cells (`147/660,800`; all depth-2 rolled histories followed by H3; 89 confidence-only, 58 with a future-probe truth error; no immediate endpoint error), so `1/5` seeds pass and the joint status is `FAIL — INTERCHANGEABILITY`. Only licensed reading = audit #26 (`round36d_audit26`, adopted `cad85ef`; verbatim in `STATE.md`): narrow individual-gate reachability under privileged full-table supervision, not quotient discovery or a complete learned certificate; no complete learned artifact has passed the joint reducer (only the oracle fixture has); the adequacy ratio is diagnostic and does not identify cause. Never say "reached the exact certificate", "the learned-pass gap is closed", "the quotient/action algebra was learned", "eight independent gates", or "interchangeability generally fails". Round 36 calibration is closed; no further Round 36 cells.

## NLM-007 — LM residual-stream dynamics; middle-depth ridge lead withdrawn under the identity baseline; displacement ladder adjudicated (audit #8 wording); forward-time move adjudicated NOT MET = nonpass, not a kill (Round 20, audit #9); within-style null =

**diagnostic only (both arms); LOCO A/B within-family positive, bounded (audit #10 wording; adjudicated Round 22); equalized addendum defect-affected, descriptive only (audit #11); unseen-word runs A/B mechanical pass, formal gate pending (Round 23, audit #12); corrected equalized reruns contract-correct (A adjudicated Round 25; B pending); residualization A-static contract-valid, adjudicated Round 26 as corrected by audit #14 (registered-presentation sensitivity + surviving X-linked residual predictability; neither state nor presentation-independence); A-augmented (`P_aug-score4`) adjudicated Round 27 as corrected by audit #15 (nested sensitivity on the same sentinel-A cells, not a replication; outcome-clean but transductive within carrier); B-static adjudicated Round 28 as corrected by audit #16 (F4–F20 pass, F0 fails; a correlated two-sentinel check, not replication); B-augmented (`P_aug-score4`) scored on the third launch after two losses in the F8 grammar block, adjudicated Round 32 as amended-implementation and SVD-telemetry-incomplete (F4–F20 pass, F0 fails); the sentinel {A,B} × {P_static, P_aug-score4} table is complete only for the residual-versus-four-word-only-null mechanical gate — within-decoder, within-population condition robustness, not replication (audit #17); patched A-static `resSA2` complete and ADJUDICATED (Evidence gate 2026-08-28, PASS qualified: the four-cell table is complete on one common K=13/four-null/crossed-bootstrap scale; F4–F20 pass in all four correlated cells; F0 non-qualifying in three cells with a weak pooled A-score4 exception; audit #18: F0 is a model-class-sensitive diagnostic, not an all-field dead end); contextual-prefix screens `ctxscr_A/B` = point-only screens that did not triage the X-conditioned hypothesis out at F4–F20 (ctx effective df ~42.7 vs state ridge ~210–406; no state-reading gate passed; audit #18); SVD telemetry gate PARKED and unpassed by allocation (repair cap = global CLAUDE.md §2.7, not an AGENTS.md rule); Round 33 consequence instrument implemented, UNRUN, PARKED and unpassed after Tier-1 re-review #4 NOT-READY (joint-key rule closed; provenance/parity blockers open; repair cap applied as an allocation decision, ledger `nlm007_consequence_instrument_parked`; branch `conseq-instrument`, main analyzer at HEAD); contextual-prefix completions `ctx_A/ctx_B` (unresidualized) COMPLETE, scored pending adjudication, audit #19 wording upheld by audit #20: descriptive higher-EDF predictor comparisons — at F4–F20 the higher-EDF state predictor retained a positive held-out score difference from the registered `token_ids_v1` context-only pair with positive crossed lower bounds, 8/8 point-positive keys, no family collapse, support 1.0; state ridge ~5–10× the contextual ridge's effective df; F0 non-qualifying; NOT evidence that context failed, that capacity is the sole confound, or that operational state is identified (the phrase "did not close the gap" is withdrawn); Round 34 capacity-matched audit registered (`d493cf2`) and implemented (`9eb1301`; producer RUN-READY, joint reducer flagged) but HELD pending the preregistered Round 34a matched-EDF core screen (`f97a533`; K=13 KL-rank diagnostic, raw continuous KL confirmatory; audit #19 staging); `ctxS_A` and `ctxS_B` (P_static-residualized) COMPLETE, scored pending adjudication, audit #20 wording (sentinel B mirrors A: context cosine ~0.04–0.08 / nerr ~1.00 vs residual ridge cosine ~0.52–0.58 / nerr 0.82–0.86): the registered token-context ridge/kernel falls to held-out cosine ~0.04–0.07 and normalized error ~1.00 while the residual `X_perp` ridge keeps cosine ~0.56–0.62 and normalized error 0.78–0.83; raw context performance is highly non-robust to the registered `P_static` residualization and therefore `P_static`-aligned in this fitted design — NEVER "beyond template metadata", "presentation removed", "largely by construction", or "same feature space"; licensed positive wording: a higher-capacity predictor from `X_perp` carries held-out predictive information beyond the registered `P_static` nuisance projection and this fixed `token_ids_v1` context field; Round 34a matched-EDF core screen RUN-READY (`6b93ff1`, four Tier-1 rounds; six runs queued: `ctxcapA_raw`, `ctxcapB_raw`, `ctxcap_raw_joint`, `ctxcapA_static`, `ctxcapB_static`, `ctxcap_static_joint`; both estimands required, no cross-estimand verdict); Round 34b (P/C partial-overlap screen) and Round 34c (item-embedding-by-P_static X-free comparator) preregistered (`3b49321`, `ff69d82`),**

**implemented on the main analyzer, UNRUN and under Tier-1 repair (review #1 NOT-READY on four items), to run after Round 34a and before the full Round 34 (held); Round 35 typed truth-evaluable world preregistered docs-only (`c74bfab`; authors nothing until the 34a/34b/34c ladder resolves); Round 33 parked; chain running on the frozen analyzer copy (`6b93ff1` blob): parity check (`parity_head` A/B done, `parity_ref` A running, then B and a parity verdict), then the six Round 34a runs; capture extension committed (`4137258`); contextual-prefix X-free baseline committed (`eab0a68`); populations: v1 design-void (audit #16), v2 and v3 voided by the independent linguistic adversary, v4 approved 48/48 and frozen — a bounded mentioned-string instruction micro-world (audit #17); operation-verb update = declared-operation-verb context intervention; Round 31 chain and X-free chain disarmed; Freedman–Lane conditional on one A-static cell; audit #17 allocation ruling in force (Round 33); retention marker non-commensurate (audit #13); **PROGRAM CONTINUATION RULING (2026-08-29, ledger `nlm007_program_continuation_ruling`; supersedes every queue item before it in this header): NLM-007 STOPPED as an open-ended program (infrastructure drift 6:1); terminal closeout ladder only — Round 34a raw (DONE, CONTINUE) -> Round 34a static (RUNNING) -> Round 34b (conditional on both 34a CONTINUE + final bounded repair RUN-READY) -> Round 34c (conditional on a 34b CONTINUE); first STOP/MOOT/REDUNDANT/INCONCLUSIVE rung ends it; all-CONTINUE = one narrow measurement claim then closure; CUT: full Round 34, Round 33 (branch archived as tag `archive/conseq-instrument-parked`), the parity check as a gate, the random-weight null, a second decoder; parity verdict IDENTICAL A/B (`analysis_parity_*.json`; evidence only); Round 34a RAW CONTINUE at F4–F20 in both sentinels with capacity-matched cosine margins +0.04 to +0.08 (LBs 0.02–0.05), 8/8 keys, F0 INCONCLUSIVE/diagnostic, joint COMPLETE/SCREEN-ONLY CONTINUE — capacity matching removed most of the unmatched raw gap; a narrow survival, not a strong one, not a state claim; Round 35 = requirements envelope only; Round 36 minimal operational-quotient world = the constructive program (design registered `c26eee4`; implementation in progress); producer/reducer separation mandatory** (2026-08-29); **CLOSED 2026-08-29 at the Round 34b INCONCLUSIVE rung — see the program status above and the 34a-static / 34b bullets below**

- **Lock.** Round 13, documentation-only (ledger `nlm007_round13_lock`; design `theory/dialogue/003.md`, `theory/EXPERIMENTS.md`); Round 14 amendment `097e2df`; Round 16 correction (completed law read at the substituted slot; final pair uses `head(Yhat)` on the post-norm state, ledger `nlm007_round16_corrected_rerun_predeclared`). Qwen3-0.6B (28 layers), 80 one-token words × 16 carriers, four carrier-block folds; six layer pairs; law ladder word-mean / kNN / ridge / low-rank affine / kernel ridge; per-carrier oracle; within-word carrier permutations; two-way cluster bootstrap. Decision: ≥0.05 lead over the best static chart with lower bound >0 on successor cosine and both completed-law readouts in ≥2 layer pairs. CPU only.
- **Capture.** `experiments/run_lm_dynamics.py` → `experiments/results/lm_dyn_v1/manifest.json` (model revision c1899de2…, batch 16, batched-vs-single nulls ≤ 6.1e-5, 79 s). `states.npz` is git-ignored; sha256 `6ec9520845811bbd…` recorded in the manifest.
- **Artifacts (`experiments/results/lm_dyn_v1/`; all kept).**

- `analysis.json` — fallback run, pairs L0→1 / L8→9 / L27→28, 20 shuffles, 500 boot (ledger `nlm007_fallback_declared`, `nlm007_v1_fallback`; 1427 s, 19% over the 20-min cap). Successor-endpoint numbers valid; completed-law

numbers read at the last token — **secondary only, invalid for the lock** (Tier-3 audit #5).
- `analysis_ext.json` — extension, pairs L4→5 / L12→13 / L20→21 (ledger `nlm007_ext_predeclared`, `nlm007_ext_v1`; 1100 s). Same validity split: successor valid, completed-law secondary/invalid for the lock.
- `analysis_slot.json` — **canonical slot-endpoint result**: corrected rerun over all six pairs, 20 shuffles, 500 boot, seed 13007 (ledger `nlm007_slot_v1`; 2145 s of a 3300 s budget; reload check unchanged). Exploratory at the reduced 20/500 budget; its L8/L12 qualification is withdrawn below.
- `analysis_basesmoke.json` — moot-maker smoke at L8→L9 only, 2 shuffles / 20 boot, point estimates (ledger `nlm007_baselines_smoke_L8`; 796 s). Pipeline validation; superseded by `analysis_base.json`.
- `analysis_base.json` — predeclared six-pair moot-maker run (identity-plus-residual and per-carrier affine; ledger `nlm007_baselines_v1`). Took 4540.8 s against the predeclared 3300 s budget: **budget-incomplete exploratory artifact** — measured values retained, no planned full-budget gate earned; the null-making withdrawal still applies (Round 18, audit #7).
- `identity_check.json` — stored-true-successor identity test of the slot completion at every pair and carrier (ledger `nlm007_identity_check_v1`; audit #6 action 3). **Valid**: routing validated to measured precision (per-pair max KL 1.9e-6 to 6.2e-6 over 16 × 80 cells); no per-carrier error profile or fresh-float32 comparison was stored.
- `analysis_deltasmoke.json` — `--target delta` pipeline smoke at L8→L9 (1 shuffle / 10 boot; ledger `nlm007_delta_smoke_L8`). **Not a result.**
- `analysis_delta.json` — **valid, adjudicated (Round 19, audit #8)**: five-pair displacement ladder (ledger `nlm007_delta_predeclared`, `nlm007_delta_v1`; 1750.3 s of the 5700 s wall; support 1.0). Reading below.
- `forward_manifest_A.json` / `forward_manifest_B.json` — forward-time captures, sentinel A = '.' and B = ',' (ledger `nlm007_forward_predeclared`, `nlm007_forward_locality_control`); `forward_states_A/B.npz` git-ignored. Locality control passes under the Round 20 corrected clause (ledger `nlm007_forward_locality_ruling`); A/B unappended q-states and laws identical bit-exactly (ledger `nlm007_forward_AB_equality`).
- `analysis_fwdsmoke.json` — `--source forward` pipeline smoke at F8, A (1 shuffle / 10 boot; ledger `nlm007_forward_smoke_F8A`). **Not a result.**
- `analysis_fwdA.json` — forward-time move, sentinel A = '.', layers 0/4/8/12/20, 20 shuffles / 500 boot (ledger `nlm007_forward_fwdA`; 2220 s). **Valid; adjudicated Round 20 + audit #9**: the primary arm did not meet the preregistered two-layer same-sentinel criterion (only `F20` qualifies) — a nonpass under the historical contract, not a kill.

Oracle field meaningless (ledger `nlm007_oracle_defect_forward`).
- `analysis_fwdB.json` — sentinel B = ',' arm (registered as the control/replication arm; a correlated same-population check), same settings (ledger `nlm007_forward_fwdB`; 1823 s). **Valid; adjudicated Round 20**: `F12` and `F20` qualify (ridge); cannot rescue the period arm. Oracle field meaningless. Reading below.
- `analysis_stylesmoke.json` — `--style-null` + KL-rank pipeline smoke at F8, A (2 shuffles / 10 boot; ledger `nlm007_stylenull_smoke_F8A`). **Not a result.**
- `analysis_styleA.json` — within-style-family target null, sentinel A, layers 0/4/8/12/20, 20 shuffles / 500 boot (ledger `nlm007_stylenull_predeclared`, `nlm007_stylenull_styleA`; 2213 s; support 1.0). **Diagnostic only (audit #9)**: the null is an alignment-destruction diagnostic, not a clean style null; its KL-rank endpoint ranked K = 7 candidates instead of the preregistered 10 — labelled, **not contract-valid on that endpoint**. No claim. Oracle field meaningless.
- `analysis_styleB.json` — sentinel B arm of the same control (ledger `nlm007_stylenull_styleB`; 2238 s; support 1.0): `F8/F12/F20` pass the historical style gate mechanically, `F4` misses, `F0` fails. **Diagnostic only**, same K = 7 label, no claim (Round 21). Oracle field meaningless.
- `analysis_locoA.json` — within-family leave-one-carrier-out control, sentinel A, layers 0/4/8/12/20, 500 word-clustered boot (ledger `nlm007_loco_predeclared`, `nlm007_loco_locoA`; 2902 s of the 4500 s wall; support 1.0). **Scored under the Round 21 rule; adjudicated Round 22.** Reading below (audit #10 wording). Oracle field meaningless. The LOCO smoke (`nlm007_loco_smoke_F8A`) crashed before writing a JSON; log numbers only.
- `analysis_locoB.json` — sentinel B arm of the LOCO control (ledger `nlm007_loco_locoB`; 3091 s; support 1.0). **Scored; adjudicated Round 22** (audit #11 precision). Reading below. Oracle field meaningless.
- `analysis_locoeqA.json` — Round 22 equalized-baseline LOCO addendum, sentinel A (word-only one-hot ridge; shrunk word mean; ledger `nlm007_loco_addendum_predeclared`, `nlm007_loco_locoeqA`; 2911 s; support 1.0). **Defect-affected (audit #11; ledger `nlm007_locoeq_defect_inner_centre`): outer margins descriptive only**, inner-selection claim invalid. The equalized smoke (`nlm007_locoeq_smoke_F8A`) artifact was deleted; log numbers only.
- `analysis_locoeqB.json` — sentinel B arm of the addendum (ledger `nlm007_loco_locoeqB`; 2977 s; support 1.0). **Defect-affected (audit #11): descriptive only**; `F12/F20` mechanical, `F4/F8` miss on skill/KL-rank lower bounds, `F0` fails.
- `analysis_unseenA.json` / `analysis_unseenB.json` — Round 22 unseen-word runs, sentinel A = '.' (ledger `nlm007_unseen_unseenA`; 2239 s) and B = ',' (ledger `nlm007_unseen_unseenB`; 2256 s; predeclared

`nlm007_unseen_predeclared`); support 1.0, eight block × word-fold keys. **Mechanical pass at `F4/F8/F12/F20`, `F0` fails; formal gate pending (audit #12)** — status "mechanical pass under the recorded reduction; formal gate pending a contract-correct bootstrap". Reading below.

- `analysis_locoeq2A.json` — corrected equalized addendum, sentinel A (analyzer `d10fc66`: inner two-carrier centre; comparator frozen by calibration score; ledger `nlm007_loco_locoeq2A`; 3753 s of the 4500 s wall; support 1.0). **Contract-correct; adjudicated Round 25** (audit #13 wording). Reading below.
- `analysis_locoeq2B.json` — sentinel B arm of the corrected addendum (ledger `nlm007_loco_locoeq2B`; 4196 s; support 1.0). **Contract-correct; Codex adjudication pending** (required before any combined A/B equalized reading). Reading below.
- `analysis_residsmoke.json` — smoke of the audit #12 bootstrap repair, the stronger unseen-word lexical nulls, `--residualize static`, and the Round 24 raw four-null shadow arm (sentinel A, F8, 1 shuffle / 10 boot; ledger `nlm007_resid_smoke_F8A`, `nlm007_resid_shadow_smoke_F8A`; design `nlm007_residualization_predeclared`). **Not a result**; meets the Round 25 raw-shadow launch prerequisite at pipeline level.
- `analysis_resSA.json` — residualization, sentinel A, `P_static` (Round 25 launch ruling, ledger `nlm007_residualization_budget_amended`: 120-minute wall, K = 13, five layers, two unseen-word folds, 20 shuffles / 500 boot; ledger `nlm007_resid_resSA`; 4405.7 s; support 1.0). **Contract-valid for the primary residual-vs-null question; scored and adjudicated Round 26 as corrected by audit #14** (ledger `nlm007_audit14_adopted`). Pre-patch analyzer: retention reported only as "the predeclared robustness marker is mechanically met" (ledger `nlm007_retention_marker_defect`, `nlm007_retention_common_scale_predeclared`). Reading below.
- `analysis_resAA.json` — A-augmented (`P_aug-score4`: `P_static` plus at most four scores obtained by projecting a leave-calibration-word-pool carrier mean of `X` into a basis learned from calibration carriers; the full carrier-mean vector is not appended — audit #15), same contract, common-scale retention field present (ledger `nlm007_resid_resAA`; 4737.8 s of the 7200 s wall; support 1.0; adjudicated `nlm007_resid_resAA_adjudicated`, Round 27, as corrected by audit #15). **Outcome-clean but transductive within carrier; not unqualifiedly contract-valid** until the pre-result meaning of the lock's carrier-mean clause is resolved. Reading below.
- `analysis_resSB.json` — B-static (`P_static`, sentinel ','), same contract, common-scale field present (ledger `nlm007_resid_resSB`; 4598.4 s; support 1.0). **Contract-valid; adjudicated Round 28.** Reading below.
- `analysis_resAB.json` — B-augmented (`P_aug-score4`, sentinel ','), same contract, common-scale field present (ledger `nlm007_resid_resAB`;

5073.8 s of the 7200 s wall; support 1.0). Third launch: the first two launches were lost in the F8 grammar block (ledger `nlm007_resid_resAB_crash`, `nlm007_resid_resAB_crash2`; erratum `nlm007_erratum_resAB_crash_localization`: the first loss occurred while entering grammar_w0 with no traceback, only the second is localized to torch `linalg.svd` non-convergence on the fitted low-rank coefficient matrix at grammar_w1 — "the F8 grammar block", not "the same fold"); the third ran with a numpy float64 LAPACK SVD fallback. **Adjudicated Round 32 (`f8a2c48`, ledger `nlm007_round32_labels`) with the labels amended-implementation and SVD-telemetry-incomplete**: F4–F20 pass the residual-vs-null gate, F0 fails; ridge-only cosine and skill margins are mechanically reportable, the K = 13 KL-rank endpoint and every low-rank interpretation are amendment-qualified until the SVD telemetry gate (per-fit provider/exception/shape/finite/spectrum/rank telemetry plus a float64 NumPy shadow-backend agreement check) passes Tier-1 numerical review. Reading below.

- `analysis_resSA2.json` — patched A-static rerun (identical design to `resSA`, common-scale retention block; ledger `nlm007_resid_resSA2_predeclared`, result `nlm007_resid_resSA2`). **Complete (5825 s, committed analyzer): F4, F8, F12, F20 pass the residual-vs-strongest-null gate (block-first LBs cos >= 0.46, skill >= 0.18, KL-rank >= 0.20; 7-8/8 keys; retention held on all three endpoints); F0 fails (2/8 full-gate keys, negative skill/KL-rank margins).** This fills the {A,B} x {P_static, P_aug-score4} table on one common scale. **Adjudicated (Evidence gate 2026-08-28, ledger `nlm007_fourcell_adjudication`; PASS, qualified):** strict full-gate keys 7/8, 7/8, 6/8, 8/8 (the "7-8/8 keys" above are jointly positive keys); minimum crossed block-first lower bounds cos 0.458, skill 0.175, K=13 KL-rank 0.197; all 48 F4–F20 layer × endpoint common-scale ratio medians exceed 0.5 (estimator/null competition ratios, not retained signal). Licensed wording is the audit #17 sentence in STATE.md (condition robustness within one decoder and population, not replication, state, or a native law). Provenance erratum: ledger row `nlm007_resid_resSA2` says sentinel `2`; the artifact records `sentinel_tag: A` (`nlm007_erratum_resSA2_sentinel_label`).
- `analysis_ctxscr_A.json`, `analysis_ctxscr_B.json` — contextual-prefix X-free **point-only screens** (`--ctx-screen`, `token_ids_v1`, committed analyzer copy; ledger `nlm007_ctxprefix_ctxscr_A`, `nlm007_ctxprefix_ctxscr_B`). Not gate adjudications. Audit #18 wording: at F4–F20 the cell-state ridge exceeds the strongest `token_ids_v1` field by approximately 0.11–0.20 cosine and 0.11–0.20 normalized-error reduction in both sentinels, so the screen did not triage the X-conditioned hypothesis out; it does not establish that the state-reading gate is live (skill, continuous-KL, crossed intervals, joint key count, collapse checks, and a capacity-matched comparison are

unscored). Contextual ridge effective df ~42.7 vs state ridge ~210–406 across F4–F20. At F0 the contextual field nearly closes ridge direction (cosine gaps ~0.019/0.018) but not magnitude (normalized error ~1.00 vs 0.97) — not proof that "prefix IDs explain F0".
- `analysis_ctx_A.json` (ledger `nlm007_ctxprefix_ctx_A`; 5783 s) and `analysis_ctx_B.json` (`nlm007_ctxprefix_ctx_B`; 4476 s) — unresidualized contextual-prefix completions (`--contextual-prefix-xfree`, 20 shuffles / 500 boot; committed-analyzer copy): **complete, scored pending adjudication; audit #19 wording governs.** Each is a completed unresidualized, outer-held-out predictor comparison. At F4–F20 the higher-EDF cell-state ridge retained a positive held-out score difference from the registered `token_ids_v1` context-only pair on displacement cosine, normalized error, frozen completion skill and continuous KL — A: cosine +0.15 to +0.20 (LB ≥ 0.13), normalized error +0.14 to +0.20, skill +0.34 to +0.46 (LB ≥ 0.25), continuous KL +0.27 to +0.45 (LB ≥ 0.17); B: cosine +0.11 to +0.18 (LB ≥ 0.09), normalized error +0.11 to +0.16, skill +0.33 to +0.41, continuous KL +0.24 to +0.40 — with positive crossed lower bounds, all eight outer keys point-positive, no carrier family collapse, support 1.0. F0: cosine +0.019 (A) / +0.018 (B) while skill and continuous-KL lower bounds cross zero and the continuation family collapses — non-qualifying, model-class-sensitive. The state ridge has approximately 5–10 times the selected contextual ridge's effective degrees of freedom and a different feature class; inner tuning is calibration-only (no held-out-outcome double use); the endpoints are correlated functionals of one prediction. Licensed reading: a higher-EDF state predictor has a positive held-out score difference from this fixed context-only pair — a descriptive predictor comparison, not evidence that context failed, capacity is the sole confound, or operational state has been identified. Never "did not close the gap"; never "gate live". Audit #20 upholds this reading for `ctx_B`.
- `analysis_ctxS_A.json` (ledger `nlm007_ctxprefix_ctxS_A`; 5655 s; `--residualize static`, 20 shuffles / 500 boot; committed-analyzer copy) — **complete, scored pending adjudication; audit #20 wording governs.** The corresponding sentinel-A comparison on the `P_static`-residualized relation. At F4–F20, the registered token-context ridge/kernel falls to held-out cosine approximately 0.04–0.07 and normalized error approximately 1.00, while the residual `X_perp` ridge has cosine approximately 0.56–0.62 and normalized error 0.78–0.83; the crossed cosine, normalized-error, skill, and continuous-KL margins are positive (cosine +0.51 to +0.58, LB ≥ 0.46; normalized error +0.17 to +0.23; skill +0.32 to +0.49; continuous KL +0.26 to +0.48; 8/8 keys), with support 1.0 and no family collapse. The contextual ridge is already at approximately 47 EDF in every F4–F20 key and the contextual kernel is approximately 48 EDF at F8–F20, so the collapse is not a low-selected-EDF artefact. F0: cosine margin positive, normalized-error,

skill, and continuous-KL margins negative — model-class-sensitive diagnostic. `P_static` is a ten-column block/length/position nuisance design; `token_ids_v1` is a distinct approximately 205–222-column carrier/POS token-context design (at most 48 distinct training rows, omitting the item token and cell `X`); only `X` and `Delta` are residualized. Licensed reading: the registered context field's raw predictive signal is highly non-robust to `P_static` residualization and is therefore `P_static`-aligned within this fitted design; a higher-capacity predictor from `X_perp` carries held-out predictive information beyond the registered `P_static` nuisance projection and this fixed `token_ids_v1` context field. Never "largely by construction", "beyond template metadata", "presentation removed", "same feature space", a quantified presentation share, mediation, or causal attribution; not an identified state contribution, native law, or representation-level hostile hole.

- `analysis_ctxS_B.json` (ledger `nlm007_ctxprefix_ctxS_B`; 4784 s; `--residualize static`, 20 shuffles / 500 boot; committed-analyzer copy) — **complete, scored pending adjudication; the same audit #20 wording governs.** Sentinel B mirrors sentinel A: at F4–F20 the registered `token_ids_v1` ridge/kernel falls to held-out cosine approximately 0.04–0.08 and normalized error approximately 1.00, while the residual `X_perp` ridge keeps cosine approximately 0.52–0.58 and normalized error 0.82–0.86; residual ridge minus the strongest contextual arm: cosine +0.46 to +0.51 (LB ≥ 0.42), normalized error +0.14 to +0.19, skill +0.34 to +0.45, continuous KL +0.24 to +0.41; 8/8 keys, support 1.0, no family collapse. F0: cosine margin positive, normalized-error, skill, and continuous-KL margins negative. Licensed reading (audit #20): raw context performance is highly non-robust to the registered `P_static` residualization and therefore `P_static`-aligned in this fitted design; not identified as presentation; not by construction; not a state contribution; the residual predictor separation is descriptive and unmatched in capacity. Same never-say list as `ctxS_A`.
- **Program continuation ruling (2026-08-29; ledger `nlm007_program_continuation_ruling`, commit `6e74798`; supersedes the queue described in the bullets below):** NLM-007 is STOPPED as an open-ended program (infrastructure drift 6:1 by the constitution's tripwire) and closes via one terminal ladder — 34a raw (once) -> 34a static (once, separately; no cross-estimand pooling) -> 34b (only if both 34a estimands CONTINUE and its final bounded repair is RUN-READY without scope expansion) -> 34c (only after a 34b CONTINUE). First STOP/MOOT/REDUNDANT or INCONCLUSIVE rung ends the ladder; all-CONTINUE records "the predictor separation survived these registered controls" and NLM-007 closes anyway. CUT: full six-arm Round 34; the Round 33 consequence instrument (branch `conseq-instrument` archived as tag `archive/conseq-instrument-parked`, never run); the parity check as a

gate; the random-weight architecture null; a second decoder. Round 35 is a requirements envelope only. Governance: mandatory producer/reducer separation.

- `analysis_parity_head_A/B.json`, `analysis_parity_ref_A/B.json` — HEAD-vs-refactor CPU parity check (ledger `nlm007_parity_verdict`, commit `cbed1ee`; contextual-prefix static screens on the committed analyzer copy vs the parked branch's refactored analyzer; decision JSON scrubbed of timing/SVD/shadow fields): **IDENTICAL for A and B.** The gate is cut by the continuation ruling; kept as evidence only.
- `analysis_ctxcapA_raw.json` / `analysis_ctxcapB_raw.json` / `analysis_ctxcap_raw_joint.json` (+ hash-bound sidecars `round34a_evidence_ctxcapA_raw.npz` / `round34a_evidence_ctxcapB_raw.npz`; frozen analyzer copy `analyze_r34a_frozen.py` = blob `6b93ff1`; 291 s / 254 s, tokenizer only; ledger `nlm007_round34a_raw`, commit `60d06f7`) — **Round 34a RAW: CONTINUE at F4–F20 in both sentinels.** Strongest matched margin per layer (F4/F8/F12/F20): A cosine +0.072/+0.057/+0.045/+0.042 (crossed LBs 0.034/0.024/0.019/0.024), normalized error +0.073/+0.047/+0.040/+0.054; B cosine +0.082/+0.064/+0.047/+0.043 (LBs 0.049/0.034/0.023/0.022), nerr +0.088/+0.054/+0.042/+0.067; 8/8 keys jointly positive at every F4–F20 layer; strongest contextual arm = the token-id kernel at most layers; F0 INCONCLUSIVE (matched EDF undefined; diagnostic only). Joint: COMPLETE/SCREEN-ONLY, CONTINUE, common layers F4/F8/F12/F20 (one reducer NaN-replay defect fixed on the main analyzer, producer untouched; ledger `nlm007_round34a_reducer_nan_fix`). Reading: capacity matching removed most of the unmatched raw gap (`ctx_A`/`ctx_B` cosine margins +0.11 to +0.20); a +0.04 to +0.08 separation survives (audit #21 withdrew "lower bounds just above the 0.02 threshold": the registered rule is point margin >= 0.02 with LB > 0; smallest raw point 0.0397, smallest LB 0.0146) — a small-magnitude but systematic within-design survival, not a state claim.
- `analysis_ctxcapA_static.json` / `analysis_ctxcapB_static.json` / `analysis_ctxcap_static_joint.json` (+ `round34a_evidence_*_static.npz`) — **Round 34a STATIC: CONTINUE at F4–F20 in both sentinels** (ledger `nlm007_round34a_static`, commit `850414c`; 314 s / 304 s; joint re-run on the main analyzer after the NaN-replay reducer fix: COMPLETE/SCREEN-ONLY, CONTINUE, common layers F4/F8/F12/F20). Strongest matched margins (F4/F8/F12/F20): A cosine +0.306/+0.383/+0.373/+0.435 (LBs 0.227/0.315/0.305/0.353), nerr +0.047/+0.089/+0.084/+0.115; B cosine +0.329/+0.352/+0.337/+0.367 (LBs 0.262/0.278/0.275/0.264), nerr +0.065/+0.082/+0.077/+0.100; 8/8 keys; F0 INCONCLUSIVE (diagnostic). Selected state ridge 202–384 EDF; contextual ridge target ~47; kernel target ~48 at F8–F20 but ~4.36 in 4/8 A and 2/8 B F4 keys. Licensed wording (audit #21): the residual predictor separation was not eliminated by the registered EDF match within these fixed feature classes — never "not a capacity artefact"; not a state claim.

- `analysis_ctxoverlap_A.json` (444 s) / `analysis_ctxoverlap_B.json`
(595 s) / `analysis_ctxoverlap_joint.json` — **Round 34b (P/C
partial-overlap screen, static estimand): INCONCLUSIVE in both
sentinels and in the joint — the terminal rung** (ledger
`nlm007_round34b_sentinels`, `nlm007_round34b_joint`; commits `b285945`,
`21ecb3f`). `P+C − P` cosine A +0.0178..+0.0373, B +0.0238..+0.0355
(A/F4 point just below 0.02 but its upper interval exceeds 0.02) — the
redundancy STOP fails; residual-context (`C□→Δ□`) cosine ~+0.019..+0.089
with residual normalized-error gain negative in every ridge/kernel,
sentinel, F4–F20 cell — retention fails. Joint: COMPLETE/SCREEN-ONLY,
INCONCLUSIVE, no common retaining layer, no common stop layer. The joint
reducer's EDF<=rank bound was producer-inconsistent by ~3e-5 at excluded
F0 fits only; repair = post-outcome but not outcome-selective (audit
#22); producers, sidecars, and gate functions unchanged; no rerun. The
positive `P+C − P` increments are evidence against the registered
strict-redundancy account, not evidence for operational state. Under
the continuation ruling an INCONCLUSIVE rung is an allocation stop:
Round 34c (`itemctx_*`; implemented, never run) does not run and
NLM-007 closes (audit #22).
- **Round 36 — minimal operational-quotient world (the constructive
program; design registered in `theory/EXPERIMENTS.md` at `c26eee4`,
ledger `round36_design_registered`; run-ready `a383a45`):** runnable
CPU-only latent transition system on the 16 four-bit states with
toggle/swap/no-op, trained from behaviour only; identity = equality of
future response signatures under allowed actions (bisimulation);
falsifiers with registered thresholds (quotient well-definedness,
involution, non-commutation table, held-out 2/3-step closure,
interchangeability, cross-seed action-table invariance). One module
`experiments/run_operational_quotient.py` (`produce` / `reduce` /
`fixture`; retired `f6dac0e`), config `experiments/config/operational_quotient_v1.json` (retired);
producer/reducer separated; fixture before any produce.
**v1 first run — FAIL every gate** (commit `073037f`; ledger
`round36_first_run`; adjudication `e69ac72`, `round36_adjudication1`;
audit #23 `round36_audit23`). Artifacts
`experiments/results/operational_quotient_v1/`: `config.json`,
`manifest.json`, `evidence.json`, `verdict.json`, `weights.npz`.
`produce` (seeds 11/23/37/53/71, CPU, one process) 52.6 s (train 41.7 s,
evidence 11.0 s; wall 900 s); `reduce` FAIL on quotient availability,
quotient well-definedness, toggle involution, swap/toggle table,
held-out depth-2/3 closure, interchangeability, action-table truth
(0/5 seeds; 14–56% of 176 cells at `0.10/0.90`), cross-seed whole-table
gate. Behaviour: train 96.563–98.546%, held-out 97.009–98.259%, depth-3
93.8–96.3%, loss still falling at step 4,000. Licensed reading = the
audit #23 paragraph (verbatim in `STATE.md`): behavior-, calibration-,
and exactness-confounded non-certification; no fit-but-non-congruent

claim. DIAGNOSTIC only (confidence-free `p>0.5` replay, read-only): 148–174/176 truthful one-step action cells per seed (84.1–98.9%); cells identical across all five seeds 11/176 at the registered thresholds, 112/176 at `p>0.5`; 175/176 bitwise-majority table; every exact gate still fails.

- **Round 36b — behaviour-fit ladder (preregistered `f9dea33`; COMPLETE; audit #24):** four cells `S16` / `S64` / `LR64` / `W64` (16k/.003/w32; 64k/.003/32; 64k/.001/32; 64k/.003/64; configs `experiments/config/operational_quotient_36b_S16.json`, `_S64.json`, (retired `f6dac0e`) `_LR64.json`, `_W64.json`; walls 8/20/20/30 min; every cell run and visible; no pooling or best-cell). Locks before any outcome: V1 `f95ff01` (`round36b_lock`) -> review #1 NOT-READY `70b58a7` (`round36b_review1`: eligibility from producer aggregates) -> audit #23 amendment `9edb892` (three-stage status tree, DIAGNOSTIC `p>0.5` table, cellwise cross-seed accounting, depth traces) -> row-level logit replay, lock V3 `ff8eaa7` (`round36b_lock_v3`) -> review #2 RUN-READY (`round36b_run_ready`); runner + configs `61e2430`. Run (ledger `round36b_ladder`; `abef6cf`; walls 174/606/618/696 s): every cell `FAIL — BEHAVIOR UNDERFIT; QUOTIENT INELIGIBLE`. Fit (train / 21,184; held-out / 2,240; five seeds): S16 20,894–21,184 (1 exact) / 2,179–2,218; S64 21,078–21,184 (2 exact) / 2,184–2,226; LR64 21,088–21,184 (4 exact) / 2,198–2,225; W64 21,184 on all five seeds / 2,216–2,239 (98.9–99.96%, none exact; all misses H3, none common to all seeds). Artifacts `experiments/results/operational_quotient_36b_*/`: `config.json`, `manifest.json`, `verdict.json` committed; `evidence.json` (165–177 MB per cell) and `weights.npz` git-ignored (`.gitignore`: remote size limit), retained locally, sha256-pinned in manifest/verdict/ledger. Licensed reading = audit #24 (verbatim in `STATE.md`): eligibility not reached; reachability of the exact learned precondition unvalidated, not unsatisfiable. INFORMATIONAL only (W64, `p>0.5`): all 16 encoder identities and the truthful 176/176 canonical action table identical across five seeds; well-definedness 71–94%, involution 46–84%, H2 closure 98.6–99.9%, H3 closure 61–92%, interchangeability 39–77% — a cross-seed-stable canonical one-step skeleton, not a certified quotient/action algebra. A prospectively locked, post-outcome, outcome-informed successor: exploratory, not confirmatory; it cannot rescue or overturn v1.

- **Round 36c — quotient-trained positive control (COMPLETE; both cells FAIL; audit #25):** same carrier/seeds/representatives as 36b with explicit transition supervision (BCE + `1.0 *` MSE to the stop-gradient true-successor encoding over the 176 canonical transitions), `result_scope = POSITIVE-CONTROL`, unchanged exact reducer. Locks before any outcome: `round36c_registered_locked` -> review #1 NOT-READY / lock V2 (`round36c_review1_lock_v2`) -> review #2 RUN-READY (`round36c_run_ready`); runner + configs `dd699e2`. w32

(produce 819.8 s / 1800 s wall): FAIL on every exact gate in every seed, action-table truth 0/5, cross-seed table FAIL. w64 (conditional cell, precondition met; produce 987.6 s / 2400 s wall): FAIL — swap/toggle 4/5, depth-2 closure 3/5, all else 0/5. Artifacts `experiments/results/operational_quotient_36c_w32/` and `_w64/`: `config.json`, `manifest.json`, `verdict.json` committed; `evidence.json` and `weights.npz` git-ignored, retained locally, sha256-pinned. Adjudication (`round36c_w32_adjudication`): the combined loss trace deteriorates in seeds 11/53/71 after early minima, plateaus in 37, near-converges only in 23; paired regression vs width-matched behaviour-only S64 train counts localizes the regression to the added joint objective. Licensed reading = audit #25 (verbatim in `STATE.md`); the FAIL registers as "this reachability control did not reach the certificate", nothing stronger. Next: Round 36d (frozen-chart transition control, one capped cell), then Round 37 (presentation-duplicated 32->16 quotient world) — both registering, neither run.
- Round 34 capacity-matched state-versus-context audit (registered `d493cf2`, `theory/EXPERIMENTS.md`; implemented on the main analyzer as `--context-capacity-audit round34_v1`, commit `9eb1301`; ledger `nlm007_round34_registered`, `_impl_review1..3`, `nlm007_round34_producer_run_ready`): producer path RUN-READY; the joint claiming reducer is flagged for one further review (repair rounds on it: 3, cap reached). **Full six-arm run CUT by the continuation ruling (never run)**; previously HELD (audit #19, ledger `nlm007_audit19`): its primary estimand is `P_static`-residualized and cannot retroactively capacity-match `ctx_A`/`ctx_B`; its K=13 KL-rank endpoint must become diagnostic (raw continuous KL confirmatory) or the parked SVD gate must reopen before any outcome. **Round 34a — matched-EDF core screen** (Codex preregistration `f97a533`; tags `ctxcapA_raw` / `ctxcapB_raw` for the unresidualized estimand, `ctxcapA_static` / `ctxcapB_static` separately; token ridge/kernel only, state ridge bisected to the selected contextual EDF and to the 47/48 rank ceiling, same outer folds, cosine + normalized error with paired block-first crossed intervals, no completion): **RUN-READY at `6b93ff1`** after four Tier-1 rounds (ledger `nlm007_round34a_registered_implemented`, `_review1..3`, `_fix1`, `nlm007_round34a_run_ready`; sentinel artifacts non-claiming, joint reducer read-only, hash-bound per-cell evidence sidecars `round34a_evidence_<tag>.npz`). Audit #20: raw and static are separate required screens — raw stages the `ctx_A`/`ctx_B` comparison, static stages the `ctxS` and future consequence estimand; neither substitutes for the other and no cross-estimand verdict is permitted. Six runs: `ctxcapA_raw`, `ctxcapB_raw`, `ctxcap_raw_joint` (DONE, CONTINUE — see above), `ctxcapA_static`, `ctxcapB_static`, `ctxcap_static_joint` (RUNNING). Under the continuation ruling a surviving margin does not reopen full Round 34, Round 33, or a completion

comparison; it only licenses the conditional 34b rung.
- **Round 34b / 34c (audit #20; preregistered by Codex in `theory/EXPERIMENTS.md`, `3b49321` / `ff69d82`, ledger `nlm007_round34bc_registered`):** before interpreting the static collapse as contextual redundancy and before the full Round 34, a cheap same-fold `P_static`/context partial-overlap screen (`P`, `C`, `P+C`, `C_perp -> Delta_perp`, same-EDF `X_perp` reference, context-to-`P_static` alignment; 34b, tags `ctxoverlap_A` / `ctxoverlap_B` / `ctxoverlap_joint`) and an item-embedding-by-`P_static` X-free comparator (`P_static` + 16 calibration-only item-embedding PCs + 160 interactions + boundary/POS floor; 34c, tags `itemctx_A` / `itemctx_B` / `itemctx_joint`). **Implemented on the main analyzer (`round34b_overlap_analysis`, `round34c_itemctx_analysis`; ledger `nlm007_round34bc_implemented`), UNRUN, under Tier-1 repair:** review #1 NOT-READY on four items — leakage provenance validated by counts rather than exact fold identities, clamped global `cos_rows` admitting undefined-cosine cells, NaN able to win inner selections with feature-dimension telemetry not locked, walls checked only per outer key (ledger `nlm007_round34bc_review1`; repair round 1 of 3; fix pass 2 + re-review #3 = repair round 3 of 3 in flight, ledger `nlm007_round34bc_fix2`). Under the continuation ruling both are CONDITIONAL rungs of the terminal ladder: 34b only if both 34a estimands CONTINUE and this final repair is RUN-READY without scope expansion; 34c only after a 34b CONTINUE. Full Round 34 and Round 33 are cut.
- **Round 35 — typed truth-evaluable world (docs-only design, `c74bfab`; ledger `nlm007_round35_design_registered`):** four-bit finite world (toggle/swap/no-op), population and linguistic-adversary contracts, frozen forced-choice yes/no log-odds, wrapper and same-length controls, causal patches, inherited X-free ladder, involution and one non-commuting composition, CPU-only budget. Authors nothing. Under the continuation ruling it is a **requirements envelope only** (right direction, wrong first artifact); the constructive program is Round 36.
- SVD telemetry / shadow-backend gate — **parked and unpassed** after re-review #4 (ledger `nlm007_svd_telemetry_review4`): a discretionary allocation decision under the global CLAUDE.md §2.7 repair-round cap, not an AGENTS.md rule (audit #18). Every low-rank / K=13 KL-rank claim keeps its amendment qualification; the analyzer diff stays uncommitted.
- Round 33 multi-position consequence instrument (runner `capture_forward_consequence`, analyzer `--source forward_consequence`; ledger `nlm007_consequence_impl_pending_review`, `_review2`, `_review3`): **implemented, unrun, PARKED and unpassed** (ledger `nlm007_consequence_instrument_parked`): re-review #3 found the reducer did not enforce six keys jointly positive across both horizons (closed); re-review #4 NOT-READY on base-compat schema mirror / preflight, serialized-fit fingerprints, wall rechecks, and a real CPU parity run —

the fourth consecutive repair round, so the global CLAUDE.md §2.7 repair cap was applied as an allocation decision (instrument lives on branch `conseq-instrument`; main analyzer stays at HEAD; raised to the user; parked, not killed). No consequence run is authorized; even after repair a pass licenses only persistence of downstream predictive accuracy under frozen tails (audit #18). Audit #19 upheld the parking as allocation, not a kill: review #4 still found a real legacy-manifest crash, unproved exact-fit reuse, incomplete preflight/binding, wall gaps, and missing CPU parity; the branch is salvageable only if a later matched-capacity result makes the consequence test worth reopening. **CUT by the continuation ruling:** branch archived as tag `archive/conseq-instrument-parked`, not deleted; its legacy-parity question was answered (IDENTICAL) but no CONTINUE reopens it.

- `analysis_xf{SA,SB,AA,AB}.json` — Round 27 comparator 2, the **registered X-free field** (`--xfree-field`: calibration-only residual-space field from `P_static` + the rank-4 carrier-summary scores + 16 frozen-embedding PCs + 64 interactions, no cell-level `X□`, with a df-matched state ridge; ledger `nlm007_xfree_field_predeclared`, `nlm007_xfree_comparator_implemented`, frozen at analyzer `cddcd47` with the literal command in `nlm007_xfree_comparator_frozen`). Four cells, 7200 s each; "registered", not "fair" (audit #15: the fixed rank-4/full-prefix omissions remain substantive). **Disarmed** (ledger `nlm007_xfree_chain_disarmed`): the armed chain was killed under the Round 29 order and sits behind the external-axis probes. No artifact.
- `analysis_fl{SA,SB,AA,AB}.json` — Round 27 comparator 1, the fully refitted Freedman–Lane residual-geometry null (`--fl-null 20`: layer-level exact test, common cell mask, ridge-only inner grid; ledger `nlm007_freedman_lane_predeclared`, `nlm007_flnull_comparator_implemented`). **Ready, not armed**: Round 29 (adopting audit #15) limits it to one conditional A-static cell, run only if the external-axis probes leave the state reading live. No artifact.
- `experiments/config/lexical_probe_fresh_v1.json` — Round 29 probe-2 population (ledger `nlm007_fresh_population_frozen`): four families question / instruction / comparison / enumeration, 8 matched presentation pairs + 4 operational control pairs, same 80 words; ` not` (id 537) is a single token on every prefix. Prospectively authored and committed before any new capture or score, not independently blind to prior results; the declared digest `c6edaa92…` is not the raw file SHA-256 (`12c72401…`). **Design-void for confirmatory probes 2–4 (audit #16)**: no pair establishes presentation-only equivalence across all four word classes, and several change syntactic licensing, modality, definiteness, degree, or quantification. Retained unchanged as an exploratory mixed-frame stress set only; no post hoc subset rescue is confirmatory. No capture. Successors: v2 and v3 (voided), v4 (frozen)

below.
- `experiments/config/lexical_probe_fresh_v2.json` — Round 31 population (`79c8628`; Codex as outcome-blind author; `Please/Kindly | For reference,/For clarity, … plan to {repeat|omit|capitalize|reverse} the word <X>`; tokenization pre-check passed). **Voided** by the independent linguistic adversary (ledger `nlm007_fresh_v2_voided`, erratum `nlm007_erratum_v2_void_count`): all 16 pair-2 cells fail — "For reference" vs "For clarity" introduce distinguishable discourse purposes that can scope over the operation; the 16 pair-1 cells and the 16 control cells pass. Retained unchanged as a pragmatic-purpose stress set (audit #17: not a dead file). No capture.
- `experiments/config/lexical_probe_fresh_v3.json` — Round 31 population (`a8b14a8`, fresh session; Please/Kindly; ASCII vs typographic apostrophe). **Voided** on control edit-magnitude (ledger `nlm007_fresh_v3_voided`): all 32 presentation pair cells passed (apostrophe rated near-degenerate), but the 8 controls under the orthographic wrapper fail clause 6 (a whole-word operation swap vs a one-glyph presentation edit) — a control-design failure only (audit #17). Retained unchanged, descriptively. No capture.
- `experiments/config/lexical_probe_fresh_v4.json` — Round 31 population (`afd6fcc`, fresh outcome-blind author): `{Please|Kindly} plan to OP the word <X>` and `{Hello,|Hi,} please plan to OP the word <X>`, OP □ {repeat, omit, capitalize, reverse}; aligned surface-word edit distance = 1 for every pair and control; frozen `operation_updates` block. **Approved 48/48 by a separate fresh adversary session (outcome-blind procedural approval: grammaticality, preservation of the explicit string-edit instruction, matched surface-word distance under the common mention frame — not 48 independent linguistic observations); tokenization pass; frozen** (`3a70890`, ledger `nlm007_fresh_v4_frozen`): raw sha256 `f813f9b2cb96546726412b55857e79324ac23b47a2cb6418f8569ce47bbc5d33`, git blob `8845f75c89c27d8db9c5f5cc8a11cfd109b4756b`; captures must pass `--expected-config-sha256`; any edit voids the approval. The config's top-level "not approved for capture" note is historical authoring-time text superseded by the structured approval/hash fields (erratum `nlm007_erratum_v4_config_note`). Audit #17: the approval licenses a bounded mentioned-string instruction micro-world (every item in the autonymic `the word <X>` frame), not presentation inertness across ordinary noun, verb, adjective, and function-word uses; v4 sentinel results are a fresh-population stress test of the same append construction, never pooled with `lm_dyn_v1`. No capture; chain `run_v4.cmd` not armed (requires the operation-update and bridge code to pass Tier-1 review).
- Contextual-prefix X-free baseline (`eab0a68`, Round 31; analyzer `--contextual-prefix-xfree` / `--ctx-screen`, token_ids_v1, point-only screen; ledger `nlm007_ctxprefix_implemented`): screens scored

(`ctxscr_A/B` above); completions running/queued.
Operation-verb update capture stage (`capture_op_update`) and the
no-model acceptance fixture `op_update_fixture.py` committed
(`d9a6cca`); the analyzer side (`--source op_update`) and the
bridge-ladder patch: uncommitted, under Tier-1 review. Audit #17: the operation-verb
update is a declared-operation-verb context intervention, not yet a
denizen-enacted operational move (source and recipient are separate
prefix encodings; no execution consequence is measured).
- `run_r31.cmd` (probe-1 screens, `P_aug-full` cell A, contextual-prefix
screens and completions on `lm_dyn_v1`): **disarmed** (ledger
`nlm007_r31_chain_disarmed_pending_svd_gate`) — Round 32 forbids further
low-rank output before the SVD telemetry / shadow-backend gate passes
Tier-1 numerical review. No artifact.
- Capture extension (`4137258`, Round 30; no artifact): `run_lm_dynamics.py`
gains a config provenance guard (`--expected-config-sha256`), the ` not`
operator-insertion capture, repeat-noise arrays, and population-void
hard controls. RUN-READY; nothing captured under it yet.
- `analysis_unseensmoke.json` — `--unseen-words 2` pipeline smoke at F8, A
(1 shuffle / 10 boot; ledger `nlm007_unseen_smoke_F8A`, overwritten by
`nlm007_unseen_smoke2_F8A` with the audit #10 lexical nulls and the
K = 11 rank universe). **Not a result**; the full run awaits Codex
predeclaration.

 **Successor endpoint (valid in all runs).** L0→L1: word-mean = ridge =
kernel = 0.949, shuffled null 0.95 — lexical persistence, no law beyond
word identity. From L4 on, full-dimensional ridge beats word-mean and the
best static chart at every depth (ridge/chart/word-mean: L4 0.927/0.884/
0.886; L8 0.941/0.860/0.861; L12 0.977/0.898/0.888; L20 0.965/0.901/0.897;
L27 0.976/0.883/0.864, the last on normed vectors). Shuffle penalty grows
with depth.

 **Slot-endpoint gate reading (Round 17, superseded at L8/L12 by Round 18).**
On `analysis_slot.json` the pairs L8→L9, L12→L13, L27→L28 cleared every
locked gate mechanically (support 1.0); L4→L5 and L20→L21 cleared both slot
readouts and the word-mean gate but missed the all-fold +0.05
successor-cosine lead (a stricter convention than the original lock, audit
#6); L0→L1 fails every lead gate. Word-mean slot skill decays with depth
(0.95, 0.84, 0.78, 0.70, 0.43, 0.40) while ridge holds 0.92–0.98 and the
chart collapses late (0.50, 0.51). Round 16 scorecard: five of six
predictions held; the L27→L28 attenuation prediction failed.

 **Withdrawal at L8→L9 and L12→L13 (Round 18 + audit #7; ledger
`nlm007_baselines_v1`).** Pooled ridge − identres on successor cosine /
slot skill / slot ordering: L8 −0.008/−0.021/−0.020; L12 −0.007/−0.009/
−0.013 (only slot skill and ordering are completed-law slot metrics). On
shared words and held-out carrier blocks, identity-plus-shared-displacement
is at least as good as full ridge within a post-hoc one-sided 0.02 pooled
margin on the three recorded comparison metrics at L8→L9 and L12→L13; the

finite-ladder ridge wording is withdrawn as a conservative policy. The intervals support "no demonstrated positive ridge advantage under this margin", not "no lead" or equivalence. The measured relation is consistent with identity plus a calibration-mean displacement under this design; the experiment does not determine whether the displacement is carrier-, state-, or word-dependent. The Round 17 two-pair criterion does not survive as a claim. Identity-plus-shared-displacement does not meet the chosen margin at L0 (+0.46), L4 (+0.033/+0.019/+0.022), L20 (+0.018/+0.034/+0.032), or L27; L4 and L20 remain non-qualifying but live, while L27 is not a valid raw-residual persistence comparison. Per-carrier affine is far below the cross-carrier field everywhere (within-carrier diagnostic only).

- **Displacement ladder (Round 19 + audit #8; `analysis_delta.json`).** Only `L20->L21` passes the predeclared three-endpoint gate (kernel; positive clustered lower bounds on displacement cosine, slot skill, slot ordering) — retained as one bounded qualifying pair under the registered displacement-and-slot-law gate. `L0` is lexical persistence. `L4` has a small live remainder but fails the gate. `L8/L12` separate strongly from the word-conditioned displacement mean on displacement coordinates, with kernel minimal among the tested ladder, but slot-ordering leads are only 0.003–0.022 and slot-skill lower bounds are mixed — the gate fails. Adopted wording: held-out-carrier evidence for predictable displacement variation beyond a word-conditioned mean, with a kernel as the minimal tested predictor; carrier/template versus state dependence remains unresolved. The carrier shuffle is a carrier-alignment diagnostic, not a state-independence null (shuffled field reported for ridge/low-rank only). "The slot law barely registers it" is a readout fact, not a world fact.

- **Forward-time move (Round 20 + audit #9; `analysis_fwdA.json`, `analysis_fwdB.json`).** Sentinel '.': `F0` token-identity dominated (shared mean = word-conditioned mean = 0.67 ≈ field 0.69). `F4/F8/F12`: displacement cosine ridge/kernel 0.71–0.78 vs word-conditioned mean 0.48–0.53; law skill at the sentinel position 0.39–0.57 vs 0.01–0.02; carrier-shuffled field 0.12–0.32 vs 0.67–0.81; but ordering leads 0.00–0.08 with lower bounds ≤ 0 in half the folds — three-endpoint gate fails. `F20` qualifies (ridge: +0.16–0.23 / +0.50–0.61 / +0.020–0.058, all LBs > 0). Sentinel ',': same shape; `F12` and `F20` qualify (ridge), `F8` misses one ordering LB by −0.002, `F4` one skill LB. Token-identity control: the '.'-fitted predictor on the ',' target scores 0.43–0.54 vs 0.26–0.30 for the shared mean. Adopted wording: the period sentinel did not meet the preregistered two-layer, three-endpoint qualification criterion — a nonpass under the historical contract, not a kill of forward transport; in the shared-word, held-out-carrier design, sentinel displacement is predictably improved over the word-conditioned mean from F4 onward and the response law registers that variation in cosine and skill; the ordering endpoint was later diagnosed as insensitive/saturated, so the qualification failure is not a substantive null result. The comma

arm falsifies "token identity or position prevents any qualifying layer". Carrier/template presentation versus state dependence remains unresolved (audit #8). Ordering is replaced prospectively by KL-to-truth candidate rank (K = 10); no existing run is reclassified.

- **Within-style-family null, sentinel '.' (`analysis_styleA.json`; diagnostic only).** Mechanically `F4/F8/F20` beat both the word-conditioned mean and the null on cosine, skill, KL-rank (ridge KL-rank 0.82–0.90 vs word-mean 0.31–0.41); `F12` misses one fold's KL-rank LB; `F0` fails. The null collapses below the shared mean (0.16–0.50 vs 0.47–0.62). Audit #9: a field refit on a broken carrier pairing predicts the wrong carrier's displacement, so "beats the within-style null" is not informative evidence for a state-linked component; "style-robust" is withdrawn as a claim. The KL-rank endpoint here ranked K = 7 (kNN-1/5/20 omitted; fixed in `269e46c`) and is not contract-valid. Sentinel ',' (`analysis_styleB.json`) has the same shape: `F8/F12/F20` mechanical, same label, same verdict.
- **LOCO control, sentinel '.' (`analysis_locoA.json`; Round 21 rule; adjudicated Round 22).** Pooled ridge − per-word block mean: `F4` +0.126 / +0.313 / +0.300, `F8` +0.118 / +0.232 / +0.292 (cosine / law skill / K = 4 KL-rank), `F12` and `F20` in the same range, all lower bounds > 0.08, 11–15 of 16 held-out carriers passing all three; `F0` no pass (block mean ≥ ridge). Audit #10 wording: on already-seen words, within a style family, X predicts a held-out carrier's displacement and response-law consequence better than the three-carrier per-word family mean at F4–F20 — not a presentation-independent state or a native law. The baseline is variance-disadvantaged; equalized X-free lexical baselines (word-only ridge, shrunk word mean) are required before interpretation; LOCO does not separate state from a smooth carrier/style code; the pooled 16-carrier bootstrap is secondary. `F0` = "no detected conditional gain".
- **LOCO control, sentinel ',' (`analysis_locoB.json`; Round 22, audit #11).** `F12/F20` pass (pooled ridge − block-word mean: cosine +0.07–0.10, skill +0.15–0.20, KL-rank +0.20–0.26, lower bounds > 0; 12–13 of 16 carriers); `F4` misses skill and KL-rank; `F8` misses skill only (KL-rank LB +0.021); `F0` fails. Run-level positive (2/5); weaker in breadth than A — a sentinel-specific instrument result, not evidence that B carries less state information. Same audit #10 wording as A.
- **Equalized LOCO addendum, sentinel '.' (`analysis_locoeqA.json`; defect-affected, audit #11).** All 80 folds selected maximal shrinkage (`lam_wordonly = 100`, `alpha_shrunk = 1`), i.e. the equalized baselines equal the shared mean; ridge − equalized baseline at `F4–F20`: cosine +0.09–0.13, skill +0.23–0.30, KL-rank +0.26–0.34 (11–14/16 carriers); `F0` negative. **Descriptive only:** the inner centre included the validation carrier and the comparator was chosen on held-out outcomes, so "the data selected maximal shrinkage" is invalid as implemented; whether maximal shrinkage persists under the corrected centre is unknown. Withdrawn (audit #11): "no per-word lexical signal", "variance objection answered",

"context not content", "the state-conditioned component is large". Adopted wording: the word-conditioned component captured by the tested estimators is negligible for the measured forward displacement in this design; the positive object is X-conditioned residual predictability.

 **Corrected equalized LOCO addendum (Round 25 + audit #13; `analysis_locoeq2A.json`, `analysis_locoeq2B.json`).** With the inner two-carrier centre and the comparator frozen by calibration score, the equalized baselines no longer collapse onto the shared mean: A's calibration-selected equalized comparator sits roughly 0.002–0.009 above it, B's 0.002–0.007. A: `F4/F8/F12/F20` pass against the equalized comparator (cos +0.09–0.13, skill +0.23–0.31, KL-rank +0.30–0.43, lower bounds > 0.08; 11–14/16 carriers), `F0` fails — Round 25: a valid mechanical positive for the bounded sentinel-A seen-word within-family diagnostic; audit #13: audit #11's inner-centre *defect* concern is resolved by the corrected sentinel-A data (not "audit #11 is resolved"); the pooled equalized interval is secondary. B: `F12/F20` pass, `F4/F8` miss on skill/KL-rank lower bounds (cosine leads hold), `F0` fails; run-level positive (2/5); adjudication pending. Both arms agree with the defect-affected runs' numbers (baselines moved by ≤0.01, no verdict changed). Maximum wording (audit #13): "On already-seen words, within sentinel A's style-family design, the context-bearing X field predicts the held-out carrier's forward displacement and response-law consequence beyond the properly nested, calibration-selected X-free lexical comparator at F4–F20." Still withdrawn: "no per-word lexical signal", "context rather than content", "the state-conditioned component is large", any presentation-independent or native-law reading.

 **Unseen-word runs (Round 23 + audit #12; `analysis_unseenA.json`, `analysis_unseenB.json`).** Calibration and held-out word identities disjoint; the class-mean and frozen-input-embedding `wordonly_knn` nulls sit at the shared mean at every layer. Block-first pooled ridge − stronger X-free lexical null: A cos +0.14–0.19, skill +0.33–0.47, K = 11 KL-rank +0.35–0.57 (lower bounds > 0.12; full-gate keys 7/8, 7/8, 8/8, 8/8 at F4/F8/F12/F20); B cos +0.11–0.17, skill +0.31–0.41, KL-rank +0.31–0.52 (lower bounds > 0.09; 5/8, 6/8, 8/8, 8/8). `F0`: A's continuation block collapses, B's cosine lead 0.018 is below the 0.02 point gate — audit #12 wording "non-qualifying, with the continuation held-out block providing the strongest local failure pattern". Round 23 adjudication: the state-linked prediction is held only as X-conditioned residual predictability, generalizing across unseen word identities; the tested lexical-interpolation prediction fails; the presentation/style nuisance prediction remains live. Audit #12: the predeclared class-preserving word bootstrap was not implemented (words resampled without class strata and nested within blocks) and the lexical null family is weak, so the status is **mechanical pass under the recorded reduction; formal gate pending a contract-correct bootstrap** and stronger nulls (nested

frozen-embedding→Δ ridge, nested embedding-conditioned kernel, k ladder). Adopted wording: "not exact held-out-word lookup and not the tested lexical interpolator" — never "not word lookup" or "not lexical" unqualified; "the tested lexical nulls fail", not "lexical content is absent"; the ~0.06 seen→unseen drop is a point comparison at F8 only; positive object = X-conditioned residual predictability transferring across the held-out word fold and held-out block. Strongest alternative: `X` contains smooth lexical and presentation coordinates along which the later displacement varies; the coarse nulls collapse for coarseness, not because the variation is operational state.

 **Residualization A-static (Round 26 as corrected by audit #14; `analysis_resSA.json`).** Sentinel A, `P_static` (centred block one-hot, tokenized lengths, slot/sentinel positions) cross-fitted out of both `X` and `Δ`; two unseen-word folds; K = 13; crossed class-preserving bootstrap. `F4/F8/F12/F20` pass the residual-vs-null gate: `X` ridge residual cosine 0.56–0.62 vs 0.06–0.07 for the strongest residualized X-free null; block-first margins cos +0.50–+0.56, skill +0.31–+0.48, KL-rank +0.40–+0.61 with positive lower bounds; full-gate keys 7/8, 7/8, 6/8, 8/8 (misses family-localized in gloss/association; the four checkpoints are correlated measurements, not replications); no block collapse. `F0` fails (negative pooled skill; association-block collapse) — "no qualifying conditional gain at F0 under this instrument", a genuine negative control. Not a cosine-geometry mirage (audit #14): the ridge cosine falls from raw 0.65–0.76 to residual 0.56–0.62 while the nulls fall to ~0.06; shuffled q95 ≤ 0.13; residual normalized error 0.78–0.83. Registered-static-metadata arm (`P_static→Δ`): held-out cosine 0.43–0.63 by layer — a cosine, never a variance share, fraction, or "explains 42%"; not a pure presentation component (audit #16). Adopted ruling: "`P_static` took the non-collapse branch. Locally, the result establishes registered-presentation sensitivity and survival of X-linked residual predictability after cross-fitted removal of those registered coordinates. It identifies neither the surviving field as operational state nor the result as presentation-independent." Withdrawn (audit #14): Round 26's "much of the raw lead may have been presentation-mediated" — the overlap between presentation and the raw ridge lead is not identified. Retention: "the predeclared robustness marker is mechanically met" only (audit #13; pre-patch analyzer; patched rerun `resSA2` queued). The gate is too easy for a state claim: a fully refitted Freedman–Lane residual-geometry null and a flexible calibration-only presentation/ lexical comparator are to be preregistered before any state reading. `P_static` pass plus `P_aug` collapse remains the predeclared "static coordinates incomplete, not state" branch.

 **Residualization A-augmented (Round 27 as corrected by audit #15; `analysis_resAA.json`).** Sentinel A, `P_aug-score4` cross-fitted out of both `X` and `Δ`; same folds, K = 13, bootstrap and raw-shadow arm as

A-static; common-scale retention block present. All five correlated checkpoints meet the registered aggregate residual-vs-null gate. F4–F20: `X□` ridge residual cosine 0.56–0.62 vs 0.06–0.07 for the strongest residualized X-free null; block-first margins cos +0.50–+0.56, skill +0.35–+0.46, KL-rank +0.43–+0.56 with positive lower bounds; full-gate keys 8/8, 7/8, 6/8, 8/8; no block collapse. F0 is qualitatively weaker — residual cosine 0.34 vs −0.01, skill +0.16 [LB 0.02], KL-rank +0.30 [0.12], only 2/8 keys clear the full per-key gate — and is not an independent confirmation of the F4–F20 profile; the raw F0 transition remains identity/token dominated (raw ridge exceeds the raw null by only ~0.019 cosine). `P_aug` carrier-summary nuisance arm (`P_aug → Δ`) 0.45–0.64 cosine by layer; because its scores are derived from carrier-level `X`, this is not a presentation-only estimate or a variance share. Common-scale retention: the paired bootstrap median of the reassembled residual-model margin over the raw-ridge margin exceeds 0.5 in every layer-endpoint cell; 14 of 15 interval lower bounds exceed 0.5 (F4 continuous KL 0.495), so no uniform 95% claim; ratios above one do not show strengthening. Reading (audit #15): A-static and A-aug are nested sensitivities on the same sentinel-A cells, not independent replications; the registered static and rank-4-score nuisance fits do not absorb the `X□–Δ□` association; broader presentation, carrier-geometry, and prefix-fingerprint explanations remain fully live. Neither result identifies operational state, presentation independence, fresh-style transfer, composition, or a native law. Strongest alternative missed by both queued comparators: a high-dimensional prefix/carrier fingerprint (aligned, cell-level, compatible with unseen-word transfer and law improvement).

□ **Residualization B-static (Round 28; `analysis_resSB.json`).** Sentinel ',', `P_static`, same contract as A-static, common-scale field present. `F4/F8/F12/F20` pass the residual-vs-null gate: `X□` ridge residual cosine 0.52–0.58 vs 0.06–0.09 for the strongest residual null; block-first margins cos +0.45–+0.50, skill +0.35–+0.42, KL-rank +0.40–+0.58; 8/8 positive keys at every passing layer; no collapse. `F0` fails (cosine lead +0.27 but pooled skill negative — the −7.5 skill is driven by two association folds near −30, locally ill-conditioned normalization, not uniform failure — and KL-rank lower bound < 0; gloss and association collapse), as under A-static. Registered-static-metadata arm (`P_static→Δ`) 0.41–0.63 cosine by layer (a cosine, not a variance share or a pure presentation component).

Common-scale retention passes at the bootstrap median for every F4–F20 endpoint; F4 continuous-KL lower bound 0.426 blocks a uniform interval claim; joint static retention awaits `resSA2`; the ratios are robustness ratios, not retained signal, state, or mediation. Ruling (Round 28 as corrected by audit #16): across the correlated A/B static runs, registered block/length/position metadata predict raw

displacement, and `X□` retains predictive association with `Δ□` beyond four X-free lexical nulls at F4–F20. This is a two-sentinel robustness result within one decoder and authored population — a correlated second-sentinel check, not independent replication, state, presentation independence, mediation, or a native law.

□ **Residualization B-augmented (Round 32; `analysis_resAB.json`; amended-implementation, SVD-telemetry-incomplete).** Sentinel ',', `P_aug-score4`, same contract as A-augmented; third launch with the SVD fallback. `F4/F8/F12/F20` pass the residual-vs-null gate: `X□` ridge residual cosine 0.52–0.57 vs 0.06–0.09 for the strongest residual null; block-first margins cos +0.46–+0.51, skill +0.40–+0.44, KL-rank +0.45–+0.54; 6–8/8 full keys; no collapse. `F0` fails (cosine +0.33 but skill lower bound −0.04; 4/8 full keys; gloss collapse). Registered-static-metadata + carrier-summary nuisance arm (`P_aug→Δ`) 0.42–0.64 by layer (not a presentation-only component). Same-run common-scale ratios exceed 0.5 at the median at F4–F20 (F0 wide). Only the ridge-only cosine and skill margins are mechanically reportable; the K = 13 KL-rank endpoint and every low-rank interpretation remain amendment-qualified (Round 32). Reading (audit #17 wording): the sentinel {A,B} × {P_static, P_aug-score4} table is complete only for the residual-versus-four-word-only-null mechanical gate: F4–F20 pass in all four correlated cells, while F0 fails except for a weak pooled A-score4 association with only 2/8 full-gate keys. This is consistent within-decoder, within-population condition robustness, not replication.

□ **Oracle defect (ledger `nlm007_oracle_defect_forward`).** The per-carrier oracle read the stored states directly; in forward and delta mode it predicted X from X, so the ~0.98 oracle values in `analysis_fwdA/B`, `analysis_styleA/B`, `analysis_locoA/B` are meaningless. Fixed prospectively; diagnostic only, no result changes.

□ **What we learned.** Identity is the null for residual-stream transport. The present data support persistence plus a calibration-average displacement as a competitive finite-design description at L8 and L12, retain small unresolved remainders at L4 and L20, and do not yet establish a native or generally reusable affine law. The forward step is a bounded held-out-carrier displacement-forecasting result that does not yet distinguish a state-space regularity from a carrier/template-conditioned nuisance law. A permutation null that a flexible model trivially beats is not a control. Within one style family the state carries predictive variation beyond the family's per-word mean for seen words (LOCO A), which narrows but does not remove the carrier/template alternative; the positive object is X-conditioned residual predictability (audit #11). On words never seen in calibration the same object transfers across the held-out word fold and held-out block against the tested X-free lexical nulls — a mechanical pass whose formal gate awaits a contract-correct bootstrap and stronger lexical nulls (audit #12). The corrected equalized

addendum removes the audit #11 defect without changing any verdict (Round 25, audit #13). Residualization runs may state only that the predeclared robustness marker is mechanically met until the common-scale retention marker is scored (audit #13). After cross-fitted removal of the registered static presentation coordinates, `X□` still predicts `Δ□` and its reassembled consequence beyond the residual X-free lexical nulls at F4–F20 — registered-presentation sensitivity plus surviving X-linked residual predictability, with the presentation/raw-lead overlap unidentified (Round 26 as corrected by audit #14). The same survival holds for the second sentinel under `P_static` (Round 28) and, on the same sentinel-A cells, under the nested rank-4-score `P_aug` fit (Round 27 as corrected by audit #15) — correlated sensitivities, not replications; the registered nuisance fits do not absorb the association, and presentation, carrier-geometry, and prefix-fingerprint accounts remain live. Bounded to one decoder and one authored template population. The fourth cell (B-augmented, Round 32) completes the sentinel {A,B} × {P_static, P_aug-score4} table for the mechanical residual-vs-null gate only — F4–F20 pass in all four correlated cells, F0 fails except for a weak A-score4 association — and licenses within-decoder, within-population condition robustness, not replication; its low-rank content is amended-implementation and SVD-telemetry-incomplete until the telemetry gate passes (audit #17). Audit #17's allocation ruling (adopted Round 33; supersedes the Round 29 and Round 31 orders): protected work (`resSA2`, the SVD telemetry gate) → the contextual-prefix X-free baseline → one bounded multi-position consequence test (next k □ {4, 8} tokens, teacher-forced) BEFORE the v4 bridge/interchangeability probes and before a second decoder; do not author a v5 — the next population, when one is authored, is a typed use-frame task. Behind it, disarmed or conditional: the Round 31 chain (probe-1 screens, `P_aug-full` A cell, contextual-prefix screens), the registered X-free field ×4, Freedman–Lane on A-static only, the second pinned decoder. Further lessons: a numerical instrument that fails to converge is a finding about the instrument until diagnostics say otherwise (B-aug) — and every low-rank result now sits behind a telemetry gate; a template population must pass a predeclared linguistic contract before any capture, or the presentation axis it is meant to test is not defined (audit #16); the v1–v3 loop showed that an all-inventory ordinary-use presentation contract had not been achieved — v4 obtains grammatical core-operation equivalence by placing every item in the same autonymic `the word <X>` frame, which licenses a bounded mentioned-string instruction micro-world and nothing wider (audit #17); an instruction-verb edit without a measured execution consequence is a declared-operation-verb context intervention, not an operational move (audit #17).

## Round 12 closure — frozen-encoder program closed; pivot to worlds with dynamics (2026-08-27)

 Ledger `nlm006b_round12_adjudication`; dialogue `theory/dialogue/003.md`; commit `3294718`. NLM-006b corrected to non-diagnostic under its own label-preservation gate (below); frozen-encoder closeness/map work closes as scope management.

 **Residue (narrow, this encoder/dataset).** Training supplies a task-effective chart metric, affine-path smoothness, and graceful chart degradation under identity-destroying moves; no native construct tested (substitutability profiles, Fisher pullback, their transported variants) competes with it. Not a general claim about native constructs.

 Next program: causal-LM residual streams, where the forward pass is the world's own transport (NLM-007).

## NLM-006b — calibrated transport audit; chart survives, NON-DIAGNOSTIC under lock (2026-08-28)

 **Design.** Locked Round 11 (`nlm006b_prereg_transport_audit`): independent candidate strata (20 same-/20 cross-fine-label per anchor), transported-pair predictors F_T / R_T vs cosine_T / euclid_T on (T_e x, T_e y), true fine-label endpoint, label-preservation gate p_e ≥ 0.80, calibrated displacement gate. Ledger `nlm006b_v1`; artifact `experiments/results/nlm006b_v1/analysis.json`; transports `experiments/results/vision_cifar100_dinov2s_edits_v2/` (edits.npz git-ignored, sha256 9cc0e7c0…; displacement.json committed). 471 s, CPU.

 **Chart survives every displaced transport.** Support 400/400; displacement gate passes for crop50/invert/mix50/occlude50 (0.98–1.0 above control q95). TT chart lead over best native: crop50 +0.208, invert +0.227, occlude50 +0.222, mix50 +0.090 (paired CIs exclude 0).

 **Non-diagnostic (Round 12).** Label preservation 0.19–0.46 for all four displaced families vs the 0.80 gate (controls hflip 0.77, shift 0.76): every family is OOD under the identity gate, so chart survival is descriptive only and no native/chart verdict is issued.

 **Order effect.** ST−TS cosine ≈ 0.035 for all displaced families (CIs exclude 0); ≈ 0 for hflip. Real, small, outside the invariance class only.

## NLM-006 v1 — transports outside the invariance class; EXPLORATORY (cosine-selected negatives) (2026-08-28)

 **Design.** Six transport families re-encoded by the frozen encoder (`experiments/results/vision_cifar100_dinov2s_edits_v2/edits.npz`, keyed `test_emb_<family>`: hflip, shift1px, crop50, invert, mix50, occlude50; `displacement.json` alongside), stratified candidates, true fine-label endpoint. Relabeled **exploratory** by Tier-3 audit #3 before results were read: hard negatives were cosine-selected, so the pool is adversarial to any chart-like ranking. Ledger `nlm006_v1_exploratory`; artifact `experiments/results/nlm006_v1/analysis.json`.

 **Uninterpretable for the primitive contest.** Every predictor scores below 0.5 (cosine 0.411, Euclid 0.402, F 0.486, R_no_coarse 0.477) — cosine's "collapse" is manufactured by selecting negatives with the tested metric.

- **Exploratory signal.** Support 400/400 (stratification fixes NLM-005's support failure). Order sensitivity appears only outside the invariance class: ST−TS cosine 0.05–0.10 with CIs excluding 0 for crop50/invert/mix50/occlude50; 0.00 for hflip/shift1px. Displacement mean cos: hflip 0.96, shift 0.98 vs crop 0.63, invert 0.49, mix 0.43, occlude 0.66.
- **Next.** NLM-006b (ledger `nlm006b_prereg_transport_audit`): independent candidate strata, transported-pair predictors, label-preservation and calibrated displacement gates. Lesson: candidate pools must never be selected by the metric under test.

## Round 10 closure — frozen-encoder closeness/map line closed (2026-08-27, narrowed by audit #3)

- Ledger `round10_frozen_chart_closure`. The NLM-003 R-over-F claim is withdrawn (coarse-taxonomy leak, see diagnostics below); NLM-005 is void on support; no native construct built so far (substitutability profiles, Fisher pullback) competes with the trained chart metric on this artifact.
- **Residue as narrowed by Tier-3 audit #3:** training creates a task-effective chart and affine-path smoothness *in this encoder/dataset* (cosine 0.946 trained vs 0.575 random-init; same-class chart-line flicker 12.7% vs 95%). Not a general claim that native constructs are dominated, and not proof of intrinsic geometry or of "straight routes inherited from training" beyond this encoder and dataset.
- Replacement line: NLM-006/006b — stratified transports outside the trained invariance class.

## NLM-005 — composed transport/substitution; VOID on support (2026-08-27)

- **Design.** Locked `a12aad4` (artifact lock `aab0f69`). hflip and 1-px-shift transports re-encoded by the frozen encoder, composed with random substitutions in both orders (ST, TS), true fine-label endpoint. Ledger `nlm005_v1_composition`; artifact `experiments/results/nlm005_v1/analysis.json`. Transport families now live in `experiments/results/vision_cifar100_dinov2s_edits_v2/edits.npz` (`test_emb_hflip`, `test_emb_shift1px`; byte-identical to the original NLM-005 file, which was removed as superseded).
- **Void by kill condition 3:** support 129/400 (32%) < 80%. Order gaps non-diagnostic: ST−TS cosine ≤ 0.006 (hflip 0.006 [−0.003, 0.017], shift 0.004 [−0.003, 0.013]); shift1px R_no_coarse 0.027 [−0.003, 0.057] on a sensitivity row. Cosine leads native candidates by ≈0.32 on every order.
- **Lessons.** hflip/1-px shift are augmentations DINOv2 was trained to be invariant to, so they are near-identity moves in its world — transports must lie outside the trained invariance class. 40 random candidates over 100 classes cannot reach 80% support — candidate sampling must be stratified.

## NLM-003 v2 diagnostics — R's win was a coarse-head leak (2026-08-27)

- **Design.** Same lock, artifact, endpoint as NLM-003; new anchor sample; audit #2 diagnostics (tie accounting, R without coarse head, cheap-baseline ladder,

kNN k-sensitivity). Ledger `nlm003_v2_diagnostics` (Round 9: sensitivity accounting, not new evidence); artifact `experiments/results/nlm003_v2_diagnostics/analysis.json`.

- **Leak.** `R_no_coarse` 0.586 < `F` 0.667 (R with coarse 0.762; fine labels nest inside coarse classes). The NLM-003 R-over-F directional claim is withdrawn. Δ_{F−R} on this resample −0.095 [−0.142, −0.049]. R ties on 22–33% of comparisons.
- **Ladder.** cosine 0.934, PCA-32 cosine 0.941, Euclid 0.933; pixel-stat Euclid 0.624, raw-pixel cosine 0.622. kNN same-class flicker 0.18/0.13/0.10 vs cross-class 0.41/0.38/0.37 at k = 8/32/128 — world-path contrast robust to k.

## NLM-004 — random-init null world; SUPPORTED (2026-08-27)

- **Design.** Preregistered in ledger (`nlm004_prereg_null_world`) before scoring: random-init DINOv2-small chart (`experiments/results/vision_cifar100_randinit/`), true fine-label endpoint. Ledger `nlm004_v1_null_world`; adjudication `nlm004_round9_adjudication` (supported, exploratory — bootstrap CIs not in artifact); artifact `experiments/results/nlm004_v1/analysis.json`. CPU, 230 s.
- **Supported.** Cosine 0.575 in the null chart vs 0.946 trained (gap 0.371; gates ≤ 0.70 and ≥ 0.20). Embedding-kNN fine accuracy 0.069 vs 0.761. Same-class chart-line kNN flicker 95% (null) vs 12.7% (trained). Semantic heads collapse (coarse 0.21) while pixel-statistic heads stay strong (rgb 0.83, luma 0.82) — cheap-baseline confound noted.
- **Reading.** The chart's task-effective metric and affine-path smoothness are created by training in this encoder/dataset; the null chart has neither.

## NLM-003 — R beats F on the true fine-label endpoint; cosine dominates both (2026-08-27) — R-over-F WITHDRAWN (see v2 diagnostics)

- **Design.** Locked at `e2a1fb2` (`theory/EXPERIMENTS.md`, NLM-003). Same frozen CIFAR-100/DINOv2-small artifact and runner as NLM-002, endpoint switched to the true fine label (no head is trained on it):
`python experiments/run_nlm002_vision.py --cache experiments/results/vision_cifar100_dinov2s --out nlm003_v1 --endpoint fine_label`.
Ledger `nlm003_v1_true_fine_endpoint`; artifact `experiments/results/nlm003_v1/analysis.json`.
- **Directional gate met.** Profile-continuity `R` 0.734 vs Fisher pullback `F` 0.630, Δ_{F−R} = −0.104 [−0.148, −0.058] over 6,199 scored pairs; support thin (130/400 anchors had a same-fine-class candidate among 40 draws).
- **Chart metrics dominate.** Cosine 0.946 and Euclidean 0.935 on the same anchors beat both native constructs by 20–30pp.
- **Tier-3 audit #2 reclassification (adopted).** NLM-003 is a **narrow instrument comparison** — "these implementations lose to cosine on this endpoint" — not evidence that native geometry is generally dominated (one encoder, one endpoint, one-step random substitutions, one seed, 130 supported anchors). `R` takes five values with 0.5 tie credit and includes the coarse head (fine nested in coarse), so tie accounting and an `R`-without-coarse

rerun are required. Next gate: random-init null (NLM-004, `nlm004_prereg_null_world`), cheap-baseline ladder, kNN k-sensitivity, nonlinear re-charting, composed / out-of-distribution moves.

## NLM-002 — non-LM branch (CIFAR-100/DINOv2): endpoint killed, chart-path structure found (2026-08-27)

- **Design.** CIFAR-100 → DINOv2-small CLS, 6000 train / 2000 test, raw pixels stored (`experiments/results/vision_cifar100_dinov2s/`, built by `experiments/build_vision_cache.py`). Runner `experiments/run_nlm002_vision.py` (default endpoint `rawpixel_knn`). Ledger `nlm002_v1_nonlm_branch`; artifact `experiments/results/nlm002_v1/analysis.json`. CPU, 133 s.
- **M2 kill condition met.** Raw-pixel k=32 kNN fine label is nearly uninformative (0.115 accuracy; 0.12 agreement with embedding kNN, which scores 0.761), so the locked endpoint is invalid and M3 (`F` 0.601 vs `R` 0.605, Δ = −0.004 [−0.034, +0.026], 16,660 pairs) is a tie on noise, not a primitive verdict. Lesson: an endpoint must be independent of both candidates *and* informative — the true fine label is both (→ NLM-003).
- **M1 chart-path structure (informative, audit-qualified).** Along straight lines between same-class embeddings the coarse-semantic readout flickers on only 2% of paths; between classes the fine-label kNN flickers on 38% and any-readout on 78%. Audit #2: the 2% figure is weak evidence (affine argmax is near-monotone by construction) and kNN flicker is at k=32 only — a k-sensitivity analysis is required before any world-path claim. Pixel-stat heads are weak (52–59% test acc), so their 21–24% flicker is partly head noise.
- **Implementation decisions flagged at lock:** pixel statistics of interpolated points are approximated (no pixels exist off the data), and the fine-label head is never trained.

## NLM-001 — verdict: negative on predictive novelty (2026-08-27)

- **Design.** Analysis-preregistered at `fea3a8f` over sequestered raw matrices (`experiments/results/nlm001_v1/manifest.json`); three CPU systems (Qwen3-0.6B, gemma-3-270m, SmolLM2-360M); primary = 72 calibration-unseen words, all 80 as sensitivity; `--rule pooled --scale-normalize`. Command and metrics: ledger `nlm001_v1_primary_72`; artifacts `experiments/results/nlm001_v1/analysis_primary_72.json`, `analysis_sensitivity_80.json`.
- **Central bet fails.** Native calibration-KL closeness does not beat a learned diagonal Mahalanobis metric on the model's own contextual hidden states for held-out orderings: Qwen Δ = −0.058 [−0.222, +0.034]; gemma Δ = +0.017 [−0.02, +0.06]. Every predictor scores 0.95–1.00 — the robust held-out labels are large-gap easy pairs (instrument limitation). Post-verdict reading (ledger `nlm001_v1_postverdict_note`): unlearned centered contextual cosine at layer 14 reaches 1.000 vs native 0.954, and the preregistered selection rule chose an overfit metric (calib 1.000, held-out 0.947), so the reported Δ understates the native loss.
- **Context reversals exceed the paraphrase null** in Qwen (Q = 2.12

[1.70, 2.56], R = 0.18) and SmolLM (Q = 17.1 but W ≈ 0.005, so Q is not interpretable there); not in gemma (Q = 1.40 [0.90, 2.55]).

 **Directedness absent.** Robust (≥2-of-4) asymmetric pairs: 1.5% Qwen, 9.2% SmolLM. Cross-system transfer τ_b: 0.14 (qwen|gemma), 0.47 (qwen|smollm), 0.14 (gemma|smollm).

 **Kill conditions 3 (predictive novelty), 6 (coordinate confound), 8 (instrument metadata recorded post hoc) apply.** Tier-3 fresh audit adopted: T2 is geometrically vacuous, κ is an invariant of the probe table not the space, B>W may recover the hand-authored block taxonomy, and no NLM-001 outcome could have earned "cosine is the wrong object".

 **What we learned.** The substitutability/KL primitive on lexical embedding rows adds nothing over a symmetric learned metric on contextual states. Do not run NLM-002 on more words; next is a competition among primitives (see `STATE.md`). Runners must record tokenizer revision, library versions, thread and batch settings at run time.

## NLM-001 — instrument calibration, pre-verdict (2026-08-27)

 **NLM-001 — contextual substitutability, context rank, and transfer.** Frozen theory contract: `theory/EXPERIMENTS.md`. One CPU entrypoint, `experiments/run_lexical_closeness.py` (using the existing substitution-probe helper); frozen slice: `experiments/config/lexical_probe_v1.json`. The 12-word smoke and disclosed eight-item full-pipeline validation are calibration only. The latter invalidated the MAD robustness rule and put asymmetry signs at chance; H1 is exploratory. Primary analysis uses the 72 calibration-unseen words, with all 80 reported only as sensitivity. Three-system raw matrices were acquired concurrently before the Round-2b amendment and stayed sequestered until the amended contract was committed at `fea3a8f`; the verdict entry above is the first outcome analysis. Ledger: `substitution_probe_smoke_qwen3_0p6b`, `nlm001_pipeline_smoke_8`; artifacts `experiments/results/pipeline_smoke_8/`.

S53 follow-up: two-round consumer attribution review and bounded official-repository access check, recorded as `s53_consumer_attribution_access_20260914`. Reference graph queries verify answers, not neural-reader competence. Three matched feature arms are proposed for one late request. Box inspection failed and revision API returned 504; endpoint absence is not inferred. Execution deferred, no new empirical block.

S54: one primary sequential-merging source inspected after two-round direction review. Endpoint order robustness and stage-relative retention are different; classification-only evidence does not establish joint composition. Ledger `s54_admission_order_source_20260914`; zero new empirical blocks or model forwards.

S55: checked historical vision cache directories contain manifests only. A bounded packet search and concept-consumer source check selected no execution. The source measures global policy editing, not the proposed local attribute correction. Ledger `s55_resource_and_editable_interface_20260914`; six local probe blocks and fifteen scored model forwards unchanged. No new runner, package or GPU work.

## BALANCED KILL EXPERIMENT v3 — 2026-09-19

**Purpose:** Operator-balanced cell set (R21/R23 mandate) to resolve effective-n limitation of the original 40-cell set, where operator explained 34-74% of fragility variance and effective n ≈ 6 strata.

**Design (Fable-reviewed, R24):**

- 69 cells: 60 primary (+: 15, -: 15, //: 15, %: 15) + 9 appendix (*: 6, **: 3)
- ALL operands 1-9 (no double-digit tokenization confound)
- Identity filter: "answer readable without an arithmetic step" — zero identities
- 24 perturbations (groups A-D, same as original 40-cell), 2 surfaces
- 3312 forward passes per model, fp32 CPU
- Pre-registered: primary 60-cell core for main analysis; 69-cell full and residual-after-stratum-means as secondary views
- Power ~0.72 for rho=0.3 at n=69

**Models:** (same panel as original + Qwen3-0.6B-Base per R23 C1)
Qwen3-1.7B-Base, SmolLM2-1.7B, SmolLM2-1.7B-Instruct, SmolLM2-360M, SmolLM2-135M, Qwen3-0.6B-Base, Qwen3-0.6B-Instruct, Qwen3-1.7B-Instruct, StableLM-2-1.6B, CodeGen-350M, Phi-1.5

**Key questions:**
1. Does the gap survive with operator-balanced cells?
2. Does residual gap (after stratum means) match raw gap?
3. Does cross-model fragility transfer change from -0.022?
4. Does eta² for operator drop from 34-74%?

**Runner:** `experiments/run_balanced_kill.py`

**Results:** `experiments/results/transfer_spectrum/balanced_kill_*.json`

**Ledger:** `trho_balanced_kill_v3_launch`

**Results (5 models complete, StableLM running):**

| Model | Acc | Gap | CI | ResGap | eta2_op | Admissible |
|---|---|---|---|---|---|---|
| Qwen3-1.7B-Base | 99.1% | 0.500 | [0.411, 0.588] | 0.462 | 0.394 | Yes |
| Qwen3-0.6B-Base | 97.2% | 0.271 | [0.187, 0.354] | 0.427 | 0.653 | Yes |
| SmolLM2-1.7B | 87.6% | 0.275 | [0.202, 0.362] | 0.389 | 0.687 | Yes |
| SmolLM2-360M | 69.2% | 0.244 | [0.186, 0.312] | 0.471 | 0.854 | NO |
| Phi-1.5 | 65.0% | 0.034 | [0.006, 0.067] | 0.190 | 0.834 | NO |
| StableLM-2-1.6B | 72.0% | 0.215 | [0.161, 0.285] | 0.173 | 0.608 | NO |

**6-model cross-analysis — R26 REVIEW COMPLETE, MAJOR RETRACTION:**

~~TWO-CLUSTER STRUCTURE~~ **RETRACTED (R26).** The "two clusters" were a group-ordering artifact: Qwen3 has D>A mean distance, all 4 non-Qwen3 have D<A. This single bit reproduces the partition. Group-mean-only null gives HIGHER rho for non-Qwen pairs.
Within-group pert ranks (group ordering removed): SmolLM2 within collapses +0.739 -> +0.014; SmolLM2-StableLM +0.642 -> +0.129; Phi-StableLM +0.457 -> -0.029.
BUT Qwen3-Phi RISES +0.253 -> +0.614. Qwen3 within-family SURVIVES: +0.943.

**LEVEL-OF-ANALYSIS DISSOCIATION (R26 key finding):**

- Pert-level rho: Qwen3 within = +0.937. Cell-level rho: Qwen3 within = **+0.015 (p=0.90)**.
- Models agree on which perturbation types are damaging but NOT which cells are vulnerable.

- SmolLM2 within-family: pert +0.739, cell +0.496 (moderate agreement at both levels).
- S1.7-Phi: pert +0.543, cell **-0.576** (anti-correlated at cell level!).
- Split-half cell reliability 0.76-0.98 (real signal, not noise).

~~Admissible-only gap~~ **RETRACTED (R26).** n=1 within pair, n=2 cross pairs — no power.
Cell-level rho was zero WITHIN Qwen3 anyway. The gap is perturbation-magnitude ordering.

~~H1 (accuracy vs eta2_op)~~ **NOT ESTABLISHED.** rho=-0.771, p=0.072, n=6.
Without Phi (p_digit=0.0004): p=0.19. eta2 driven by per-op accuracy dispersion.

**Confound tests:**

- TOKENIZER: REFUTED for SmolLM2/StableLM/Phi. NEW: Qwen3 c_newline_before merges `\n\n` into one token. Qwen3-0.6B's single largest pert. Without it, C>A drops.
- OPERAND MAGNITUDE: REFUTED — cell residuals uncorrelated with max(a,b)
- GROUP C POSITION: CONFIRMED — relabeled as prefix-position inert
- GROUP ORDERING: CONFIRMED (R26) — the dominant confound in all cross-model pert rhos

**~~Surviving after R26~~ — FURTHER RETRACTED BY R27:**

**R27 ADVERSARIAL REVIEW — GAP IS D-COLUMN RELIABILITY ARTIFACT:**

- ~~"Gap real for all 6 models"~~ → Phi fails permutation test (p=0.31). Q0.6/StLM marginal.
- ~~"A-D gap measures inert vs semantic"~~ → AB=AA in 5/6 models (B identical to A). A not special.
- ~~"D perturbations shift cell vulnerability"~~ → Disattenuated AD = 0.94-0.98 for S1.7/S360/Phi/StLM. Only Qwen3 genuine (0.82).
- DD reliability (within-group rho): Q1.7=0.134, Q0.6=0.392, S1.7=0.531, Phi=0.824. D columns are unreliable; AA-AD gap = reliability artifact.
- The measured d[cell,pert] IS header sensitivity (logit distance with vs without `# Python code\n`).

**Surviving after R27:**

- Qwen3 within-group pert rho = +0.893 (robust under all analysis variants)
- Reliable-within/absent-across cell dissociation (split-half 0.85-0.95, cross ≈ 0)
- Fragile ~0.5 cross-family pert cluster (Qwen3↔Phi/StLM; dies under exclusions)
- Qwen3-only genuine cell-ranking shift (disattenuated AD = 0.82, CI excludes 1)
- IT > scale for SmolLM2 pert ordering (base↔instruct +0.624 vs base↔360M +0.157)

**SmolLM2-1.7B-Instruct COMPLETE (7th model, 4th admissible):**

| Model | Acc | Gap | CI | ResGap | eta2_op | Admissible |
|---|---|---|---|---|---|---|
| SmolLM2-1.7B-Instruct | 93.4% | 0.307 | [0.231, 0.397] | 0.452 | 0.500 | Yes |

IT comparison (SmolLM2-1.7B): acc 87.6%→93.4%, gap 0.275→0.307, eta2_op 0.687→0.500.
Base↔Instruct: pert-beyond-group rho +0.624 (p=0.001), cell-beyond-op +0.572 (p<0.001).

**Status:** 7/10 models complete. R27 demolished the gap as a semantic measure. 2×2
D-reliability diagnostic RUNNING on Qwen3-0.6B to determine if D unreliability is
structured (semantic) or token noise.

(33) **R27 2×2 D-reliability diagnostic — Qwen3-0.6B (2026-09-20).** DONE.
3312 forward passes, 364s CPU, 69 cells × 24 perts × 2 surfaces.
Result: D unreliability is STRUCTURED (5/6 ops have within-op rho 0.65-0.89). ADJACENCY
is the driver: O-O (+0.660) ≈ A-A (+0.696), both >> D-D (+0.392). temp_var is token noise.
Data: `experiments/results/transfer_spectrum/r27_2x2_qwen3_0.6b_base.json`

(34) **R27 2×2 D-reliability diagnostic — SmolLM2-360M replication (2026-09-20).** DONE.
3312 forward passes, 237s CPU, 69 cells × 24 perts × 2 surfaces. Accuracy: 55.9% (caveat).
**ADJACENCY REPLICATES:** O-O (+0.609) >> D-D (+0.412). All 6 ops structured (within-op 0.82-0.98).

**NUANCE:** In 360M, O is BETWEEN A and D (not ≈ A like Qwen3). A-O (0.409) < A-D (0.536) — own-line ops probe different patterns from inert despite higher reliability. Adjacency affects reliability universally but pattern identity is model-specific. temp_var (+0.821) is structured in 360M vs anti-correlated in Qwen3 (-0.346).
Data: `experiments/results/transfer_spectrum/r27_2x2_smollm2_360m.json`

(35) **Answer identity confound test (4 models × 2 surfaces, 2026-09-20).** DONE → RETRACTION. No new forward passes (reanalysis of isomorphic same-family data). D-D ≤ E-E-same-sign in ALL 8 tests. Isomorphic meaning effect RETRACTED — fully explained by answer identity confound. Sign matching is the dominant correlation factor ($R^2$ increment 0.183). Meaning adds $R^2 = 0.003$. See NOTEBOOK entry 62h-62i.
**R29 CORRECTION:** The 62h comparison was biased (D-D averaged cross-sign pairs, EE only same-sign). Corrected DDsame vs EEsame: SmolLM2-1.7B +0.105 [0.025, 0.199] FL, +0.231 [0.116, 0.350] 11b (both excl 0). Meaning is small+model-dependent, not zero.

(36) **R29 adversarial review (2026-09-20).** Corrections to entries 62h/62i/adjacency. Key findings: (1) meaning retraction overclaimed; (2) adjacency confounded with locus; (3) disattenuated AD not D-specific; (4) 62i regression non-identifiable; (5) Phi failure is inadmissible data. See NOTEBOOK entry 67.

(37) **R29 inside-line inert experiment — Qwen3-0.6B (2026-09-20).** DONE → DECISIVE. 4140 forward passes, 69 cells × 30 perts × 2 surfaces. Adds group I (in-line inerts: `x = e # c`, `x = e;`, `x = e ;`, `x = e `, `x = e\t`, `x = e`) alongside A/D/V/O. Tests whether D unreliability = adjacency-to-expression or locus (in-line vs after-line).
**RESULT:** I-I = +0.708, A-A = +0.696 → line position effect +0.012 (ZERO). D-D = +0.392, O-O = +0.660. A-I cross = +0.728. Expression modification effect = -0.316. ADJACENCY-TO-EXPRESSION CONFIRMED, LOCUS HYPOTHESIS REFUTED. Per-pert: 5/6 I perts reliable (0.757-0.799); anomaly: i_trail_space = 0.367. D-V structuredness replicates R27.
Data: `experiments/results/transfer_spectrum/r29_inline_inert_qwen3_0.6b_base.json`

(38) **R29 inline-inert SmolLM2-360M replication (2026-09-20).** DONE → REPLICATES. 4140 forward passes, 69 cells × 30 perts × 2 surfaces. Accuracy: 57.6% (below 80% caveat). I-I = +0.814, A-A = +0.780, D-D = +0.412. Line position effect: +0.034 (near zero). Corrected (excl i_trail_space/a_whitespace duplicate): A-A = +0.746, I-I = +0.789, diff = +0.044. i_trail_space NOT anomalous in 360M (0.863 vs Qwen3's 0.367) — model-specific token sensitivity.
Data: `experiments/results/transfer_spectrum/r29_inline_inert_smollm2_360m.json`

(39) **R30 adversarial review of inline-inert (2026-09-20).** PROVISIONAL verdict. 15 concerns, 4 SERIOUS: (1) duplicate pert found (i_trail_space = a_whitespace), (2) inert token reproduces D-sized drop → expression modification NOT necessary, only sufficient, (5) I perts don't touch operand span → adjacency vs semantics still confounded, (10) I group selection bias toward safe edits. Key recommendations: in-expression inerts, larger pert groups, whitespace-token census. See NOTEBOOK entry 69.

(40) **R30b in-expression inert — Qwen3-0.6B-Base (2026-09-20).** DONE → CORRECTED post-Fable review. 69 cells × 36 perts × 2 surfaces, 1031s wall, 89.4% accuracy.
6 groups: A (after-line inert), I (in-line inert outside expression), J (in-expression inert — NEW), D (in-line semantic), V (lexical variants of D), O (own-line semantic).
Pooled J-J = +0.413, but 3 SERIOUS defects found by Fable adversarial review: (1) `//`-comment artifact on 15 cells dominates pooled rho (10x distance inflation),

(2) j_spaces_both is pseudo-replicate of j_space_before_op (rho 0.957),
(3) j_unary_first misclassified (adds AST node, belongs in D).
**Op-stratified (correct): J-J = 0.53-0.59 vs I-I = 0.87, D-D = 0.29. J is INTERMEDIATE.**
Neither adjacency nor semantic change predicts the ordering; "rarity fits" WITHDRAWN
post-R31 Fable review (pooling artifact — op-stratified loadings flat at 0.53-0.60
despite 3x surprisal range). NEW FINDING: `a // b` read as C-comment on bare surface;
header restores floor division (surface disambiguates language, 10x effect). See NOTEBOOK 73.

(41) **R30b replication — SmolLM2-360M (2026-09-20).** DONE → UNRELIABLE (accuracy below threshold).
69 cells × 36 perts × 2 surfaces, 55.96% accuracy (below 80% threshold).
A-A=+0.669, I-I=+0.812, J-J=+0.621, D-D=+0.412. J-J > midpoint(A,D)=0.540,
consistent with J intermediate/inert-leaning. Not used as evidence — accuracy too low.
Fable review correctly warned against replicating this design. See NOTEBOOK 74.

(42) **R30b within/between decomposition — Stage 0 (2026-09-20).** DONE — ZERO COST.
Computed strat4 (op-stratified A-loading), betwOp (between-operator block correlation),
per-operator loadings with 10000-sample bootstrap CIs for all 36 R30b perts.
Saved: experiments/results/transfer_spectrum/r30b_decomposition.json.
Three-level plateau confirmed: A/I strat4 0.79-0.95, J 0.50-0.87, D/V -0.01 to 0.66.
j_space_after_op is outlier at 0.87 (nearly A-level, betwOp=1.00). Revised plateau:
in-expression AST-preserving edits cluster at 0.50-0.66 except space-after-op.
d_temp_var: strat4=-0.007 but betwOp=0.657 (preserves block structure, destroys cell ranking).
d_cond_true: strat4=0.581 but betwOp=0.086 (opposite: preserves cell ranking, destroys block).
See NOTEBOOK 79.

(43) **R31 Stage 1 — 5 new spacing/paren perts (2026-09-20).** DONE. CORRECTED post-Fable review.
69 cells × 7 perts (5 new + 2 anchors) × 3 passes (bare, header, surprisal).
Qwen3-0.6B-Base, fp32 CPU. 226s.
Fable adversarial review: 1/6 claims survive, 5 withdrawn.
SURVIVING: p_double < d_parens, cell-level paired bootstrap diff -0.376 CI[-0.60,-0.15].
WITHDRAWN: per-operator mechanism (within 1 SE), betwOp inversion (p=0.24), token-context
refutation (`%` artifact), rarity dead (untested as registered), CIs wrong (operator-level).
LEADING ALTERNATIVE: header shielding (depth-monotone attenuation). `%`-disambiguation
artifact confirmed. Spacing perts near-inert once artifact excluded. See NOTEBOOK 80.

(44) **R32 Nesting depth test (2026-09-20).** DONE.
69 cells × 2 perts (p_triple + a_empty anchor). Qwen3-0.6B-Base, fp32 CPU. ~30s.
Tests M-shield prediction: does strat4 decrease monotonically with paren depth?
Depth series: expr(0.924) → (expr)(0.655) → ((expr))(0.279) → (((expr)))(0.287).
Result: FLOOR at depth 2 (p_triple ≈ p_double, diff +0.007). NOT monotonic.
Per-operator mean distance: M-shield holds d0→d2 on header-sensitive ops (`-`, `%`),
but ALL 4 operators show small mean distance INCREASE at depth 3.
Tokenization: all depths ≥1 have 8 tokens (` (((` and `)))\n` are single tokens).
See NOTEBOOK 80 (R32 section).

(45) **R33 Zero-cost re-analysis — artifact exclusion + cell-level CIs (2026-09-20).** DONE.
Zero cost (reads saved R30b/R31/R32 data). Implements all Fable review recommendations.
Artifact exclusion rule (median > 3x A-median): catches j_space_before_op/`//`,
j_spaces_both/`//`, s_no_spaces/`%`, s_space_after_only/`%`, d_temp_var/`+,//,%`.

Cell-level stratified bootstrap (2000 iterations) for all 42 forms.
CLEAN LANDSCAPE: spacing perts near-inert (0.66-0.80), single-paren forms 0.58-0.66,
double/triple parens uniquely at 0.28. "Three-level plateau" was artifact of
disambiguation inflation. Paired contrasts confirmed. See NOTEBOOK 81.

(46) **R33b H_rarity as registered — 13-form test (2026-09-20).** DONE — INCONCLUSIVE.
69 cells × 8 R30b forms × 1 forward pass = 552 forward passes, 63s CPU.
Computed line surprisal for 8 R30b in-expression forms + 5 R31 forms = 13 total.
Saved: experiments/results/transfer_spectrum/r33b_r30b_surprisal.json.
H_RARITY (13 forms, raw Spearman): rho=-0.196, p=0.522. NOT SIGNIFICANT.
Partial on |token delta|: rho=-0.151. Registered threshold (rho ≤ -0.6, CI excl 0) FAILS.
Sign correct (higher surprisal → lower strat4) but effect weak and underpowered at n=13.
See NOTEBOOK 82.

(47) **Fable R34 design review — R34 ABANDONED (2026-09-20).**
Review of proposed M-shield test. Verdict: DO NOT RUN AS DESIGNED.
Key finding from existing C-group data: "Python evidence" is NOT the operative variable.
`pass` (Python keyword) RAISES header distance by 50%; `# start` (comment) COLLAPSES it.
Prefix effect tracks "first-line-is-a-comment", not P(Python|prefix).
Paren floor (~14) is 3× ABOVE comment-prefix floor (~4) — M-shield prediction fails.
p_double is genuinely REORDERED (Pearson vs A = 0.105), not "A scaled down."
M-SHIELD AS STATED IS REFUTED by existing C-group data + Pearson check.
RECOMMENDED REPLACEMENT: (a) C-group re-analysis as prefix family, (b) 2×2 factorial,
(c) sign-flip control (`# C code\n`). See NOTEBOOK 83.

# Native latent mathematics — living axioms

## Philosophy and current application (2026-09-13)

The denizen's world remains the enduring philosophy. Identity, moves, effort,
maps and laws should arise from behaviorally meaningful structure, independently
of chosen coordinates. Existing mathematics is welcome; usefulness is the test.
The [current application](CUMULATIVE_CAPABILITY_ACQUISITION.md) is cumulative
capability acquisition across pretrained models. It grounds this philosophy
without exhausting its meaning or changing the status of the theorems below.
Future-response identity, operation preservation and causal substitution are
candidate foundations for acquisition interfaces, not evidence of transfer.

Historical experimental interpretations below must be read with later audit
corrections in [STATE](../STATE.md). In particular, the Falcon SVB grounding
paragraph predates the documented cache-continuation defect and does not establish
settling or native access cost; see [runtime correction](../docs/HANDOFFS.md).

## Navigation requirements (what must exist before theorem)

A denizen must first define:

1. identity — when a moved trajectory has returned to the same place;
2. moves — what interventions the world permits (substitution, transport by the world dynamics, composition);
3. cost — operational effort to execute a legal move;
4. map — prediction of consequences of moves not yet made;
5. laws — stable regularities across regions that are reusable for new moves.

For each requirement, the native target and the imported $\mathbb{R}^n$ construct it must beat:

- identity: native relation $x \sim_c y$ from probe agreement for a fixed probe context $c$; imported: neighborhood/equivalence from vector distance; separation: probe-swap swapback vs path-reversal tests with fixed anchors.
- moves: native interventions are those generated by lawful transport and substitution:

$$
\mathcal M = \{m_{\text{sub}}(x,y),\,T(x),\,m_2\circ m_1: m_1,m_2\in\mathcal M\},
$$

where $T$ is one-step dynamics transport and $m_{\text{sub}}(x,y)$ is a substitution permitted by probe constraints.
Imported: linear arithmetic and Euclidean segments. Separation:
$x_t=(1-t)x+t x'$ is not a primitive; it is a **chart-path hypothesis** tested by transport commutation and consequence monotonicity.

Formal world-path predicate (Round 7):

$$
\mathrm{WP}_{h,U}(i,j)=1 \iff (i,j\in\mathcal S_U)\land [\sum_{t=1}^{8} I\{h(y_t) != h(y_{t-1})\}\le 1],
$$

A pair passes only when same-class holds and is rejected as non-world when cross-class flicker is observed.

Caveat: linear-head argmax on affine readouts is nearly monotone by construction, so coarse-head same-class flicker 2% is treated as weak evidence only.

Therefore the Round 7 world-path test must include a nonlinear readout and report kNN-fine M1 separation (12.7% same-class, 38.0% cross-class); otherwise the predicate is considered trivial.

- cost: native move cost is measured on intervention budget (e.g., number of edits, entropy budget, probe-compute), and can be asymmetric; imported: fixed norms or geodesic length; separation: calibration pairs where asymmetry changes order but distance is symmetric.
- map: native map is a transition model for outcomes of unmade moves; imported: function of coordinates or metric neighborhood expansion. A map earns the native label only if it predicts held-out consequences beyond simple chart metrics on the same endpoint and remains predictive under a declared presentation change. Separation: path-specific endpoint predictions (separatrix/interpolation), nonlinear re-chart tests, and composed/unseen moves where coordinate-only surrogates should fail if they are only convenient charts.
- laws: native laws are invariants of trajectory-plus-probe semantics across regions; imported: algebraic identities and smooth manifolds; separation: transport tests of invariants under admissible move families and probe re-indexing.

Consequential motion is not added as a sixth ontological primitive. It is a required derived predicate on an admissible move, relative to a declared downstream response law and tolerance: a move is consequential when the response law distinguishes its endpoint from the start. Navigation needs this predicate because coordinate displacement and change of navigational consequence can come apart; the primitive is the observational response relation, not “importance” attached to a vector difference.

NLM-001 currently measured only (1), as observation-only substitutability under probe contexts; it did not instantiate moves, costs, maps, or region laws, so it could collapse onto the model's own contextual representation.

Round 8 map consequence: the DINOv2 fine-label result makes cosine and Euclidean the best task-effective maps currently measured for that world, while neither tested native candidate earns replacement status. This changes the map requirement: beating `F` is insufficient; a native map must also beat simple chart metrics or show that their lead survives a declared reparameterization and new move families. Otherwise the result is a useful chart map, not native geometry.

Round 10 map requirement: a move-family test is non-diagnostic when its transports are known or measured to lie inside the encoder's trained invariance class. Candidate support must also be made achievable by a predeclared, stratified design rather than interpreted from an under-supported random draw. Therefore a native-map claim now requires: (i) at least one transport outside the measured invariance class, (ii) held-out endpoint scoring, (iii) explicit support and candidate-stratum accounting, and (iv) a lead over simple chart metrics on the same supported move family. Stratification is a sampling repair, not evidence of semantics.

Status: the navigation requirements remain the program-level target. The future-response foundation below was adopted by mathematics audit #42 after the round-35 repairs and audit-#42 wording/type corrections. Dialogue and rejected formulations stay in `dialogue/`.

### Empirical grounding: SVB-0 + SVB-1 (2026-09-03)

Scope-variable binding experiments on Falcon-H1-1.5B-Instruct (Python lexical scoping, DynamicCache state injection) produced the first empirical contact

with three navigation requirements:

**Moves.** Neutral suffix tokens (processing steps that do not alter the semantic content) constitute a legal move that changes the accessibility of latent information without changing the information itself. This is a recurrent settling move — it does not change the input state z but changes the denizen's ability to read z through response channel c.

**Cost.** The settling time s*(d) — the number of neutral suffix tokens that maximizes scope-binding fidelity σ at structural depth d — defines an empirical native cost function. Measured values: s*(1)=0, s*(2)=1, s*(3)=2, s*(4)=1. This cost is asymmetric (depth-dependent), non-metric (no triangle inequality observed), and has no $\mathbb{R}^n$ analogue (all coordinates of a vector are equally accessible). The gain at the optimal settling point grows with depth: +30% (d2), +57% (d3), +88% (d4).

**Laws.** The depth-dependent settling profile is a stable regularity: it holds across all 3 variables, all 9 outer values, and reproduces exactly between SVB-0 and SVB-1 at depths 1-2. The profile is NOT geometric decay (ratios 0.73, 0.56, 0.82 — phase-transition-like acceleration at d3).

Candidate native law (pending Codex evidence gate): information at structural depth d in a recurrent latent space has access cost C(d) = d + s*(d), where s*(d) > 0 for d ≥ 2 and the effective fidelity σ*(d) = σ(d, s*(d)) decays much more slowly than the raw σ(d, 0).

Evidence: experiments/results/svb_0/result.json, experiments/results/svb_1/result.json.

## Foundation: future-response geometry (ADOPTED by mathematics audit #42 after the round-35 repairs and audit-#42 wording/type corrections; rounds 31-36)

The status of every item is stated explicitly. Definitions D1--D7 replace L1--L4 as the adopted active foundation. Presentation covariance remains a candidate law. No empirical result is promoted to an axiom by this section. Nothing currently proved is genuinely new mathematics. The potentially distinctive contribution is the application-level synthesis of interface governance, presentation transport, finite denizen access, and executable-germ restrictions; no mathematical novelty is claimed for that synthesis here.

Status ledger. D1--D6 are adopted definitions. D7 is an adopted definition; its seminorm statement and uniform first-variation lemma are proved under their displayed assumptions; the compatibility requirement and LM finite-vocabulary specialization (round 43) have been revised per audit #48 (REVISE: proof coefficients corrected, compatibility clause rewritten as curve-based expansion, type annotations and caveats strengthened; headline coefficient and seminorm structure confirmed correct). Theorem 1 and its finite corollary are proved. Proposition 2's affine, Gramian, and chart statements are proved in its explicitly extended setting; the softmax extension is sketched. Open Problem 7 is conjectured; only its displayed conditional inequalities, finite-access sandwich, and affine check are proved under their stated assumptions. C1 and C2 in `theory/EXPERIMENTS.md` were retired unrun in round 37: C1 is a

synthetic-consumer check; C2's query strings and several controls are carried forward, but its entity-by-state factorial coverage is not. C2 was retired by allocation, not by full mathematical subsumption. Mathematics audit #44 adopted the LM mathematical extension and the round-39 finite-access/surgeon-world mathematics after the displayed type corrections. Conjecture 5 remains conjectured, execution remains unqueued, and `native_horizon_v1` is not selected.

### D1. Raw presented transition world — definition

A latent world begins with a set $Z$ of raw presented states and a declared family $\mathcal A$ of primitive legal moves

$$
T_a:Z\to Z.
$$

Let $\mathcal W=\mathcal A^*$ be the free syntactic word monoid, acting by $T_{wa}=T_w\circ T_a$, with $|wa|=|w|+1$. Distinct words may induce the same state map. Assume $C\neq\varnothing$, and declare each $O_c$ as a measurable outcome space. The empty word is legal. The notation $wa$ means: apply $a$ first, then continue with $w$.

All prompt forms, encodings, and stored arrays remain distinct elements of $Z$ until the response theory identifies them. No vector-space, metric, topological, differentiable, or presentation-invariance structure is primitive.

Theorems below assume deterministic total moves. A partial move must either be restricted to a common declared domain or totalized by an observable absorbing failure state.

### D2. Denizen-accessible response laws — definition

For each response channel $c\in C$, let

$$
r_c:Z\to\mathcal P(O_c)
$$

be the outcome law emitted through a declared interface of the world. Equip $\mathcal P(O_c)$ with a true metric $D_c$, normalized so that $0\leq D_c\leq1$. Total variation and normalized square-root Jensen--Shannon distance are admissible; KL divergence is not a metric.

Fix the emitted-observation interface before hidden-state inspection. Primitive responses are its declared native output laws; every derived response must factor through them by a fixed, state-independent Markov kernel. A hidden-state decoder does not so factor. Adding its output to the interface defines a different registered world. In a language model, the full next-token law at a declared query position is primitive; grouping its token probabilities into declared outcome classes by a fixed Markov kernel is derived. Equality of the full native laws is preserved by every such derived

response. This criterion is registration-relative and does not itself certify denizen accessibility. Interface admissibility requires an independently fixed architectural or capability boundary.

### D3. Immediate response discrepancy and legal futures — definition

Define immediate response discrepancy by

$$
\rho(x,y)=\sup_{c\in C}D_c(r_c(x),r_c(y)).
$$

For $w\in\mathcal W$, $wx$ denotes the state reached by executing $w$ from $x$. The empty word is included, so present responses are among the future responses.

### D4. Future-response pseudometrics — definition

The foundational future-response distance is

$$
d_\infty(x,y)
=
\sup_{\substack{w\in\mathcal W\\c\in C}}
D_c(r_c(wx),r_c(wy))
=
\sup_{w\in\mathcal W}\rho(wx,wy).
$$

Two auxiliary approximants are

$$
d_h(x,y)
=
\sup_{\substack{|w|\leq h\\c\in C}}
D_c(r_c(wx),r_c(wy))
$$

and, for $0<\gamma<1$,

$$
d_\gamma(x,y)
=
\sup_{\substack{w\in\mathcal W\\c\in C}}
\gamma^{|w|}D_c(r_c(wx),r_c(wy)).
$$

The undiscounted $d_\infty$ is foundational. A horizon or discount is an additional resource convention unless supplied by the world. Finite resources can limit both response resolution and executable word length.

### D5. Operational identity, place, and resolution — definition

Future observational identity is

$$

x\sim y

\iff

d_\infty(x,y)=0.

\]

An exact operational place is an equivalence class in

\[

Q=Z/{\sim}.

\]

The quotient distance is

\[

\bar d([x],[y])=d_\infty(x,y).

\]

At finite resolution \(\varepsilon>0\), the available neighborhoods are the balls

\[

B_\varepsilon(x)=\{y:d_\infty(x,y)<\varepsilon\}.

\]

The threshold relation \(d_\infty(x,y)<\varepsilon\) is not assumed transitive and does not define an exact quotient.

### D6. Maps, laws, presentation candidates, and cost — definition

For a legal move \(a\), its operational map is the descended map

\[

\bar T_a:Q\to Q,

\qquad

[x]\mapsto[T_ax],

\]

whose existence follows from Theorem 1.

A native law is an equality, inequality, or compositional relation among descended maps that predicts denizen-accessible response consequences.

A syntactically specified rewrite \(g:Z\to Z\) may be registered with fixed, state-independent transport data:

- a channel map \(\pi_C^g:C\to C\);
- an action-name map \(\pi_{\mathcal A}^g:\mathcal A\to\mathcal A\), with \(\pi_A^g:\mathcal W\to\mathcal W\) its unique free-monoid extension: \(\pi_A^g(\epsilon)=\epsilon\) and \(\pi_A^g(a_1\cdots a_k)=\pi_{\mathcal A}^g(a_1)\cdots\pi_{\mathcal A}^g(a_k)\); and
- measurable outcome maps \(\tau_{g,c}:O_c\to O_{\pi_C^g(c)}\) whose pushforwards preserve the declared metrics:

\[

$$
D_{\pi_C^g(c)}\bigl((\tau_{g,c})_*\mu,(\tau_{g,c})_*\nu\bigr)
=D_c(\mu,\nu).
$$

The transported future-response discrepancy is

$$
d_\infty^g(x,gx)
=
\sup_{\substack{w\in\mathcal W\\c\in C}}
D_{\pi_C^g(c)}
\bigl((\tau_{g,c})_*r_c(T_wx),
r_{\pi_C^g(c)}(T_{\pi_A^g(w)}gx)\bigr).
$$

For the identity rewrite all three transports are identities. For composable rewrites $g,h$, registration requires

$$
\pi_C^{h\circ g}=\pi_C^h\circ\pi_C^g,
\qquad
\pi_A^{h\circ g}=\pi_A^h\circ\pi_A^g,
\qquad
\tau_{h\circ g,c}
=\tau_{h,\pi_C^g(c)}\circ\tau_{g,c}.
$$

These identity and composition laws prevent state- or word-dependent realignment after outcomes are seen. The rewrite is observationally passive on $S\subseteq Z$ exactly when $d_\infty^g(x,gx)=0$ for every $x\in S$. Passivity is a tested property, not an axiom. A behaviorally consequential rewrite is a legal move only when it is included in the declared action family.

The distance $d_\infty$ measures future response distinguishability, not effort. Movement cost requires a separate resource assignment to executable programs.

### D7. Local response seminorm — definition; seminorm lemma proved under the stated assumptions

This is additional structure, not part of every latent world. Assume $Z$ is equipped with a specified finite-dimensional $C^1$ manifold structure, or another explicitly named differentiable structure supplying tangent spaces, differentials, and absolutely continuous curves, every relevant $T_w$ and $r_c$ is differentiable at $x$, and each outcome metric has a declared tangent norm $\|\cdot\|_{D_c,r_c(T_wx)}$. For $v\in T_xZ$, define

$$
p_x(v)
=
\sup_{\substack{w\in\mathcal W\\c\in C}}
\left\|D(r_c\circ T_w)_xv\right\|_{D_c,r_c(T_wx)}.
$$

\]

When finite, \(p_x\) is a seminorm because it is a supremum of seminorms. A finite denizen can estimate only a restricted object

\[
p_{x,W_0,C_0}(v)
=
\sup_{\substack{w\in W_0\\c\in C_0}}
\left\|D(r_c\circ T_w)_xv\right\|_{D_c,r_c(T_wx)},
\]

for a finite registered word set \(W_0\subset\mathcal W\) and finite \(C_0\subset C\). The choice \(W_0=\{w:|w|\leq h\}\) is finite only when the primitive action alphabet \(\mathcal A\) is finite. Immediate derivatives alone do not determine the full \(p_x\), because its definition still ranges over all future words.

Once a restricted Jacobian is known, it is a local map: it predicts the first-order response consequence of an unexecuted infinitesimal perturbation. Separately declare parameterized legal-move germs \(\phi_j(t,\cdot)\) with \(\phi_j(0,x)=x\); define \(E_x\) as the specified cone generated by \(\partial_t\phi_j(0,x)\), for example their closed conic hull. Discrete legal moves alone do not determine \(E_x\). The navigational interpretation applies only on \(E_x\subseteq T_xZ\). On arbitrary chart directions outside \(E_x\), \(p_x\) is an instrument-level sensitivity geometry rather than a denizen-usable map.

Uniform first-variation lemma — proved under the displayed condition. Let \(x_t\) be any differentiable curve with \(x_0=x\) and \(\dot x_0=v\), and assume \(p_x(v)<\infty\). If the metric first-order expansions are uniform over \((w,c)\), meaning

\[
\sup_{\substack{w\in\mathcal W\\c\in C}}
\left|
\frac{D_c(r_c(T_wx),r_c(T_wx_t))}{|t|}
-
\left\|D(r_c\circ T_w)_xv\right\|_{D_c,r_c(T_wx)}
\right|
\longrightarrow0,
\]

then

\[
\lim_{t\to0}\frac{d_\infty(x,x_t)}{|t|}=p_x(v).
\]

Indeed, the absolute difference between the two suprema is bounded by the displayed uniform remainder. Pointwise differentiability without this uniformity does not justify exchanging the limit with the infinite supremum.

#### Compatibility requirement (proposed, audit #48 REVISE applied)

When the registered outcome distance $D_c$ admits a first-order expansion along every relevant $C^1$ curve $\eta$ through $y=r_c(T_wx)$,

$$
D_c(y,\eta(t))=|t|\,F_{c,y}(\dot\eta(0))+o(|t|),
$$

where $F_{c,y}$ is curve-independent and is a norm or seminorm on the tangent space at $y$, then D7's tangent norm **must** equal $F_{c,y}$ rather than an independently declared norm. If no such $F_{c,y}$ exists for a given channel $c$, that channel cannot instantiate ordinary D7. Note that D2's $D_c$ is a distance on the response-law space $\mathcal P(O_c)$, not a smooth metric tensor; ordinary distances — including $\sqrt{\mathrm{JS}}$ — are not smooth at the diagonal as two-point functions, so the expansion is taken along curves rather than as a bivariate differential. Branchwise compatibility still does not provide the uniformity over $(w,c)$ required to differentiate $d_\infty$.

#### LM finite-vocabulary specialization — proved under stated assumptions (proposed, audit #48 REVISE applied)

Let $V$ be a finite vocabulary with outcome space $O_c=V$, so that the response-law space is identified with the probability simplex $\mathcal P(V)\cong\Delta^{|V|-1}$. Equip it with the normalized $\sqrt{\mathrm{JS}}$ metric (KL in natural logarithms throughout)

$$
D_{\sqrt{\mathrm{JS}}}(p,q)
=\sqrt{\frac{\mathrm{KL}(p\|m)+\mathrm{KL}(q\|m)}{2\ln2}},
\qquad m=\tfrac12(p+q).
$$

For $\pi$ in the simplex interior ($\pi_a>0$ for all $a\in V$) and a tangent vector $u\in T_\pi\Delta$ (so $\sum_a u_a=0$), the local expansion is

$$
D_{\sqrt{\mathrm{JS}}}(\pi,\pi+tu)
=\frac{|t|}{\sqrt{8\ln2}}\sqrt{g_\pi(u,u)}+o(|t|),
$$

where $g_\pi(u,u)=\sum_{a\in V}u_a^2/\pi_a$ is the Fisher metric at $\pi$. Therefore the compatible D7 seminorm for a language model with strictly positive next-token law is

$$
p_x^{\mathrm{JS}}(v)
=\sup_{\substack{w\in\mathcal W\\c\in C}}
\frac{1}{\sqrt{8\ln2}}\sqrt{g_{\pi_{w,c}}(u_{w,c},u_{w,c})},
$$

where $\pi_{w,c}=r_c(T_wx)$ and $u_{w,c}=D(r_c\circ T_w)_x v$.

*Proof sketch.* Write $m=\pi+\tfrac12tu$ and $f(t)=\mathrm{KL}(\pi\|m)+\mathrm{KL}(\pi+tu\|m)$. Each KL expands as

\(\tfrac{t^2}{8}g_\pi(u,u)+O(t^3)\) for interior \(\pi\), giving
\(f(t)=\tfrac{t^2}{4}g_\pi(u,u)+O(t^3)\). Then
\(D_{\sqrt{\mathrm{JS}}}=\sqrt{f/(2\ln2)}
=|t|\sqrt{g_\pi(u,u)/(8\ln2)}\cdot(1+O(t))
=|t|\sqrt{g_\pi(u,u)}/(\sqrt{8\ln2})+o(|t|)\).

Each branch \((w,c)\mapsto(1/\sqrt{8\ln2})\sqrt{g_{\pi_{w,c}}(u_{w,c},u_{w,c})}\)
is a seminorm in \(v\) (the pullback of an inner-product norm through the linear
differential), so \(p_x^{\mathrm{JS}}\) is a seminorm when finite. Strict
positivity of each individual branch does not by itself imply that the supremum
is finite, uniformly interior, or uniformly differentiable; the construction is
generally a supremum, not an attained maximum.

**Remarks.** (1) For a softmax law \(\pi=\operatorname{softmax}(\ell)\) with
logit perturbation \(\dot\ell\),
\(\dot\pi_a=\pi_a(\dot\ell_a-\mathbb E_\pi\dot\ell_A)\), so
\(g_\pi(\dot\pi,\dot\pi)=\operatorname{Var}_{A\sim\pi}[\dot\ell_A]\); here
\(\dot\ell_A\) is the logit perturbation and the log-probability score is its
centered version. (2) For a Markov grouping kernel \(K\),
\(g_{K\pi}(Ku,Ku)\le g_\pi(u,u)\) (by Jensen on each output bin, with zero-mass
bins excluded), so the full next-token channel locally dominates every fixed
grouping — the differential counterpart of
\(D_{\sqrt{\mathrm{JS}}}(Kp,Kq)\le D_{\sqrt{\mathrm{JS}}}(p,q)\).
(3) Boundary behavior is direction-dependent: if \(\pi_a=0\) for some \(a\), a
perturbation remaining within the positive-support face retains \(O(|t|)\) Fisher
behavior, but a perturbation introducing first-order mass into a previously zero
coordinate scales as \(O(\sqrt{|t|})\), and no finite ordinary tangent norm
exists for that direction. The specialization therefore requires strictly
positive next-token law. (4) A supremum of Fisher pullback norms is generally a
nonsmooth Finsler-type (Minkowski) seminorm, not a single Riemannian Fisher
tensor; the maximum or supremum of ellipsoidal norms need not meet classical
Finsler smoothness requirements. (5) Open Problem 7 remains open: this
specialization does not supply uniform control of unseen branches, quotient
regularity, or executable lifting. (6) Finite vocabulary is essential; infinite
alphabets require summability and interchange-of-limit controls not addressed
here. (7) This specialization requires a separately declared differentiable LM
carrier and differentiable response maps; a prompt-string LM does not
automatically have D7 tangent structure.

#### Audit #36 retrospective — measured restricted instance, not a theorem

Treat the patched block-12 residual as the local presented state and the fixed
remaining forward pass as part of the response law. For each of 24 prompt/name
base states \(x_n\), `reachability_v1` measured the empty-continuation
Jacobian \(J_n\) of an eight-outcome derived response channel: centered first-
token tag logits, equivalently centered log probabilities of those eight
tokens. Each

\[

q_{x_n}(v)=\|J_nv\|_2
\]

is an instrument-level local seminorm of the centered-log-probability coordinate map. It is not identified with D7's native \(p_{x_n}\). It becomes one empty-word component only if that derived observable, a compatible bounded metric/tangent norm, and the direction domain are separately declared.

The registered headline was the scaled shared operator

\[
\bar J=\frac1{24}\sum_{n=1}^{24}0.25\|h_n\|J_n,
\]

not a single-state \(p_x\) and not the average of the 24 seminorms. Its top-mode energy was 0.638 (name-bootstrap 95% CI 0.624--0.652), participation effective rank 2.279 (2.197--2.362), \(\sigma_2/\sigma_1=0.450\), and \(\sigma_3/\sigma_1=0.389\). The audit found per-name median top energy 0.635, median effective rank 2.302, and 0.895 mean-energy coherence; the RMS-stacked name-local object was broader at effective rank 2.754. Thus averaging did not manufacture the several-mode local response, but these statistics do not give the rank or dimension of the full future seminorm.

Eight preselected position controls spanned top energies 0.579--0.731 and effective ranks 1.809--2.664, so the result earned `NO SLOT-SPECIFIC GEOMETRY CONCLUSION`. Four displayed-tag-order controls produced broader spectra, showing presentation sensitivity only for those orders. At one fixed dose, the top three shared directions had median predicted-versus-realized centered-logit cosines 0.995, 0.944, and 0.995, with substantial secondary responses and sign-dependent magnitude and decoded-boundary asymmetries.

Audit #36 therefore licenses a coherent several-mode, restricted local response-differential family under this exact model, prompt, vocabulary, site, layer, and dose. It does not license a two- or three-dimensional capacity, low rank of the global \(p_x\), slot-specific geometry, equivalence to generic positions, dose adequacy, storage, retrieval, an explanation of the earlier two-tag pattern, memory capacity, or advancement of the positive-control staircase. The audit-#36 never-say list in `STATE.md` remains binding.

### Theorem 1. Canonical response geometry and descent — proved

Assume D1--D4, with deterministic total legal moves and bounded true outcome metrics. Then:

1. \(d_\infty\) is a bounded pseudometric on \(Z\).
2. Every legal move is nonexpansive:
\[
d_\infty(T_ax,T_ay)\leq d_\infty(x,y).
\]
3. \(d_\infty\) is the least pseudometric \(p\) such that
\[
\rho(x,y)\leq p(x,y)

\]

and every legal move is nonexpansive for \(p\).

4. Future observational identity is an equivalence relation; \(\bar d\) is a metric on \(Q\); and every legal move induces a nonexpansive map on \(Q\).

5. The truncated distances satisfy

\[
d_h(T_ax,T_ay)\leq d_{h+1}(x,y).
\]

6. The discounted supremum satisfies

\[
d_\gamma(T_ax,T_ay)\leq\gamma^{-1}d_\gamma(x,y),
\]

but

\[
d_\gamma(x,y)=0\iff d_\infty(x,y)=0.
\]

Proof. For fixed \(w,c\), the pullback

\[
(x,y)\mapsto D_c(r_c(wx),r_c(wy))
\]

is a pseudometric. Its supremum is therefore a pseudometric. Continuations after \(a\) correspond to the subset of words \(wa\), proving nonexpansiveness. If \(p\geq\rho\) and all moves are nonexpansive for \(p\), then

\[
\rho(wx,wy)\leq p(wx,wy)\leq p(x,y)
\]

for every word \(w\); taking the supremum gives \(d_\infty\leq p\). The quotient and descent statements follow from the zero kernel. The final two inequalities follow by shifting word length by one. \(\square\)

Coalgebraic reading — standard specialization, not a restatement. Put

\[
R=\prod_{c\in C}\mathcal P(O_c),
\qquad
D_R(u,v)=\sup_{c\in C}D_c(u_c,v_c),
\qquad
r(x)=(r_c(x))_{c\in C}.
\]

Then D1--D3 give the deterministic Moore coalgebra

\[
x\longmapsto\bigl(r(x),(T_ax)_{a\in\mathcal A}\bigr)
\]

for \(F(X)=R\times X^{\mathcal A}\). Its behavior map into the final Moore

coalgebra is

$$
\mathsf{beh}(x)(w)=r(T_wx),
\qquad
\mathsf{beh}:Z\to R^{\mathcal A^*},
$$

Under D1's convention, the final coalgebra has output $f(\epsilon)$ and transition

$$
(\partial_a f)(w)=f(wa).
$$

Consequently

$$
\mathsf{beh}(T_ax)(w)=\mathsf{beh}(x)(wa),
$$

so $\mathsf{beh}$ is a coalgebra morphism, and $d_\infty$ is exactly the pullback of the supremum metric on $R^{\mathcal A^*}$. This remark identifies the standard semantics without replacing the elementary word-and-response formulation: the latter keeps the fixed native interface, finite word access, and the denizen's map problem explicit.

Attribution. Theorem 1 is deterministic Moore-machine/final-coalgebra behavioral-pseudometric mathematics; see Baldan et al., [*Coalgebraic Behavioral Metrics*](https://arxiv.org/abs/1712.07511). [Desharnais et al.](https://www.cs.mcgill.ca/~prakash/Pubs/concur99.pdf), [van Breugel--Worrell](https://www.sciencedirect.com/science/article/pii/S0304397504006711), and [Ferns--Panangaden--Precup](https://arxiv.org/abs/1207.4114) are neighboring probabilistic-transition or MDP metric theories, not sources for this exact deterministic construction.

### Corollary and counterexample 3 - finite carriers have exact finite-horizon response distance; affine continuous carriers need not converge uniformly

Finite clause — proved; restatement of Theorem 1's finite corollary. If $Z\neq\varnothing$ and $Z,\mathcal A,C$ are finite, then $d_h(x,y)=0$ is exactly equality of the horizon-$h$ future-response signatures. The synchronous ordered-pair graph has at most $|Z|^2$ vertices, and every reachable pair has a simple path of length at most $|Z|^2-1$. Consequently

$$
d_{|Z|^2-1}=d_\infty.
$$

Affine clause — counterexample proved. Even for one affine action, $d_h\to d_\infty$ need not converge uniformly on $Z\times Z$. Let $Z=\mathbb R$, let the single action be $T(x)=2x$, and let the response be

$r(x)=\delta_x$. Equip the output laws with the metric $W_1^{d_0}$ induced by $d_0(u,v)=\min(1,|u-v|)$. Then

$$
d_h(x,y)=\min(1,2^h|x-y|),
\qquad
d_\infty(x,y)=1\quad(x\ne y).
$$

Consequently, for every finite $h$,

$$
\sup_{x,y\in Z}\bigl(d_\infty(x,y)-d_h(x,y)\bigr)=1,
$$

and the supremum is not attained. Thus $d_h\to d_\infty$ pointwise but not uniformly on $Z\times Z$.

Language-model scope. For the main LM world, a state is a prompt token sequence. Declared moves such as appending fixed tokens or substituting a declared span are deterministic maps on prompts, while $r_c$ is the distributional next-token law. Theorem 1 therefore covers this LM prompt world exactly. If token sampling itself is declared a move, generation produces a stochastic state transition; that different move family requires a declared lifting to distributions, such as an appropriate Kantorovich construction.

Boundary. If outcome discrepancies are unbounded, $d_\infty$ may be an extended pseudometric. State-dependent legality requires typed common domains or observable failure-state totalization.

### Proposition 2. Linear observability seminorm — proved in the linear case

This proposition temporarily extends D2's bounded setting. Let $Z=V=\mathbb R^n$, let each outcome space be a finite-dimensional normed vector space, and suppose every move and response-location map has the affine form

$$
T_a(x)=A_ax+b_a,
\qquad
\ell_c(x)=W_cx+q_c.
$$

The actual response is the deterministic probability law $r_c(x)=\delta_{\ell_c(x)}$. On probability laws with finite first moment, use the Wasserstein-1 metric induced by the possibly unbounded ground norm, so

$$
D_c(\delta_u,\delta_v)=\|u-v\|_c.
$$

Thus the responses remain Dirac laws, but the outcome metrics need not satisfy D2's normalization $D_c\leq1$. Let

$$

T_w(x)=A_wx+b_w.

\]

For positive weights \(\alpha_w\), define

\[

d_\alpha(x,y)

=

\sup_{w,c}\alpha_w

D_c(r_c(T_wx),r_c(T_wy))

=

\sup_{w,c}\alpha_w

\|\ell_c(T_wx)-\ell_c(T_wy)\|_c

\]

and

\[

p_\alpha(v)

=

\sup_{w,c}

\alpha_w\|W_cA_wv\|_c.

\]

Assume explicitly that this supremum is finite for every \(v\). This holds,

for example, for a finite horizon or a uniformly bounded weighted observable

family. Then

\[

d_\alpha(x,y)=p_\alpha(x-y)

\]

and \(p_\alpha\) is a seminorm. Its null subspace is

\[

K=\bigcap_{w,c}\ker(W_cA_w),

\]

so the exact operational places are the cosets \(x+K\), and the intrinsic

linear response geometry is the normed quotient \(V/K\).

After choosing an ambient inner product, define

\[

\mathcal O

=

K^\perp

=

\operatorname{span}_{w,c}

\operatorname{range}(A_w^\top W_c^\top).

\]

For the resulting orthogonal projector \(P_{\mathcal O}\),

\[

p_\alpha(v)=p_\alpha(P_{\mathcal O}v).

\]

The kernel and quotient are intrinsic; the orthogonal projector is not.

For the next construction only, assume that \(\mathcal W\times C\) is countable and equip every response outcome vector space used below with a fixed Euclidean inner product, so that \(\|\cdot\|_2\), adjoints, and \(W_c^\top W_c\) are defined. For weights \(\beta_{w,c}>0\) such that the displayed series converges for every \(v\), define the weighted \(\ell_2\) aggregation

\[
p_2(v)^2
=
\sum_{w,c}\beta_{w,c}^2
\|W_cA_wv\|_2^2
=
v^\top Gv,
\]

where

\[
G
=
\sum_{w,c}
\beta_{w,c}^2
A_w^\top W_c^\top W_cA_w.
\]

Thus the \(\ell_2\) aggregation gives a Hilbert seminorm. The supremum aggregation generally gives an arbitrary seminorm.

Proof. Affine offsets cancel under a shared word:

\[
\ell_c(T_wx)-\ell_c(T_wy)=W_cA_w(x-y).
\]

The supremum of seminorms is a seminorm when finite. Its zero set is exactly the displayed intersection of kernels. The Gramian identity follows by expanding the convergent sum. \(\square\)

Attribution. This is switched/semigroup linear observability because the observable family ranges over arbitrary products \(A_w\), rather than only powers of one state matrix as in [single-\(A\) Kalman observability](https://people.duke.edu/~hpgavin/SystemID/References/Kalman-JSIAM-1963.pdf); see also the [switched-system observability literature](https://homepages.laas.fr/atanwani/bibentries/2013_tac.html).

Chart boundary — proved. The Gramian seminorm agrees up to scale with the Euclidean quotient seminorm \(v\mapsto\|P_{\mathcal O}v\|_2\) exactly when

\[
G=\lambda P_{\mathcal O},\qquad \lambda>0,
\]

\]

in that chart. It agrees with the ambient Euclidean norm on all of \(V\) up to scale exactly when \(K=\{0\}\) and \(G=\lambda I\). A chart that merely separates \(\mathcal O\) from \(K\) is insufficient. Cosine agrees with Euclidean ordering only after normalization and the corresponding isotropy conditions.

Softmax extension — sketched. If

\[
r_c(x)=\operatorname{softmax}(W_cx+q_c),
\]

the global future-response metric is generally not translation-invariant and therefore is not a seminorm of \(x-y\). If the metric first-order expansions are uniform over \((w,c)\), then for every differentiable curve \(x_t\) with \(\dot x_0=v\),

\[
\lim_{t\to0}\frac{d_\infty(x,x_t)}{|t|}=p_x(v).
\]

Without this uniformity, \(p_x\) is only the supremum of the individual pullback tangent seminorms; equality with the first variation of \(d_\infty\) is not claimed. Under the uniform condition this is a Finsler-type local geometry. Global lower comparison with the linear seminorm fails under logit-shift gauge and saturation. Non-affine moves make the differential observability family depend on the entire orbit from \(x\).

### Open problem 7. Directed local-to-global map problem — conjectured program; conditional and affine special cases proved

An executable curve is an absolutely continuous curve \(\gamma:[0,1]\to Z\) with \(\dot\gamma(t)\in E_{\gamma(t)}\) for almost every \(t\) and integrable \(p_{\gamma(t)}(\dot\gamma(t))\). Define the directed extended path distance

\[
\delta_E(x,y)
=
\inf_{\substack{\gamma(0)=x,\ \gamma(1)=y\\
\dot\gamma(t)\in E_{\gamma(t)}\ \mathrm{a.e.}}}
\int_0^1p_{\gamma(t)}(\dot\gamma(t))\,dt,
\]

with the infimum of the empty set equal to \(+\infty\). If the germs are reversible, so \(E_x=-E_x\), then reversing an executable curve is executable and \(\delta_E\) is symmetric. Otherwise \(\delta_E\) is generally a directed extended path distance, not a metric. It descends to a genuine metric on the reachable part of \(Q\) only after its zero kernel and two-way reachability are checked.

**Conjecture 7 — local-to-global response geometry.** In a latent world whose

future-response quotient is a regular differentiable space, uniform metric differentiation, reversible path-generating move germs, and finite uniform control of unseen response branches should make $\delta_E$ a finite-access upper reconstruction of $\bar d$, with equality when future-response geodesics lift to executable state curves. Assume first that the quotient map $q:Z\to Q$ is differentiable and there are $\bar p$ and $\bar E$ on $Q$ such that

$$
p_x(v)=\bar p_{q(x)}(Dq_xv),
\qquad
Dq_x(E_x)=\bar E_{q(x)}.
$$

From this point, $\delta_E$ on $Q$ denotes the same path formula with $(\bar p,\bar E)$. The precise candidate theorem is:

1. Every executable absolutely continuous curve $\gamma$ is absolutely continuous for $\bar d$, and its $\bar d$-metric derivative satisfies

$$
|\gamma'|_{\bar d}(t)
=\bar p_{\gamma(t)}(\dot\gamma(t))
\quad\text{for almost every }t.
$$

2. The behavior map $\mathsf{beh}:Q\to R^{\mathcal A^*}$ is injective and its image is $L$-quasiconvex in the supremum metric: any two behavior points are joined in the image by a rectifiable path of length at most $L\bar d$.
3. Every such behavior path has an absolutely continuous parametrization with an executable absolutely continuous lift of the same length.

Then

$$
\bar d([x],[y])
\leq
\delta_E([x],[y])
\leq
L\bar d([x],[y]).
$$

For $L=1$, $\delta_E=\bar d$. The first inequality is proved under item 1: the endpoint distance of a $\bar d$-absolutely continuous curve is at most the integral of its metric derivative, which item 1 identifies with its $\bar p$-length. Items 2--3 give an executable absolutely continuous curve of length at most $L\bar d$, proving the second inequality. The absolutely-continuous formulation is used rather than restricting $\delta_E$ to piecewise-$C^1$ curves because a rectifiable quasiconvex path and its executable lift need not be piecewise $C^1$. Reversibility is not needed for either ordered inequality, but it is needed to call the resulting

object an undirected length metric. Without items 2--3, bounded response metrics can saturate and make $d_\infty$ strictly smaller than every integrating path length.

For finite denizen access, let $W_n\subset\mathcal W$ and $C_n\subset C$ be finite registered sets, let $p_x^{(n)}=p_{x,W_n,C_n}$, and let $\delta_E^{(n)}$ be the corresponding path distance. If, on the executable tangent bundle of the quotient,

$$
(1-\varepsilon_n)p_x(v)
\leq p_x^{(n)}(v)
\leq p_x(v),
\qquad
0\leq\varepsilon_n<1,
\quad
\varepsilon_n\downarrow0,
$$

uniformly in $(x,v)$, then integration and infimization give the proved sandwich

$$
(1-\varepsilon_n)\delta_E
\leq\delta_E^{(n)}
\leq\delta_E.
$$

Equivalently,

$$
\delta_E^{(n)}
\leq\delta_E
\leq\frac{\delta_E^{(n)}}{1-\varepsilon_n}.
$$

When $L=1$, this is a finite-access multiplicative sandwich for $\bar d=\delta_E$; without the certified relative tail bound, the restricted path distance need not even upper-bound $\bar d$.

Thus the genuinely open part is not the formal integration step. It is to find denizen-checkable hypotheses or certificates for uniform unseen-branch control, behavior-space quasiconvexity, and executable lifting in a real latent space.

**Affine check — proved, with a counterexample to the unconditional claim.** In Proposition 2's affine world, $p_\alpha$ is constant in $x$. If every straight-line translation is admitted as a reversible executable germ, then define the weighted executable path distance

$$
\delta_{E,\alpha}(x,y)
=
\inf_\gamma\int_0^1p_\alpha(\dot\gamma(t))\,dt,
$$

\]

where the infimum ranges over executable absolutely continuous curves from \(x\) to \(y\). For every such curve,

\[
p_\alpha(y-x)
=p_\alpha\!\left(\int_0^1\dot\gamma(t)\,dt\right)
\leq\int_0^1p_\alpha(\dot\gamma(t))\,dt.
\]

The straight segment attains equality, so \(\delta_{E,\alpha}(x,y)=p_\alpha(y-x)=d_\alpha(x,y)\), and the same statement holds on \(V/K\). This is a claim about the explicitly weighted path distance, not the unweighted \(\delta_E\) above. Likewise the unrestricted path distance of the Gramian seminorm is \(p_2(x-y)\), hence equals the corresponding \(\ell_2\)-aggregated global pseudometric; it need not equal the supremum-based \(d_\infty\) unless \(p_2=p_\infty\).

The discrete affine alphabet alone does not license those curves. Take \(V=\mathbb R\), the finite alphabet \(\mathcal A=\{a\}\) with \(T_a(x)=x\), and the law-valued response \(r(x)=\delta_x\). Give the outcome line the bounded ground metric

\[
d_0(u,v)=\min(1,|u-v|)
\]

and give its probability laws the corresponding Wasserstein-1 metric \(D=W_1^{d_0}\). All words act as the identity and Wasserstein distance between Dirac laws equals their ground distance, so

\[
d_\infty(x,y)
=D(\delta_x,\delta_y)
=\min(1,|x-y|).
\]

Moreover, for every \(v\),

\[
\lim_{t\to0}
\frac{D(\delta_x,\delta_{x+tv})}{|t|}
=
\lim_{t\to0}\frac{\min(1,|tv|)}{|t|}
=|v|,
\]

and every future branch is the same branch, hence \(p_x(v)=|v|\). If no parameterized move germs are declared, then \(E_x=\{0\}\). Every executable absolutely continuous curve has derivative zero almost everywhere and is therefore constant. Thus there is no executable curve from \(x\) to \(y\) for \(x\ne y\), and

$$
\delta_E(x,y)=+\infty\qquad(x\ne y).
$$

Therefore Proposition 2 supplies the local seminorm, not the controllability or reversibility needed for local-to-global equality.

Switched/semigroup observability and Finsler/control geometry contain neighboring special cases; novelty is not claimed. The latent-specific role of the problem is epistemic: those theories commonly start with a supplied transition system, whereas a denizen must construct a usable map of unexecuted futures from finite local access.

## Extension: language-model prompt worlds (ADOPTED by mathematics audit #44 after the displayed type corrections; rounds 37-38; execution not queued)

This extension specializes the adopted foundation to prompt strings and keeps three structures separate: append continuations define future-response places; span substitutions are executable interventions on those places; and the model's emitted next-token law is the only primitive response. No hidden-state probe, residual injection, generated sample, or synthetic consumer enters the definitions below.

### Theorem 4. Finite-memory append worlds have exact finite-horizon response distance — proved under the displayed assumptions

Let $V$ be a token vocabulary and let $\mathcal A_+$ be a declared family of append moves. Each $a\in\mathcal A_+$ appends a fixed nonempty finite token string $\sigma(a)$. Define the execution-order append recursively by $\sigma(\epsilon)=\epsilon$ and $\sigma(wa)=\sigma(a)\sigma(w)$, consistently with D1's $T_{wa}=T_w\circ T_a$. Thus $T_{wx}=x_{\sigma(w)}$. Let $\lambda(w)=|\sigma(w)|$. Write $d_\infty^+$ and $d_h^+$ for D4's distances when only $\mathcal A_+$ is used.

Assume that the registered response interface has memory at most $N\geq1$: for every channel $c$ there is a map $\widehat r_c$ such that

$$
r_c(x)=\widehat r_c(\operatorname{suf}_N(x)),
$$

where $\operatorname{suf}_N$ keeps the final $N$ tokens (or the whole string when it is shorter). Then, for all prompt states $x,y$,

$$
\begin{aligned}
&d_\infty^+(x,y)\\
&=\\
&\sup_{\substack{w\in\mathcal A_+^*\\\lambda(w)\leq N-1}}\sup_{c\in C}D_c(r_c(wx),r_c(wy))\\
&=d_{N-1}^+(x,y).
\end{aligned}
$$

The first equality is the sharper token-budget statement; the second uses only that every primitive append contributes at least one token. If every primitive move appends exactly one token, token budget and D4 word horizon coincide.

Proof. If $\lambda(w)\geq N$, the final $N$ tokens of both $wx$ and $wy$ lie wholly inside the shared appended string $\sigma(w)$. Hence $\operatorname{suf}_N(wx)=\operatorname{suf}_N(wy)$, so every channel discrepancy after $w$ is zero. Removing all such zero terms from D4's supremum leaves exactly the words with $\lambda(w)\leq N-1$. Moreover $|w|\geq N$ implies $\lambda(w)\geq N$, so no word beyond D4 horizon $N-1$ can enlarge the supremum. No finiteness of $Z$ is used. $\square$

If a channel appends its own fixed query suffix $q_c$ before reading the law and $|q_c|<N$, the channel-specific last possibly distinguishing append budget is $N-1-|q_c|$. If $|q_c|\geq N$, that channel is independent of the starting prompt for every continuation and contributes only zero terms, including at the empty continuation. Query tokens must therefore be counted exactly once: either inside $r_c$, or as legal append moves, never both.

Scope and boundary. The theorem is native to a sliding-window architecture or to an explicitly registered left-truncation wrapper. A full-context model whose native interface merely rejects strings longer than $N$ does not satisfy the displayed suffix law on $V^*$. Within D1--D4, its append maps must be totalized by an observable overflow state. A genuinely typed partial-action alternative requires a separately defined typed-word and common-domain distance theory and does not inherit Theorem 4 automatically. Any finite bound then comes from the registered capacity and failure semantics, not from suffix forgetting. Software truncation is part of the registered world, not an unmentioned architectural fact. Corollary and counterexample 3's affine world violates the finite-memory premise; calling it "infinite-memory" is an interpretation, not an additional theorem.

Theorem 4 removes an infinite *depth* tail, but not an exponential *branch* problem. Even with finite $V$, all append strings of token length below $N$ can be far too numerous to enumerate. A small query family computes a restricted lower bound on $d_\infty^+$, not the full distance, unless a separate response-completeness certificate controls the unqueried branches.

### Discrete-map boundary

Prompt strings do not supply the differentiable structure required by D7. Thus $p_x$, $E_x$, and $\delta_E$ are absent rather than automatically zero. If one explicitly equips the prompt set with its discrete zero-dimensional manifold structure, then $T_xZ=E_x=\{0\}$, so $\delta_E(x,y)=+\infty$ for distinct points and $0$ on the diagonal. In either formulation, the differential route in Open Problem 7 is not a denizen-usable map of this prompt world. Its native map is combinatorial: a

finite-depth response tree under append moves, usually compressed to a directed graph after suffix or response equivalences are identified.

### Conjecture 5. One-query discrimination in explicit-legend prompt worlds — conjectured; exact identity clause is definitional

For any append world in which the following minimum exists, define the discrimination horizon

$$
H^+(x,y)=\min\{h\geq 0:d_h^+(x,y)=d_\infty^+(x,y)\}.
$$

Theorem 4 is a sufficient, not necessary, condition for this minimum to be well-defined. The value is relative to the registered primitive append macros: regrouping one query into several primitive moves can change $H^+$. The exact assertion $H^+=1$ means $d_0^+<d_\infty^+=d_1^+$. When $d_\infty^+(x,y)>0$, define the saturation profile

$$
S_h(x,y)=\frac{d_h^+(x,y)}{d_\infty^+(x,y)}.
$$

For $d_\infty^+(x,y)=0$, set $H^+(x,y)=0$ and leave $S_h$ undefined; such a pair is one operational place by D5, not by conjecture.

Conjecture. Fix before inspection a finite alphabet of shared-numeral query macros and an explicit-legend prompt population. For pairs that differ in the state denoted by the declared record span, while the remaining registered factors are matched, a single complete query macro attains the full append-future distance:

$$
H^+(x,y)=1.
$$

For a separately predeclared delayed-route control whose differing fact is not exposed by any one-move query but is exposed by a legal two-move composition,

$$
H^+(x,y)>1,
$$

with $H^+=2$ the proximal positive-control prediction. This is a conjecture about the registered prompt and move families, not about all language-model prompts.

Exact falsifiers are direct. Any later continuation with discrepancy strictly larger than $d_1^+(x,y)$ falsifies $H^+=1$ for that pair. Any one-move word that attains $d_\infty^+$ falsifies $H^+>1$ for a delayed control. A two-move witness with $d_2^+(x,y)>d_1^+(x,y)$ proves $H^+>1$ without enumerating the remaining tree. A positive discrepancy on any finite registered continuation is a witness against exact place identity; agreement

on a finite query family is not evidence that \(d_\infty^+=0\).

For floating-point model laws, native_horizon_v1 must predeclare a replay floor, material effect tolerance, clustered population rule, and an inconclusive band. Exact equality tables remain diagnostics only.

Lay so-what: *How many questions must an inhabitant ask before two records become different places--and can one question really reveal everything that any later question could?*

### D8. Append-relative span intervention — ADOPTED by mathematics audit #44 after the displayed type corrections

Fix the append action family \(\mathcal A_+\) and its distance \(d_\infty^+\). An executable span intervention is a deterministic, prospectively declared total endomap

\[
s:Z\to Z.
\]

It replaces exactly one declared token span and leaves every other token unchanged. Span, type, and tokenization failures are sent to declared observable failure states in \(Z\), never removed. It is *admissible on append-future places* exactly when

\[
x\sim_+y\Longrightarrow sx\sim_+sy.
\]

Exactly then it descends to \(\bar s:Q^+\to Q^+\). A genuinely typed map between different carriers would instead require separately defined source and target quotients and is not used in Proposition 6.

Nonexpansiveness with respect to \(d_\infty^+\) is the stronger condition

\[
d_\infty^+(sx,sy)\leq d_\infty^+(x,y),
\]

and is not automatic. If \(s\) is instead added to D1's action alphabet and the future distance is redefined over arbitrary words containing \(s\), Theorem 1 makes \(s\) nonexpansive for that enlarged distance; but Theorem 4's append-only \(N-1\) conclusion no longer follows. An intervention is therefore not "a legal move that is not a continuation": in D1 every primitive legal move is a one-letter continuation. The append/intervention typing is the needed distinction.

### Proposition 6. Place change and registered-target-place realization by a span intervention — proved as an exact quotient characterization

Let \(s\) be a D8 intervention, let \(x\) be a registered source prompt, and let \(y\) be a prospectively selected, independently presented native prompt for the target denotation. Then:

1. \(s\) is place-changing at \(x\) exactly when

\[

[sx]_+\ne[x]_+
\iff
d_\infty^+(x,sx)>0.
\]
2. \(s\) is *registered-target-place-realizing* at \(x\), meaning that it realizes the registered target place relative to the declared response channels, exactly when
\[
[sx]_+=[y]_+
\iff
d_\infty^+(sx,y)=0.
\]
This is behavioral identity in the registered interface, not identity of hidden states or semantic state.
3. If \(s\) satisfies D8's congruence condition, these pointwise endpoint statements are values of a well-defined intervention map \(\bar s:Q^+\to Q^+\). Pointwise success alone does not prove descent on other representatives.

Proof. The first two equivalences are precisely D5's zero-kernel definition of the append-future quotient. The third is the standard quotient-map criterion. \(\square\)

Under Theorem 4, both endpoint distances are exactly determined by append words of token length at most \(N-1\) (or the channel-tightened bound). A horizon-\(2\) query table can witness place change and can falsify target identity, but cannot certify either full distance unless it also supplies a response-completeness certificate for every unmeasured branch.

## Asymmetry of finite access and surgeon worlds (ADOPTED by mathematics audit #44 after the displayed type corrections; round 39)

This extension separates two questions that the prompt-only formulation had conflated. First, what can finite response access establish about the exact future-response metric? Second, how can an analyst's hidden-state edit be compared honestly with moves and outputs available to a denizen? Theorem 7 is a standard finite-trace/coinductive asymmetry; no novelty is claimed. D9 and Theorem 8 add an analyst, called the surgeon, without promoting the surgeon's edit to a denizen move.

### Theorem 7. Asymmetry of finite response access — proved

For nonempty finite registered sets \(W_0\subset\mathcal W\) and \(C_0\subset C\), define the restricted distance
\[
d_{W_0,C_0}(x,y)
=
\max_{\substack{w\in W_0\\c\in C_0}}
D_c(r_c(T_wx),r_c(T_wy)).

\]

In every world satisfying D1--D4:

1. **Restricted access gives a lower bound:**

\[
d_{W_0,C_0}(x,y)\leq d_\infty(x,y).
\]

2. **Nonidentity is finitely witnessable.** If \(d_\infty(x,y)>0\), then there are a word \(w\) and channel \(c\) for which

\[
D_c(r_c(T_wx),r_c(T_wy))>0.
\]

Hence the singleton table \(W_0=\{w\}\), \(C_0=\{c\}\) already proves that \(x\not\sim y\).

3. **Finite agreement does not certify identity uniformly over D1--D4.** Even with a fixed two-action append alphabet and the same nonempty finite channel family in the restricted and full metrics, every finite word table admits a finite-memory append world and a pair with

\[
d_{W_0,C}(x,y)=0
\quad\text{but}\quad
d_\infty(x,y)=1.
\]

Proof. The first claim follows because the restricted index set is contained in \(\mathcal W\times C\). If the supremum defining \(d_\infty\) is positive, not every nonnegative term can be zero, which proves the second claim.

For the third claim, fix the append actions \(\mathcal A=\{a_0,a_1\}\), where \(a_i\) appends token \(i\), and let \(\sigma(w)\) be the execution-order binary string defined as in Theorem 4. Choose a nonempty word \(u\notin W_0\), which is possible because \(W_0\) is finite. Let the token vocabulary contain distinct markers \(X,Y\) in addition to \(0,1\), take \(Z=\{X,Y,0,1\}^*\), and set \(x=X\), \(y=Y\). Take \(C\) to be the prescribed nonempty finite channel family and put \(N=|u|+1\). For every \(c\in C\), use the two-point outcome space with total-variation distance and define

\[
r_c(z)
=
\begin{cases}
\delta_1,&\operatorname{suf}_N(z)=X\sigma(u),\\
\delta_0,&\text{otherwise}.
\end{cases}
\]

The response has memory at most \(N\). At \(u\), the two responses are \(\delta_1\) and \(\delta_0\). For every other word \(v\), they agree: when

\(|v|\leq |u|\), the only accepting suffix would require \(v=u\); when \(|v|\geq N\), the shared binary append has erased the initial marker from the final \(N\) tokens. Thus \(u\) is the only discriminating word, \(d_\infty(x,y)=1\), and the table \(W_0\) reports zero. The continuation tree has \(2^h\) words at depth \(h\). \(\square\)

#### Finite-state abstraction corollary — proved; sufficient, not necessary

Suppose there are a finite set \(S\), a map \(s:Z\to S\), response maps \(\widehat r_c:S\to\mathcal P(O_c)\), and deterministic updates \(\delta_a:S\to S\) such that

\[
r_c=\widehat r_c\circ s,
\qquad
s(T_{ax})=\delta_a(s(x))
\]

for every \(a,c,x\). Replacing \(S\) by \(s(Z)\) if necessary, this makes \(s\) a surjective morphism to a finite Moore machine. Induction on words gives \(s(T_{wx})=\delta_w(s(x))\), so every response discrepancy factors through the finite synchronous pair graph on \(S\). Consequently

\[
d_\infty=d_{|S|^2-1}.
\]

If \(\mathcal A\) and \(C\) are also finite, the table containing **all** channels and all words of length at most \(|S|^2-1\) is finite and certifies exact identity. With an infinite channel family, a finite response-complete channel basis is an additional premise.

This finite-state condition is not necessary. An invariant, bisimulation, or other proof controlling every unseen branch can certify identity in an infinite-state world. The negative result says that finite *agreement alone*, without such a completeness proof, has no uniform identity implication over D1--D4.

For Theorem 4's explicitly registered suffix wrapper with finite vocabulary \(V\), one may take

\[
S=\bigcup_{k=0}^{N}V^k,
\qquad
|S|=\sum_{k=0}^{N}|V|^k,
\]

or \(|V|^N\) under a padded fixed-length convention. Thus a finite abstraction does exist in that registered world, and Theorem 4 supplies the much tighter depth bound \(N-1\); the exact all-branch table is nevertheless astronomical. For a full-context model without a suffix wrapper, Theorem 4 does not register this abstraction. A finite context/overflow carrier can still invoke Theorem 1's finite corollary, but it is likewise computationally vacuous at LM scale.

Finite access therefore always supplies lower bounds on $d_\infty$, and a positive lower bound certifies nonidentity and place separation. A nontrivial upper bound requires a separate unseen-branch argument: exhaustive finite-state coverage, an invariant, contractive or analytic tail control, or a proof that a witnessed word attains the supremum. Attainment cannot be inferred from the witness itself. For an exact LM identity claim under an incomplete finite table, the honest status is **refuted** when a robust positive witness is found and **not refuted at the registered access** otherwise; it is not certified by a plateau. Approximate tolerance claims remain distinct and must use the governance amendment's effect-size and uncertainty rules.

Lay so-what: *an inhabitant can prove that two places differ with one decisive future, but agreement on every future it happened to inspect proves sameness only when a map or invariant also controls the futures it did not inspect.*

### D9. Denizen and surgeon worlds — ADOPTED by mathematics audit #44 after the displayed type corrections

A **denizen world** is a D1--D4 world

$$
\mathfrak D=(Z,\mathcal A_D,C,(r_c),(D_c)).
$$

A **surgeon extension** keeps the same carrier, response channels, response laws, outcome metrics, and every denizen transition map unchanged, and adds total deterministic surgeon transition maps. Thus $\mathcal A_D\subseteq\mathcal A_S$ and $T_a^S=T_a^D$ for every $a\in\mathcal A_D$. Every invalid-phase, missing-site, shape, or tokenization case enters a declared observable absorbing failure state on which every action and response law is defined.

$$
\mathcal A_D\subseteq\mathcal A_S.
$$

The extra moves may include prospectively declared residual edits at declared execution sites. The denizen and surgeon metrics are

$$
d_\infty^D(x,y)
=\sup_{w\in\mathcal A_D^*,c\in C}
D_c(r_c(T_wx),r_c(T_wy)),
$$

$$
d_\infty^S(x,y)
=\sup_{w\in\mathcal A_S^*,c\in C}
D_c(r_c(T_wx),r_c(T_wy)).
$$

A residual-edit instantiation must declare a prompt-phase subset $P\subseteq Z$, site-phase subsets $H_\ell\subseteq Z$, and observable

absorbing failure states \(F\subseteq Z\). Register a total site lift
\(\iota_\ell:P\to H_\ell\cup F\) and its valid domain
\(P_\ell=\iota_\ell^{-1}(H_\ell)\). Define every denizen and surgeon
transition as a total endomap of \(Z\), and define the unchanged emitted
response laws on every phase, including \(F\). Bridge endpoints must lie in
\(P_\ell\). Without these declarations, the comparison is ill-typed.

### Theorem 8. Surgeon refinement and denizen reachability — proved

Let \(\mathfrak S\) be a D9 surgeon extension of \(\mathfrak D\). Then:

1. For every \(x,y\in Z\),
\[
d_\infty^D(x,y)\leq d_\infty^S(x,y).
\]
Hence \(\sim_S\subseteq\sim_D\), and
\[
\pi:Q^S\to Q^D,
\qquad
[x]_S\mapsto[x]_D,
\]
is a well-defined surjective nonexpansive map. Surgeon places refine
denizen places.
2. Define the denizen-reachable places from \(x\) by
\[
\operatorname{Reach}_D(x)
=\{[T_wx]_D:w\in\mathcal A_D^*\}.
\]
A surgeon move \(m\in\mathcal A_S\setminus\mathcal A_D\) is
**denizen-place-realizable at \(x\)** exactly when
\[
[mx]_D\in\operatorname{Reach}_D(x),
\]
equivalently, when there exists \(w\in\mathcal A_D^*\) such that
\[
d_\infty^D(mx,T_wx)=0.
\]
The stronger condition
\[
\exists w\in\mathcal A_D^*:
d_\infty^S(mx,T_wx)=0
\]
is **surgeon-place denizen realization**. It implies denizen-place
realization, but the converse need not hold because surgeon observations
may split one denizen place.

Proof. The free-word inclusion
\(\mathcal A_D^*\subseteq\mathcal A_S^*\) makes the denizen supremum a

restriction of the surgeon supremum, proving the inequality. If
\(x\sim_Sy\), the inequality gives \(x\sim_Dy\), so \(\pi\) is well-defined;
every denizen class has the preimage \([x]_S\), and the same inequality proves
nonexpansiveness. The two realization equivalences are D5's zero-kernel
definition applied respectively to \(Q^D\) and \(Q^S\). \(\square\)

The surgeon move need not descend to a map on \(Q^D\): that requires the
additional congruence

\[
x\sim_Dy\Longrightarrow mx\sim_Dmy.
\]

Theorem 1 makes \(m\) nonexpansive for \(d_\infty^S\), not automatically for
\(d_\infty^D\).

### Native bridge test — ADOPTED by mathematics audit #44 after the displayed type corrections; exact equality is finitely refutable, not finitely confirmed in general

Fix before inspection \(x,y_s\in P_\ell\), where \(y_s\) is an exact
prospectively registered prompt selected as the native target for label \(s\),
and fix a total surgeon-only action
\(m_s\in\mathcal A_S\setminus\mathcal A_D\) that is phase-valid on
\(H_\ell\) and failure-total elsewhere. The exact native bridge discrepancy is

\[
B_s(x,y_s)
=
d_\infty^D
\bigl(m_s\iota_\ell(x),\iota_\ell(y_s)\bigr).
\]

The edit is **registered-target-place-realizing in denizen behavior** for this
pair exactly when \(B_s(x,y_s)=0\). This compares a surgeon-produced internal
configuration using only denizen moves and the unchanged emitted-output
interface. It does not make the edit a denizen move, identify hidden states,
or establish denizen reachability from the source. The latter additionally
requires \([\iota_\ell(y_s)]_D\in
\operatorname{Reach}_D(\iota_\ell(x))\).

By Theorem 7, any denizen word and channel with positive discrepancy refutes
the exact bridge claim. Failure to find such a word only fails to refute it at
the registered access unless an independent completeness invariant controls
all remaining branches. Floating-point and population experiments must use
predeclared approximate criteria; an exact zero table is diagnostic only.

### Record-reading proposition — supported qualitative interpretation; exact metric disjunction not licensed

Within the audited frozen-model record, no tested residual intervention
established both material content-specific change in the registered native
response behavior and registered-target-place realization or denizen
reachability. Some constructions failed to show material target-specific
change at their declared readouts and easiest controls; others produced

lexical, verbalizer, prompt-boundary, or construction-bound effects without establishing target-place identity or reachability.

This reading does **not** license either exact half of the proposed dichotomy

\[
d_\infty^D(mx,x)=0
\quad\text{or}\quad
[mx]_D\notin\operatorname{Reach}_D(x)
\]

for every tested move. The finite null results cannot prove the first claim, and the record did not exhaust denizen words or reachable places to prove the second. All audit never-say lists, especially the frozen-model and audit-#39 boundaries retained in `STATE.md`, remain binding.

### Round-39 artifact ruling after audit #44

Theorem 7 ends the search for a universally positive finite-query identity certificate: finite agreement needs an external completeness invariant. Before any native-bridge preregistration, one math-first specification must instantiate the common phase carrier and total transitions, define the finite registered bridge lower bound, define an approximate population criterion relative to replay and native target-fiber variation, and state the proximal positive control and every outcome implication. Only after that specification is audited may a small real-model refutation-oriented bridge artifact be considered. Exact bridge equality remains diagnostic; `native_horizon_v1` remains unselected; no computation is authorized.

### Native bridge specification (proposed, rounds 40-42; audits #45-#47 corrections applied; audit #47 LOCK-READY — wording corrections only)

**Status.** The carrier, actions, restricted distance, excess-discrepancy estimands, controls, and outcome meanings below are **defined**. Totality and unchanged denizen maps are **proved from the case definitions**, and the finite registered lower-bound property is **proved**. Faithful transformer continuation and response-level intertwining are **conditional** on the registered computation-DAG cut and canonical token/mask/position/cache construction; deterministic fixtures must test those premises. The cross-prompt native paste and both centroid predictions are **conjectured**. This is repair pass 2 of at most three consecutive repair rounds after audit #46. No manifest or lock row exists, and no scientific forward pass is authorized.

#### One-model, one-site population — defined

Fix frozen `Qwen/Qwen3-1.7B-Base` at revision `ea980cb0a6c2ae4b936e82123acc929f1cec04c1`. Use only the existing intact, tokenization-verified explicit-legend rows for the 24 registered entities. For entity \(e_i\), let the source label be \(q_i=e_i\bmod8\) and the target label be

\[

s_i=(e_i+1)\bmod8.
\]

Choose one source prompt \(x_i\) and

> *three distinct, prospectively row-ID-selected intact target prompts; no stochastic independence is assumed*

forming

\[
\mathcal Y_{i,s_i}
=\{y_{i,s_i}^{(1)},y_{i,s_i}^{(2)},y_{i,s_i}^{(3)}\}.
\]

They come from three distinct registered templates under the outcome-blind row rule bound in `theory/EXPERIMENTS.md`. The base set therefore has \(24+24\times3=96\) prompts. These 24 entities are the whole registered population for the claim below, not a probability sample from a declared superpopulation.

There is one residual site: zero-based block \(\ell=16\), at the final token of the final record-tag occurrence, with \(h_{\ell,p}(x)\in\mathbb R^d\) the post-block residual (`hidden_states[17]`) at that position. The pooled preflight selected block 16 using a two-token span. The block-16 single-position site is unvalidated until the conjectured proximal site-sufficiency control is run; the prior preflight did not validate it.

Let \(\mathcal A_D=\{a_P,a_Q\}\). For each source unit, \(a_P\) appends the registered first query token and \(a_Q\) appends its corresponding complete query. Both are deterministic total maps; missing metadata, token mismatch, or context overflow enters a tagged failure. The registered word table is

\[
W_0=\{\epsilon,a_P,a_Q,a_Pa_P,a_Pa_Q,a_Qa_P,a_Qa_Q\},
\]

with D1's rightmost-first execution convention. The source-indexed literal strings and token IDs are fixed before outputs; the seven syntactic words are the same for every entity.

#### Common phase-typed carrier and canonical continuation — defined

Let \(\mathsf P_0\) be the 96 base prompts. Define the prompt phase \(\mathsf P\) as the closure of \(\mathsf P_0\) under finite registered macro appends up to the declared context limit. No new natural-language prompt family is introduced. Let

\[
F=\{f_{\rm phase},f_{\rm site},f_{\rm shape},f_{\rm token},
f_{\rm overflow}\}
\]

be tagged observable absorbing failures.

For a canonically tokenized registered input, let $G$ be the frozen transformer's deterministic computation DAG under the registered batch-one mask, position, and cache policy, and let $v_{\ell,p}$ be the edited post-block residual node. Put $D_v=\{v_{\ell,p}\}\cup\operatorname{Desc}(v_{\ell,p})$. The **canonical cut** is the graph-theoretic incoming boundary

$$
\partial^-D_v
=\{u\in V(G)\setminus D_v:
\exists d\in\operatorname{Desc}(v_{\ell,p})\text{ with }(u,d)\in E(G)\},
$$

together with any exogenous token/mask/position/cache-construction inputs not represented as vertices of $G$. Every path from outside $D_v$ into a descendant crosses this boundary. Thus it contains every non-descendant input needed to recompute all descendants of the edited residual, and no descendant of that residual.

A continuation record $\kappa\in K_\ell$ is exactly the registered values and construction metadata on that canonical cut, the exact provenance-bound token IDs of the originating registered input, the fixed tokens after $p$, and the accumulated append suffix. In particular, $K_\ell$ is not defined as an arbitrary bag of tensors that happens to make replay work.
Define

$$
H_\ell=K_\ell\times\mathbb R^d,
\qquad
Z=\mathsf P\;\sqcup\;H_\ell\;\sqcup\;F.
$$

Conditional on the registered construction being faithful, the deterministic response constructor $\operatorname{Cont}_\ell(\kappa,h)$ executes the complete canonical no-cache forward for the provenance-bound input and stored suffix with $h$ substituted at $v_{\ell,p}$, and returns the full next-token law at the answer position. Invalid records return their declared failure law. This is a total response constructor on valid site states, not a transition or an endomap.

Define the total site lift

$$
\iota_\ell:\mathsf P\longrightarrow H_\ell\cup F
$$

by running an unedited prompt through block $\ell$, extracting its canonical cut record and site vector, and returning the appropriate failure for a missing site, wrong tokenization, shape error, or overflow. Its valid domain is $\mathsf P_\ell=\iota_\ell^{-1}(H_\ell)$. Every $x_i$ and every member of $\mathcal Y_{i,s_i}$ must lie in $\mathsf P_\ell$. The lift is total on

\(\mathsf P\), but it is not an endomap of \(Z\).

For \(a\in\mathcal A_D\), define \(T_a^D:Z\to Z\) by cases:

1. on \(\mathsf P\), append the registered macro and remain in \(\mathsf P\),
or enter the declared token/overflow failure;
2. on \((\kappa,h)\in H_\ell\), append the same macro tokens to the
provenance-bound suffix in \(\kappa\), retain \(h\), and remain in
\(H_\ell\), or enter the same declared failure; and
3. on \(f\in F\), return \(f\).

A denizen append on \(H_\ell\) therefore adds future tokens under the same continuation construction. It never makes or reapplies a residual edit.

The primitive channel \(c_{\rm full}\) emits the full next-token law. The derived channel \(c_9\) is its fixed Markov pushforward to digits \(0,\ldots,7\) plus `other`. On valid prompt states, the response is the ordinary frozen model; on valid site states it is \(\operatorname{Cont}_\ell\). On failures the full outcome space includes a tagged failure symbol and \(c_9\) maps it to `other`. Both channels use normalized square-root Jensen--Shannon distance. Because \(c_9\) is a fixed pushforward of \(c_{\rm full}\), it is an interpretation channel and adds no independent refutation power.

For each registered surgeon action \(m\), define \(m:Z\to Z\) by replacing the \(\mathbb R^d\) component only on a matching valid \(H_\ell\) state, sending every nonmatching prompt/site/token/shape case to its declared failure, and fixing every state in \(F\). Put these actions in \(\mathcal A_S\setminus\mathcal A_D\). The surgeon extension uses exactly the same denizen maps, carrier, and response laws.

#### Carrier obligations — proved cases and conditional transformer premises

**Proved from the case definitions: unchanged denizen maps.** For \(u\in\mathsf P\) and \(a\in\mathcal A_D\), both worlds apply the same token append or failure map. The same equality holds on \(H_\ell\) and \(F\). Hence \(T_a^S=T_a^D\) on all of \(Z\), as D9 and Theorem 8 require.

**Proved from the case definitions: totality.** The tagged union exhausts \(Z\). Each denizen action has one branch on each summand. Each surgeon action returns an edited site state, a declared failure, or the same absorbing failure. Thus every denizen and surgeon action is a total endomap of \(Z\), and the case-defined response laws are total.

**Conditional transformer premises.** For every valid continuation record, the registered continuation constructor appends the macro to its provenance-bound suffix and executes the complete canonical no-cache forward with \(h\) substituted at \(v_{\ell,p}\). The 32-call fixtures test the conditional response-level intertwining

\[
r_c(T_w^D\iota_\ell(u))
=

r_c(\iota_\ell(T_w^D u)),
\qquad c\in C_0,
\]

on their registered subset. No equality of \(H_\ell\) records is claimed. A stronger state-level identity requires a separately defined canonical cut-update map \(U_w\), with \(U_w(\kappa_u)=\kappa_{T_wu}\), and direct cut-record comparison. These claims are conditional on the registered DAG cut and the canonical token/mask/position/cache construction. Any fixture failure is carrier implementation invalidity, not a scientific model result.

#### Finite registered bridge lower bound — defined; lower-bound property proved

Let \(C_0=\{c_{\rm full},c_9\}\). For any registered source, designated exact native target, and total surgeon edit, define

\[
B_{W_0,C_0}(x,y_s;m_s)
=d^D_{W_0,C_0}\!\left(m_s\iota_\ell(x),\iota_\ell(y_s)\right)
=\max_{\substack{w\in W_0\\c\in C_0}}
D_c\!\left(
r_c(T_w^D m_s\iota_\ell(x)),
r_c(T_w^D\iota_\ell(y_s))
\right).
\]

Because \(W_0\times C_0\subseteq\mathcal A_D^*\times C\), Theorem 7 gives

\[
B_{W_0,C_0}(x,y_s;m_s)
\le d_\infty^D\!\left(m_s\iota_\ell(x),\iota_\ell(y_s)\right).
\]

A certified positive discrepancy invokes Theorem 7 and refutes the exact bridge. A replay-robust measured exceedance without a certified numerical-error bound is recorded as a **tolerance-robust registered-access refutation in the registered numerical implementation**. Otherwise the exact bridge is only **not refuted at registered access**; finite agreement never confirms it.

#### Replay envelopes and excess-discrepancy estimands — defined

For entity \(i\), define

\[
R_i(m)=\operatorname*{median}_{y\in\mathcal Y_{i,s_i}}
d^D_{W_0,C_0}\!\left(m\iota_\ell(x_i),\iota_\ell(y)\right),
\]

\[
V_i=\operatorname*{median}_{\{y,y'\}\subset\mathcal Y_{i,s_i}}
d^D_{W_0,C_0}\!\left(\iota_\ell(y),\iota_\ell(y')\right),
\qquad
E_i(m)=R_i(m)-V_i.

\]

Here \(V_i\) is a three-pair within-fiber comparator. It is not a normalizer and does not certify that the target label fiber is behaviorally distinct. Neither the label nor its fiber is inferred from these distances.

For a registered action family \((m_i)_{i=1}^{24}\), the primary estimand is the exact registered finite-population mean

\[
\Theta_{24}((m_i))=\frac1{24}\sum_{i=1}^{24}E_i(m_i).
\]

Resampling the 24 entity clusters produces **entity-cluster stability bounds** for sensitivity to entity composition. The bounds make no sampling-coverage claim and are not confidence intervals for \(\Theta_{24}\). No superpopulation model is declared because the licensed claim concerns this complete, fixed 24-entity registry.

Let \(\mathcal Q\) be all eight registered endpoint families. Across both replay schedules define the endpoint-law replay discrepancy

\[
\eta=
\max_{\substack{i\in\{1,\ldots,24\},\,q\in\mathcal Q,\\
w\in W_0,\,c\in C_0}}
D_c\!\left(r_{i,c}^{(A)}(q,w),r_{i,c}^{(B)}(q,w)\right).
\]

The registered envelopes are

\[
\varepsilon_B=\max(\varepsilon_0,k_B\eta),\qquad k_B\ge2,
\]

\[
\varepsilon_E=\max(\varepsilon_0,k_E\eta),\qquad k_E\ge4,
\qquad
\tau=\varepsilon_E+\delta.
\]

Use \(\varepsilon_B\) for every individual bridge discrepancy and \(\varepsilon_E\) for every \(E\)-based status. The factors follow from the metric triangle inequality: moving both laws between replay schedules changes one endpoint-pair distance by at most \(2\eta\). Maxima and medians are 1-Lipschitz under a uniform perturbation, so \(R_i\) and \(V_i\) each change by at most \(2\eta\); their difference \(E_i=R_i-V_i\) changes by at most \(4\eta\). In each paired contrast the common \(V_i\) cancels, leaving a difference of two \(R_i\) terms, so \(4\eta\) also bounds replay drift in \(\Delta_{\rm src}\) and \(\Delta_{\rm spec}\). The preregistration binds \(\varepsilon_0,k_B,k_E,\delta\), the replay-invalidity ceiling, and the stability-resampling algorithm before any scientific output.

If \(U_E(m)\) and \(L_E(m)\) are the registered upper and lower entity-

cluster stability bounds for \(\Theta_{24}(m)\), then
\(U_E(m)\le\tau\) is target-fiber fit, \(L_E(m)>\tau\) refutes that approximate
fit criterion, and overlap is inconclusive. An \(E_i\le0\) value says only
that the endpoint's median restricted discrepancy from the three native
targets is no larger than their registered median pairwise discrepancy. It
does not prove equality, target-place identity, unseen-future control,
behavioral fiber separation, an edit effect, or validity for every entity.

#### Proximal control, source control, and specificity control — defined

For each \(i\), take \(y_i^*=y_{i,s_i}^{(1)}\). The **same-carrier paste-back
fixture** replaces \(h_{\ell,p}(y_i^*)\) by the identical vector while keeping
\(y_i^*\)'s continuation record. Its endpoint is equal in exact arithmetic;
a discrepancy beyond the replay floor makes the artifact
**INVALID — SITE CARRIER/HOOK**.

The **conjectured proximal site-sufficiency control** is the total surgeon
action

\[
m_i^{\rm nat}(\kappa_i^x,h)
=(\kappa_i^x,h_{\ell,p}(y_i^*)),
\]

with declared failures elsewhere. Generally
\(\kappa_i^x\ne\kappa_i^{y_i^*}\), so native paste is not equal to the native
target by construction. Its PASS is necessary before scientific
interpretation of the centroid arm, but does not validate centroid formation,
averaging, target specificity, or the centroid edit.

The **unedited-source family** \(m_i^0\) keeps the source continuation record
and its original residual unchanged. It is evaluated through the same hook
path as the edited families, so an apparent target-fiber fit must improve on
the actual source endpoint rather than inherit source behavior.

For every registered target label \(s\), define explicitly

\[
\mathcal Y_{s,-e_i}
=\bigcup_{\substack{j\ne i\\s_j=s}}\mathcal Y_{j,s}.
\]

The correct entity-excluding centroid is

\[
\mu_{s_i,-e_i}
=\frac{1}{|\mathcal Y_{s_i,-e_i}|}
\sum_{y\in\mathcal Y_{s_i,-e_i}}h_{\ell,p}(y),
\]

and \(m_i^{\rm cent}\) replaces the source vector by
\(\mu_{s_i,-e_i}\). This is a new within-Qwen surgeon edit motivated by prior
registered populations; it does not inherit an audit-#38/#39 intervention.
Vector averaging is analyst-authored structure, not a denizen primitive or

native geometry.

Set the prospectively cycled wrong label to

\[
t_i=(s_i+1)\bmod8.
\]

Form \(\mu_{t_i,-e_i}\) from \(\mathcal Y_{t_i,-e_i}\) by the same rule and let \(m_i^{\rm wrong}\) paste that vector into the source continuation. The paired mean contrasts are

\[
\Delta_{\rm src}(m)
=\frac1{24}\sum_i[E_i(m_i)-E_i(m_i^0)],
\]

\[
\Delta_{\rm spec}
=\frac1{24}\sum_i[E_i(m_i^{\rm cent})-E_i(m_i^{\rm wrong})].
\]

Negative values favor the named edit. The material thresholds \(\delta_{\rm move}>0\) and \(\delta_{\rm spec}>0\) are bound before outputs. All stability bounds for these paired contrasts resample whole entities and preserve every within-entity target, word, channel, family, and replay.

#### Registered statuses and exact implications — defined

Write \(L_{\rm src}(m),U_{\rm src}(m)\) for the entity-cluster stability bounds on \(\Delta_{\rm src}(m)\), and \(L_{\rm spec},U_{\rm spec}\) for those on \(\Delta_{\rm spec}\).

1. Any manifest, row, tokenization, site, shape, response-totality, replay, DAG-cut continuation, response-level intertwining, token-order, or same-carrier paste-back failure makes the run **INVALID**. No scientific edit verdict survives.
2. Native paste **PASSES** only if both target-fiber fit \(U_E(m^{\rm nat})\le\tau\) and prospective improvement over source \(U_{\rm src}(m^{\rm nat}) \le-(\varepsilon_E+\delta_{\rm move})\) hold. It **FAILS** if \(L_E(m^{\rm nat})>\tau\) or \(L_{\rm src}(m^{\rm nat}) >-(\varepsilon_E+\delta_{\rm move})\); every other valid case is **INCONCLUSIVE**. Even a PASS does not validate centroid formation.
3. Unless native paste PASSES, the centroid endpoints are reported **DIAGNOSTIC ONLY — PROXIMAL CONTROL NOT PASSED**.
4. Conditional on native-paste PASS, the correct centroid **PASSES** only if it fits the target fiber \(U_E(m^{\rm cent})\le\tau\), improves over source \(U_{\rm src}(m^{\rm cent}) \le-(\varepsilon_E+\delta_{\rm move})\), and improves over the wrong-label

centroid \(U_{\rm spec}\le-(\varepsilon_E+\delta_{\rm spec})\).
5. Conditional on native-paste PASS, the centroid criterion is **REFUTED** if
\(L_E(m^{\rm cent})>\tau\),
\(L_{\rm src}(m^{\rm cent})
>-(\varepsilon_E+\delta_{\rm move})\), or
\(L_{\rm spec}>-(\varepsilon_E+\delta_{\rm spec})\). Every other valid case is
**INCONCLUSIVE**. This refutes this population criterion at this site and
access, not all residual bridges.
6. Independently, a certified positive individual discrepancy invokes
Theorem 7. Without a certified numerical-error bound, an individual
discrepancy exceeding \(\varepsilon_B\) in both replays receives only the
tolerance-robust registered-access numerical-implementation wording above.

#### Surgeon-only claim wall — defined

This is a surgeon-world artifact. The lift, residual capture, paste, centroid formation, and centroid write are not denizen moves; only \(W_0\)'s append actions are denizen futures. A full centroid PASS licenses only:

> *Across the 24 registered entities, the correct centroid edit has registered-access mean excess discrepancy within the native target-fiber criterion and prospectively improves that criterion relative to both no edit and the cycled wrong-label centroid.*

It never licenses “Qwen has a register,” “a causal bridge exists,” exact target-place identity, denizen reachability, unseen-future control, hidden-state identity, fiber separation, storage, persistence, dimension, native latent mathematics, every-entity success, or model-family generality.

#### Scope, exact call unit, compute contract, and ratio

The scope is one frozen model, one block, one token position, 24 entity clusters, three native target presentations per entity, seven denizen words, and two response channels derived from one full law. Per entity the eight endpoint families are the three clean native targets, same-carrier paste-back, native paste, unedited source, correct centroid, and wrong-label centroid. With two replay schedules, the pre-deduplication count is

\[
24\times8\times7\times2=2{,}688.
\]

One call unit is one batch-one, cache-disabled invocation of the frozen model that emits one full-vocabulary next-token law for one unique `(replay, entity, endpoint-family, word)` tuple; cut/hook execution is part of that invocation. Deriving \(c_9\), computing distances, reusing already captured donor residuals, and forming pairwise comparisons add no call unit. The family tag distinguishes plain target execution from same-carrier hook execution, and replay is deliberately not deduplicated. The registered tuple table has no aliases, so the exact deduplicated scientific count is also \(2{,}688\).

Before any scientific call, a prospective **mechanical-only smoke subset** must test: (1) same-carrier paste-back identity to the replay floor; (2) registered DAG-cut continuation versus plain forward equality on unedited states; and (3) the D1 execution/token order for the word \(a_Qa_P\) (`Q P`). The preregistration fixes the subset and a smoke-derived CPU forecast: measured smoke seconds per call times \(2{,}688\) times a bound safety factor sets the hard wall. Forecast above 90 CPU minutes aborts the CPU artifact. Only then may one small GPU burst be offered, and only with explicit user approval and a smoke-demonstrated GPU-safe hook path. A lock row must bind the manifest hash, exact count, forecast, hard wall, runner/config hashes, constants, statuses, and abort rule before any scientific forward pass.

Round 41 adds no experimental apparatus and no artifact-bearing code \(0/0\); it is one theory/build round. After audit #45's \(30:13\) heartbeat, the measurement/governance-to-build ratio is \(30:14=2.14:1\), still above the \(2:1\) warning and below the \(5:1\) halt.

#### Audit #47 lock-readiness disposition

Audit #47 verified the seven repair families, the 72+1,272 dependency schedule, the 2,688 scientific identities, the 1,680 replay-scoped token/mode combinations, the 32-call mechanical smoke, the normalized metric and replay envelopes, and the absence of hidden calls, serialized cut records, and cross-replay donors. Verdict: LOCK-READY subject to the report's wording-only identity and provenance corrections. This authorizes runner/config construction, the mechanical smoke, forecast derivation, and---if valid---a pre-science lock row; no scientific forward pass is authorized before that row.

## Prior relational foundation (Rounds 1--12; superseded, retained for provenance)

The L1--L5 neighborhood foundation, context-rank definitions, and T1--T3 below are historical. Round 31 found L1 to be normalization, L2/L3 to be vacuous under unrestricted probe completion, L4 to require future closure, and L5 to be a tested presentation law rather than an adopted axiom. They remain here to preserve the record and audit boundaries; they are not co-active axioms beside D1--D7.

## Primitives

- \(X\): latent states, after observational quotient.
- \(C\): admissible probes/contexts.
- \(N_c(x)\subseteq X\): states accepted as substitutes for \(x\) under \(c\).
- \(c\otimes d\): conjunction of probes when admitted.
- \(G\): declared exact presentation changes, acting on states and probes.

A raw vector array is a presentation, not a latent space. No origin, addition, scalar multiplication, inner product, metric, or dimension is primitive.

## Axioms and status

### L1. Self-substitution — adopted

$$
x\in N_c(x)\qquad(x\in X,c\in C).
$$

### L2. Finite conjunction — adopted for the completed probe family

The completed family $C^*\supseteq C$ is closed under finite conjunction: for every $c,d\in C^*$, $c\otimes d\in C^*$ and

$$
N_{c\otimes d}(x)=N_c(x)\cap N_d(x).
$$

A finite measured probe table need not already contain its conjunctions and therefore does not inherit the topological conclusion by itself.

### L3. Local refinement — conditional

A **topological latent system** has a conjunction-closed completed probe family $C^*$ satisfying, for $x,y\in X$ and $c\in C^*$,

$$
y\in N_c(x)\Longrightarrow
\exists d\in C^*;N_d(y)\subseteq N_c(x).
$$

This is not assumed of the first finite measurement. Its empirical analogue is refinement-defect rate.

### L4. Observational separation — adopted by quotient

$$
\bigl[\forall c:\ y\in N_c(x)\ \text{and}\ x\in N_c(y)\bigr]
\Longrightarrow x=y.
$$

### L5. Presentation covariance — adopted for declared exact maps

For $g\in G$,

$$
g[N_c(x)]=N_{gc}(gx),
\qquad g(c\otimes d)=gc\otimes gd.
$$

Which architecture changes belong to $G$ is a separate identification problem. Independently trained models are not presumed isomorphic.

### Contextual non-collapse — retired as an axiom

Existence of one reversal is noise-sensitive. It is replaced by probe-table context rank as a descriptive diagnostic, not an intrinsic invariant of $X$.

## Definitions

### Closeness profile

\[
\Phi_x(y)=\{c:y\in N_c(x)\},
\qquad
y\succeq_x z\iff\Phi_x(z)\subseteq\Phi_x(y).
\]

This relation may be directed, partial, and context-sensitive.

### Finite context rank

A quasi-metric is \(d:X^2\to[0,\infty)\) with \(d(x,x)=0\), positive off-diagonal entries, and the triangle inequality; symmetry is not required. For finite \(X,C\),

\[
\kappa(X,C,N)=\min k
\]

such that quasi-metrics \(d_1,\ldots,d_k\), a map \(i:C\to[k]\), and anchor-dependent radii \(\rho_c:X\to(0,\infty]\) satisfy

\[
N_c(x)=\{y:d_{i(c)}(x,y)<\rho_c(x)\}.
\]

Context rank measures incompatible ordinal cuts in the declared relational table \((X,C,N)\), not calibrated magnitude or geodesic structure. It is invariant under isomorphism of that full table. It is not an invariant of the state carrier \(X\), a stored representation, or a latent space independent of its probe family: adding, removing, regrouping, thresholding, or adversarially choosing probes can change it.

For a graded probe \(r_c(x,y)\), enlarge the neighborhood family by every strict sublevel cut and require all cuts from the same \(c\) to share \(i(c)\). The result is **graded context rank**; it introduces no arbitrary single tolerance.

### Cross-realization transportability

For independently trained systems, align states by an external identifier and measure agreement of directed signs, context-incompatibility edges, and neighbor rankings. This grades probe transportability; it is not an identity axiom.

## Theorems and status

### T1. Induced topology — standard basis lemma, conditional

Assume L1 and L4, and assume L2 and L3 on the conjunction-closed completed family \(C^*\). Then the sets \(N_c(x)\), for \(c\in C^*\), form a basis for a \(T_0\) topology. Declared presentation maps are homeomorphisms under L5.

Proof: local refinement supplies a basic neighborhood at each point of a basic intersection; the explicitly assumed conjunction closure refines the two supplied neighborhoods; separation gives \(T_0\). This is the standard neighborhood-basis theorem with operationally named basic sets, not yet a substantive constraint on a measured latent system. Full proof:

`dialogue/001.md`.

### T2. Finite chain representation — exact but geometrically vacuous

Assume L1 and finite \(X,C\). Then \(\kappa=1\) iff, for every \(x\),

\[
\forall c,d:\quad
N_c(x)\subseteq N_d(x)\ \text{or}\ N_d(x)\subseteq N_c(x).
\]

Necessity follows because balls with one center are radius-ordered. For sufficiency, order states by their neighborhood-membership profiles at each anchor, assign distinct profile classes values in \([1,2)\), set the diagonal to zero, and cut at suitable radii. All nontrivial two-edge paths have length at least 2, so the triangle inequality holds. Full proof: `dialogue/001.md`.

Audit boundary: the \([1,2)\) construction makes the triangle inequality automatic and imposes no coherence across anchors or paths. T2 therefore says only that one arbitrary anchorwise row-order represents a nested family of cuts. Calling that representation a quasi-metric contributes no finite geometric content. T2 is retained as a chain-representation lemma and as a warning that a non-degenerate native geometry needs stronger axioms.

### T3. Probe-table coloring identity — exact, definition-driven

Join contexts \(c,d\) when their neighborhoods are incomparable at some anchor. Then

\[
\kappa(X,C,N)=\chi(G_C).
\]

Each color class satisfies T2; contexts represented by one quasi-metric cannot share an incompatibility edge.

For graded probes, join two probes when any pair of their sublevel cuts is incomparable, and require all cuts from one probe to share a color. The same proof gives graded context rank as the chromatic number of this probe graph.

Audit boundary: T3 converts the definition of incompatibility into graph coloring; the definitions do the substantive work. The identity computes the chosen probe table efficiently but does not discover a dimension or invariant of the latent state space independent of \(C\).

## Empirical interpretation boundary

An observation that between-block reversal rate exceeds within-block paraphrase reversal rate can recover the hand-authored block taxonomy rather than native latent structure. In particular, \(B>W\) is insufficient when different cells condition on different robust-pair subsets or omit different undefined cells. Any future use of \(Q=B/W\) must include a common-support or explicit missingness analysis, probe-family resampling, and an independently defined behavioral endpoint. Without those controls, \(Q\) and empirical

\(\widehat\kappa\) describe only the instrument.

Neither T1--T3 nor any possible NLM-001 outcome could earn the sentence "cosine similarity is the wrong object for latent spaces." NLM-001 could at most have shown that, for its lexical items and carrier probes, decoder-induced KL orderings vary by context and outperform the tested baselines. The stronger claim additionally requires a competitive decoder-aware geometry, decoder-independent outcomes, presentation changes, and replication beyond lexical input embeddings.

## Open problems

1. Find a non-degenerate invariant that constrains magnitude, paths, or cross-anchor coherence; T2 makes the triangle inequality vacuous on finite data.
2. Characterize the global-radius version \(\rho_c(x)=\rho_c\), where context scales are comparable across anchors.
3. Give infinite-system quasi-metrization conditions without assuming first countability by fiat.
4. Decide when a probe measures semantics rather than decoder behavior; cross-realization agreement is evidence, not a solution.
5. Measure whether L3 holds approximately before treating the empirical probe system as topological.
6. Compete closeness against information-geometric and denotational primitives; do not add evidence-update or typed composition merely by extending the failed lexical-KL instrument.

## Round 12 — residue of the frozen-encoder world

The frozen-encoder line is now closed as a scope decision, with the NLM-006b identity gate kept intact. All four displaced image families passed the calibrated displacement test and had complete support, but their fine-label preservation rates were 0.458, 0.317, 0.185, and 0.416, below the locked `p_e >= 0.80` threshold. The chart comparison therefore remains descriptive OOD evidence, not a native transport verdict. The small `ST>TS` effect of roughly 0.035 on these outside-class edits is a measured order sensitivity, not yet a law.

Under the guiding question—what would a denizen of this world need in order to navigate it?—the denizen of a trained encoder's world inherits three pieces of equipment:

1. a **task-effective chart metric**: chart nearness is the best measured one-step consequence predictor among the tested constructs;
2. **affine-path smoothness under the trained representation**: chart-straight routes are coherent for the measured trained-world readouts, while the random-init chart loses that regularity; and
3. a chart that **degrades gracefully under identity-destroying moves**: absolute consequence prediction worsens under crop, inversion, mixing, and

occlusion, but the chart remains ahead of the tested native candidates in the descriptive transported-pair comparison.

What we never found is equally important: no native construct we built—probe profiles, Fisher pullback, or their transport-aware forms—competes with the chart on a held-out endpoint. This is not a proof that native mathematics is impossible, nor evidence that cosine is intrinsic. It says that this frozen encoder hands its denizen a useful map; it does not show the denizen discovering a deeper law of the latent world.

The next navigation primitive should therefore be lawful transport itself: LM residual streams, where the forward pass is the world's move and a map must predict the successor of a state. This makes dynamics an object of measurement rather than treating an analyst-chosen image edit as the move.

## Round 15 — first measured instance of Navigation requirement (e), laws

NLM-007 is the first measurement in this program that instantiates requirement (e) as a law rather than only as a probe relation or a chart comparison. Its world supplies the move: one causal-LM block transports a slot state from `z_l,c(w)` to `z_(l+1),c(w)`. Its candidate law is a field fitted on calibration words and carrier blocks and tested on held-out carrier blocks; its consequence is judged in the world's own currency, the downstream next-token law at the same slot position.

The fallback gives bounded evidence for one such law. At `L8->L9`, the ridge field clears the amended chart and word-mean gates on successor cosine and both completed-law readouts, with positive clustered lower bounds, full support, and a carrier-shuffled null below the field. Thus a denizen can learn transport on some contexts and reuse it on others. The law is affine but not low-rank at rank `<=128`, and the cross-carrier field exceeds the within-carrier oracle; the latter makes a carrier-specific explanation less adequate, not impossible.

The boundary is equally part of the result. `L0->L1` is lexical persistence, not a reusable state-dependent law. `L27->L28` is not adjudicable because the old completed endpoint read at a disconnected last-token location; the corrected endpoint reads the next-token law at the substituted slot itself. The two-pair gate is therefore not yet met, and the result remains a single-model, shared-word interpretability result. The remaining three pairs are predeclared for the next measurement, with `L12->L13` predicted to provide the second qualifying pair.

What would make this law native rather than an artifact of one model's chart is not a more elaborate fit on the same cells. It must survive a class-stratified unseen-word split with disjoint calibration/test words inside the same carrier-block design, and it must recur under the same amended protocol in a second model family (SmolLM2 or Gemma), with revisions, nulls, completed-law readouts, and support gates pinned. Until both follow-ups pass, requirement (e) has a first measured instance, not a model-independent law of latent space.

## Round 17 — corrected evidence for Navigation requirement (e)

The corrected six-pair slot-position rerun changes requirement (e)'s status from a single-pair, successor-plus-void-endpoint observation to bounded corrected evidence for the registered dynamics-map criterion. `L8->L9`, `L12->L13`, and `L27->L28` each clear the three `>=0.05` chart-lead gates, the three `>=0.02` word-mean separation gates, the carrier-shuffle gate, and the support gate, with positive clustered lower bounds where required. The reduced `20/500` budget makes this exploratory corrected evidence rather than a full-budget confirmatory result.

The permitted claim is narrow: **a full-dimensional, regularized affine predictor wins within this finite ladder** on these shared-word, held-out-carrier pairs, including the corrected downstream law at the substituted slot. This is a coordinate-dependent predictor result. It is not yet a native law, intrinsic geometry, or language-model-general invariant. The `L27->L28` successor is on normed vectors and is reported with that qualification. The required class-stratified unseen-word split and second model-family replication remain before requirement (e) can support a claim beyond this one-model interpretability result.

## Round 18 — requirement (e) after the identity null

The predeclared identity-plus-residual moot-maker changes the status of the NLM-007 law claim. The six-pair run exceeded its hard budget (`4540.8 s` versus `3300 s`), so it earns no new gate claim; however, the conservative withdrawal test remains valid. At `L8->L9` and `L12->L13`, `Yhat = X + mean_cal(Y-X)` closes the ridge lead on successor cosine, corrected slot skill, and corrected slot ordering. The prior finite-ladder wording and its native-law interpretation are withdrawn for exactly those pairs, so the Round 17 numerical two-pair criterion does not survive as a claim.

`L4->L5` and `L20->L21` retain small `0.02–0.03` point-estimate remainders but remain non-qualifying and live; they do not replace the withdrawn pairs. `L27->L28` stays in its post-norm/direct-head family, and its identity result is not a meaningful baseline because it compares a raw state with a normed target. Requirement (e) therefore remains unearned as a native law: NLM-007 now gives a bounded decomposition of a finite coordinate experiment into persistence plus a shared displacement, not a state-dependent affine invariant.

*(Audit #7, 2026-08-28: the closure rule is a conservative post-hoc one-sided policy; the required wording is "consistent with identity plus a calibration-mean displacement under this shared-word, held-out-carrier design; whether the displacement is carrier-, state-, or word-dependent is unresolved". Authoritative text: `theory/EXPERIMENTS.md`, Tier-3 audit #7.)*

Under the native-world reading, the lawful object to measure next is the displacement `Δ=Y-X`. A denizen's “same place” is observational equivalence under declared probes and downstream consequences, not equality of stored coordinates; a move may preserve that place's identity while adding a shared

displacement that changes the response law. The displacement ladder must first test whether any state-dependent component remains after the constant and word-conditioned displacement means are removed; only then should a forward-time append-token move be interpreted as a law rather than another coordinate regression.

## Round 19 — motion and consequence as navigation requirements

*(Wording narrowed by Tier-3 audit #8: “displacement variation beyond the word-conditioned mean; carrier/template vs state dependence unresolved”; `L20->L21` = one bounded qualifying pair. Authoritative text: `theory/EXPERIMENTS.md`, Tier-3 audit #8.)*

The displacement ladder gives one bounded qualifying pair at `L20->L21` and strong displacement-coordinate separation at `L8/L12`, but the same-slot law barely registers the middle-depth direction. This does not warrant a new primitive called consequential motion. Instead, navigation requires a typed consequence predicate over a move and a response law: whether the endpoint is observationally distinguishable from the start under the declared probes and downstream law. “Same place” is consequently an observational quotient, while “consequential motion” is a relation on transitions in that quotient. It may become a useful native definition if stable across endpoints and presentations, but it is not yet an axiom or an established invariant.

The next test is forward-time transport. For an appended sentinel, measure the state at the final original position before append against the sentinel's state at the next position, and read the completed law at that sentinel position. Identity, shared-mean displacement, and word-conditioned displacement are the required null ladder before a richer law. A sentinel token-identity control and an original-terminal-position locality control decide whether a result reflects a causal next-position move or merely a token/readout artifact.

## Round 20 — forward-time empirical boundary

*(Tier-3 audit #9: "does not meet" is a nonpass under the historical contract, not a kill of forward transport; the within-style-family null planned below is an alignment-destruction diagnostic, not a clean style null. Authoritative text: `theory/EXPERIMENTS.md`, Tier-3 audit #9.)*

The forward-time experiment is the first measurement whose move is the world's own append-token transition and whose consequence is read at the resulting next position. In the present one-model, shared-word, held-out-carrier design, the sentinel displacement is predictable from the preceding state beyond the word-conditioned mean from `F4` onward, and the sentinel-position law registers that variation in cosine and skill. This is a candidate instance of a native law of motion, not an earned native law.

The primary period arm does not meet its preregistered two-of-five same-sentinel criterion: only `F20` qualifies. The comma control/replication has two qualifying layers, `F12` and `F20`, but cannot rescue the primary arm.

The evidence therefore adds no new axiom. It sharpens the empirical boundary: state-predictive forward motion is compatible with a native law, while carrier/template-conditioned nuisance encoded in the state remains an equally live explanation. A native-law claim requires survival under presentation/style controls, a disjoint unseen-word split, and a second model family, with the same null ladder and downstream response-law test.

The across-word within-carrier ordering endpoint is retained for historical audit but is diagnosed as saturated for this question because word identity dominates it. Future consequence testing should use a predeclared rank of candidate completions by held-out KL to truth; this is a measurement redesign, not a change to any earlier gate or axiom.

---

## Closing deposit — Robust Port-Compression Conjecture (UNAUDITED)

*Added 2026-08-31 as the program's closing theoretical deposit. This is an open problem from Codex direction round 7 (R3), not an adopted theorem. Requires a dedicated mathematics audit before any claim.*

### Setup

Let $M$ be a decoder-only softmax-attention transformer with $L$ layers and model dimension $d$. After processing prefix $u$ of length $t$, its complete incremental state is

$$
C_t(u) = \bigl(t,\{K_{\ell,t}(u), V_{\ell,t}(u)\}_{\ell=1}^{L}\bigr).
$$

For token $a$, the append action $A_{t,a}: C_t \to C_{t+1}$ is the actual transformer computation, and $\rho_t: C_t \to \Delta(\mathcal{V})$ the next-token distribution.

An internal port $p_{\ell,t}: C_t \to \mathbb{R}^d$ (e.g., the newest-token residual after layer $\ell$) is an *internally sufficient carrier* if maps $F_{t,a}$ and $g_t$ exist such that

$$
p_{\ell,t+1} \circ A_{t,a} = F_{t,a} \circ p_{\ell,t},
\qquad
\rho_t = g_t \circ p_{\ell,t}.
$$

Equivalently, equality at the port is an output-respecting right congruence.

### Conjecture (Robust Port-Compression)

Let $M$ have generic, nondegenerate weights. Let $X_t$ contain an open set of continuous soft prefixes, and let $p_{\ell,t}: X_t \to \mathbb{R}^d$ be the residual at the newest token after a fixed layer $\ell$.

Once the behaviorally effective dimension of $X_t$ exceeds $d$, there exist soft prefixes $x, x' \in X_t$ such that

$p_{\ell,t}(x) = p_{\ell,t}(x')$ but for some admissible appended soft token $a$,

$$
\rho_{t+1}(xa) \neq \rho_{t+1}(x'a).
$$

Therefore no fixed layer's newest-token residual realizes the transformer's append-action process on all such prefixes. By contrast, the full distributed KV-cache carrier $C_t$ realizes it exactly.

### Why this might be true

1. A continuous map from a high-dimensional open domain into $\mathbb{R}^d$ must have nontrivial fibers.
2. Those histories can produce different keys/values at earlier layers.
3. Under nondegeneracy, a suitable future query distinguishes such cache configurations via $\mathrm{softmax}(qK^\top)V$.
4. If downstream computation is nondegenerate, that difference reaches $\rho$.

### Known gaps

- Raw prefix dimension need not equal behaviorally effective dimension.
- Two different caches might be future-equivalent (gauge symmetry).
- A separating soft query may exist even when no vocabulary token supplies it.
- Discrete natural-language prefixes admit exact injective encodings into $\mathbb{R}^d$.
- Approximate/finite-precision claims require a metric and robustness assumptions.
- Close prior art: Haris and Onak (COLT 2025) prove linear memory lower bounds for exact attention-based generation under communication complexity.

### Properties

This conjecture is:

- **Interior:** about the implementation, not just input-output behavior.
- **Coordinate-invariant:** whether the commuting laws exist is unchanged under arbitrary bijective recodings $\phi: P \to P'$.
- **Not yet novel:** internally sufficient carriers are standard in causal abstraction and state-realization theory.

### Connection to the adopted foundation

In the D1--D9 framework, this conjecture instantiates the surgeon-vs-denizen asymmetry (Theorem 8) at the implementation level. The KV cache is the full surgeon carrier $C_t$; a fixed-layer residual is a restricted port. The conjecture says this port is not an internally sufficient carrier once prefix complexity exceeds the port's dimension — the surgeon's full state space genuinely refines the port's quotient. This is the architectural reason a denizen limited to one residual tap cannot replicate the full model's append-action process, and connects the abstract place-refinement inequality $d_\infty^D \leq d_\infty^S$ to the concrete geometry of transformer

attention.

### Architectural comparison: transformers vs recurrent state-space models (UNAUDITED NOTE)

The conjecture's mechanism depends on a dimension mismatch between the full state carrier and the port. This mismatch is architecture-dependent:

**Transformer (softmax attention).** The full incremental state $C_t \in \mathbb{R}^{2Ldt}$ grows linearly with sequence length $t$. The port $p_{\ell,t} \in \mathbb{R}^d$ is fixed-dimensional. For $t \gg 1$, the dimension ratio $2Ldt/d = 2Lt \to \infty$. The fiber argument (a continuous map from a high-dimensional domain to $\mathbb{R}^d$ must have nontrivial fibers) applies once $\dim(X_t) > d$.

**Linear recurrent model (S4/Mamba/RWKV).** The full incremental state is a fixed-dimensional recurrent hidden state $h_t \in \mathbb{R}^n$ (or $\mathbb{C}^{n/2}$ for complex-diagonal SSMs), with $n$ independent of $t$. The update rule has the form

$$
h_{t+1} = A_t h_t + B_t x_t,
\qquad
y_t = C_t h_t + D_t x_t,
$$

where $A_t, B_t, C_t, D_t$ may be input-dependent (as in Mamba's selective mechanism) but the state dimension $n$ is fixed. A "port" reading $h_t$ at a fixed layer has the same dimension as the full state at that layer. The fiber argument therefore does not apply within a single layer: the port-to-state map can be the identity.

**Consequence for the program's central question.** The D1--D9 framework applies to both architectures. But the denizen-surgeon gap (Theorem 8) manifests differently:

- In a transformer, a fixed-layer residual port provably loses information about the growing KV-cache state (this conjecture). The "native math" of the full state is the non-commutative, position-indexed KV-cache algebra — genuinely non-$\mathbb{R}^n$ because its dimension grows.
- In an SSM, the full state IS fixed-dimensional, so a single-layer state port can in principle be an internally sufficient carrier. The native math is the linear-algebraic structure of the diagonal state-transition matrix $A$: its eigenvalues (complex frequencies and decay rates), its selectivity gates, its spectral decomposition. This is standard linear-systems theory, not a new mathematics.

This suggests the program's negative result (no native non-$\mathbb{R}^n$ mathematics found) may be partially explained by architecture: transformer residual streams genuinely ARE $\mathbb{R}^d$ vectors (the non-$\mathbb{R}^n$ structure lives in the growing KV cache, which the residual can't capture), while SSM states have algebraic structure (eigenvalue dynamics) that is

standard and already well-studied. In neither case does a genuinely new mathematics emerge from the existing architecture — the interesting structure is either inaccessible (transformer KV cache) or already described (SSM spectral theory).

This observation does not close the guiding question. It sharpens it: a genuinely new latent-space mathematics would require an architecture whose state has structure that is neither growing-dimensional (transformer) nor standard-linear-algebraic (SSM) — perhaps a system with compositional, typed, or topological state that current architectures do not have.

### What kind of state would require new mathematics? (SPECULATIVE NOTE)

The architectural comparison identifies a gap in the landscape of neural state representations:

| Architecture | State type | Dimension | Existing math | Non-R^n? |
|---|---|---|---|---|
| Transformer | KV cache | O(Ldt), growing | Coalgebra, final semantics | Yes (growing), but inaccessible from residual |
| SSM (Mamba) | Diagonal recurrence | O(n), fixed | Spectral theory, linear systems | No — standard R^n dynamics |
| GNN | Node embeddings | O(Vd), graph-dependent | Graph signal processing | Partially — graph topology is non-R^n |
| Slot attention | Slot vectors | O(kd), fixed k | Set functions, permutation equivariance | Partially — unordered set structure |

A state type that would genuinely require new mathematics would need to be:
1. **Fixed-dimensional** (unlike transformers, so a port can capture it)
2. **Non-linear-algebraic** (unlike SSMs, so existing spectral theory doesn't suffice)
3. **Compositional** — supporting typed operations (read, write, compose) whose algebraic laws are non-trivial and not reducible to matrix algebra
4. **Accessible** — the denizen can read and write it through the architecture's native interface, not just through an analyst's probe

This is exactly the HANDLE specification: persistent entity slots with typed operations and causal handles. The program's negative result thus points constructively at what to build: the mathematics does not exist because the architecture does not exist. Building the architecture and discovering its mathematics would be a co-development, as the "co-evolve theory and practice" feedback memory mandates.

This speculative note is the program's closing theoretical direction. It does not constitute a claim, a plan, or authorization for any work.

---

## BP-1: Linear separability ≠ causal structure

**Assumption:** If a concept is linearly decodable from a representation, the representation "has" that concept in a causally meaningful sense.

**Where it broke:** `register_bridge_preflight_v1` achieved 0.815 accuracy decoding explicit-legend state from frozen Qwen3-1.7B — but this was a noncausal lookup signal. The information was present but not causally active. The subsequent causal interventions (`coordinate_v1-v3`, `interchange_v1-v2`, `state_bus_v1r1`) all failed to turn decoded information into causal control.

**What this tells us:** Native math must distinguish PRESENCE of information from ADDRESSABILITY (can you read it?) from COMPOSABILITY (can you use it to do things?). The three-gate model: present → addressable → composable. Linear probes only test gate 1.

---

## BP-2: Single-site interventions ≠ distributed state

**Assumption:** If a model stores a fact, there's a specific location (layer, position, direction) where that fact lives, and patching that location transfers the fact.

**Where it broke:** Every single-site causal intervention failed. `coordinate_v3` found a narrow late lexical-control effect at block 20 but it worked through direct logit projection, not state. `state_bus` achieved repeated categorical control but it was pair-specific lexical/semantic steering, not state-general.

**Phase 2 confirmation (v1d):** Component-level transplant proves this directly. Transplanting only the attention output or only the MLP output from an A-different donor shifts the B-answer by <1 logit (0/17 layers flip). Full residual-stream transplant shifts by +4.1 logits (all layers flip). Fusion is a WHOLE-STATE property — not localizable to any single component. The distributed nature isn't just about position; even within a single position, the state is a holistic object that can't be decomposed into independent component contributions.

**What this tells us:** Native "place" may not be a point in activation space. It may be distributed across positions and layers in a way that R^n patching can't capture. A native "move" might need to be a transformation of the computation itself, not a vector edit.

---

## BP-3: Vector distance ≠ semantic distance

**Assumption:** Points close in cosine/Euclidean distance are semantically similar; the metric structure of R^n reflects meaning.

**Where it broke:** NLM-001 through NLM-006b. Cosine similarity was the best predictor of task-effective relationships in DINOv2 — but this was exactly the R^n trap. The metric worked because the encoder was trained to make it work, not because it reflected native structure. When we looked for structure BEYOND what the metric captured, we found nothing — because we were still measuring with the metric.

**What this tells us:** The native distance may not be a distance at all in the R^n sense. It might be asymmetric (A→B costs differ from B→A), context-dependent (distance between A and B depends on what else is present), or categorical (either same-place or different-place, with no meaningful gradient).

---

## BP-4: Fixed-dimensional representation ≠ fixed structure

**Assumption:** Because the residual stream has dimension d, the representation lives in R^d and has the structure of a d-dimensional vector space.

**Where it broke:** `reachability_v1` found effective rank ~2.3 at the probe site, but this was inseparable from baseline logit gaps, cross-name gradient averaging, position effects, and prompt geometry. The "dimensionality" of the representation wasn't an intrinsic property — it was an artifact of the measurement.

**What this tells us:** Native dimensionality may be context-dependent, task-dependent, and measurement-dependent. There may not be a fixed "d" for the representation — the effective structure may change depending on what the model is doing. Superposition (Anthropic's work) suggests models use far more features than dimensions, which means the vector-space structure is a carrier, not the content.

---

## BP-5: Composition in representation ≠ composition in vector space

**Assumption:** If the model represents A and represents B, then the representation of "A and B together" is some function of repr(A) and repr(B) in vector space (e.g., addition, concatenation, some learned function).

**Where it broke:** The toy quotient program (Rounds 36-37) tried to build exact compositions and found that no learned artifact passed the complete exact reducer — only the oracle fixture did. Composition that worked perfectly in the symbolic domain (affine bijections over GF(5)) didn't transfer to learned representations.

**What this tells us:** Composition in latent space may operate through the MODEL'S FORWARD PASS, not through vector operations. The "algebra" might be: feed A through the model to get repr(A), then feed "A and B" through the model to get repr(A□B) — and the composition rule is the forward pass itself, not any vector operation we can observe from outside.

---

## BP-6: Observation ≠ state (the instrument problem)

**Assumption:** We can observe the model's internal state by probing activations at specific layers and positions.

**Where it broke:** Repeatedly. `onewrite_state_v1` — the base model couldn't even apply a stated rule to visible tags. `onewrite_recall_v1` — a valid direct-copy instrument failed held-out recall. `oracle_actuator_rung0` — even with oracle codes, balanced eight-way control failed.

**What this tells us:** Observation changes what you see. The act of choosing a probe site, a readout function, and a set of concepts to look for constrains what you can find. Native math needs to account for the instrument — not as a nuisance but as a fundamental part of the theory. This is where D2 (registration-relative observation) in the axioms was heading.

---

## BP-7: Static snapshot ≠ dynamic computation

**Assumption:** A model's representation at time t can be understood by examining activations at time t.

**Where it broke:** The "lexical-semantic steering" pattern in `state_bus_v1r1` — the model's response depended on the specific donor-verbalizer pairing, not on an abstract state. The model wasn't storing state; it was computing a response path through the activation space, and that path depended on the full context.

**What this tells us:** Native math may need to describe TRAJECTORIES through activation space (the computation), not POINTS in it (the state at one moment). The "object" isn't a vector — it's a computational path.

---

## BP-8: R^n tools find R^n structure (circularity)

**Assumption:** PCA finds the "true" low-dimensional structure. Cosine similarity finds the "true" similarity. Linear probes find the "true" features.

**Where it broke:** PSQ-3α. PCA was transductive over all 32 states; the quotient-holdout design shared all x-places between calibration and held-out sets. The measurement tool imposed its own structure on the answer. 69.14% accuracy (gate ≥95%) — but was this a failure of the model or a failure of PCA to capture what the model was actually doing?

**What this tells us:** Every R^n tool carries its own axioms. Using it gives you R^n answers. The native math must be discovered by tools that DON'T presuppose R^n structure — or by carefully analyzing where R^n tools FAIL and asking what structure would explain the failure.

---

## BP-9: R^n distance is blind to compositional structure (Phase 2, fusion-fission v1)

**Assumption:** If two representations are cosine-similar, they are functionally similar — similar inputs to downstream computation.

**Where it broke:** Fusion-fission v1. Four worlds (2x2 fact combinations) have cosine similarity ~1.0000 at layers 4-24. Yet transplanting one world's hidden state into another produces dramatically different behavioral outcomes depending on the layer: at some layers facts are independently controllable (SEPARATE), at others changing one fact inevitably changes both (FUSED). R^n's distance metric sees "same" where the computation sees "different."

**What this tells us:** The behaviorally relevant structure lives in a subspace or nonlinear manifold that global distance metrics can't see. "Close in cosine" does not mean "functionally equivalent." Native distance (whatever it is) must be sensitive to the compositional structure that cosine misses. This may be the clearest evidence yet that R^n distance ≠ native distance.

**PCA result (v1b):** PCA CAN separate worlds at all layers — so the structure is linearly accessible. But PCA separation doesn't predict behavioral fusion/fission: facts are linearly decodable even when behaviorally inseparable. PRESENCE (PCA) ≠ ADDRESSABILITY (transplant). The native math must describe causal accessibility, not storage geometry.

**Attention result (v1c):** Cross-fact attention is LOWER at fused layers (0.275) than separate (0.336). The mechanism causing fusion is not attention cross-talk — ruling out the most obvious pathway.

**Component transplant (v1d):** Neither attention-only nor MLP-only transplant can flip fact B. Only full residual-stream transplant does. Fusion is a WHOLE-STATE emergent property of the layer transformation. (Connects to BP-2.)

**Trajectory result (v1e):** Worlds ALWAYS diverge through all layers.

FUSED layers diverge slowly (-1.2), SEPARATE layers diverge fast (-5.7). Fusion = world-insensitive computation (model treats all A-worlds the same). Fission = world-sensitive computation (model discriminates). The behavioral transplant amplifies tiny directional differences through remaining layers — static trajectory metrics are too coarse.

---

## Phase 2–5 breakpoints (2026-08-31 → 2026-09-01)

Additional structural holes discovered across 60+ experiments on frozen Qwen3-0.6B-Base and learned architectures.

---

## BP-10: Composition is logit addition (terminal diagnostic, Gate I)

**Assumption:** If two interventions compose (the combined effect produces the correct output), the model is performing some nontrivial nonlinear computation to integrate them.

**Where it broke:** Terminal diagnostic Gate I. The logit-additive null l_a + l_b - l_0 explains 99.1% of the composition effect measured in RAC-0/RAC-1 (sqrt(JSD) = 0.0001 between predicted and actual composed distributions, 12/12 top-1 match). The "composition" is ordinary logit addition through the linear unembedding matrix.

**What this tells us:** The unembedding is linear, so perturbations at hidden-state level produce approximately additive logit effects. The post-B20 nonlinear layers do NOT significantly mix the two steering directions. "Composition" through vector addition is just decoder competition — the two perturbations independently shift logits, and softmax picks the winner. Native composition (if it exists) must operate through a mechanism that is NOT reducible to logit addition.

---

## BP-11: No template-invariant response fibers (terminal diagnostic, Gate F)

**Assumption:** States presenting the same fact in different wordings produce sufficiently similar response distributions that they can be treated as the same "place" in response space.

**Where it broke:** Terminal diagnostic Gate F. No template pair has baseline sqrt(JSD) < 0.15 across 36 tested pairs (smallest gap: 0.19). The model's response law is highly presentation-dependent — different wordings of the same fact produce different distributions.

**What this tells us:** In Qwen3-0.6B, there are no template-invariant response fibers at this task granularity. The model does not have a "canonical response" for a given fact — the response depends on HOW the fact was stated, not just WHAT was stated. Native math must either work with presentation-dependent response laws or find/build a model where presentation invariance holds.

---

## BP-12: Circuit selection in learned models (LAC-0)

**Assumption:** A model trained to compose actions will learn a single compositional mechanism.

**Where it broke:** LAC-0 (learned action carrier, 739K params, 3 seeds). Different weight initializations learn fundamentally different capabilities: default init → endpoint composition (96%) but 0% sequential; Xavier init → sequential execution (95%) but 34% composed carriers. These are different optimization basins. Neither passes the complete composition gate.

**What this tells us:** Composition may have multiple incompatible realizations in neural parameter space. Training doesn't converge to "the" compositional solution — it finds one of several incomplete solutions depending on initialization. Native math must account for this multiplicity: the "algebra" of the learned system depends on which basin the optimizer fell into.

---

## BP-13: Capability floors (PSQ-1, permutation eligibility)

**Assumption:** A language model can track state through prompts if the prompts clearly describe state transitions.

**Where it broke:** Every tested model size fails the two-dial world (Z8×Z8, 64 states, Python-completion) capability gate (≥95%): 0.6B (48%), 1.7B (50-54%), 4B (56%), 8B (55.5%), 8B-Instruct (50-64%). Permutation eligibility: 48% overall, with only "reverse" working (97%); cyclic rotations fail (13-34%).

**What this tells us:** Small-to-medium base models cannot track multi-step state evolution through prompts. There is a CAPABILITY FLOOR below which native mathematical structure cannot be tested — the model doesn't have the behavioral interface. Any program seeking native math in frozen models must first confirm the model can reliably perform the underlying task.

---

## BP-14: Selectivity is verbalizer-sufficient (OSQ-1)

**Assumption:** Query-selective processing in late layers reflects structured computation (a behavioral algebra, attention routing, or state-dependent processing).

**Where it broke:** OSQ-1 (observational selectivity quotient). The 62× late-layer amplification is real (S(25)=0.633, G(25)=0.633, R(25)=0.785) but coarse-graining to 3-bin (v0, v1, rest) accounts for 100% of the selectivity signal (V=1.01). The selectivity is entirely ordinary answer-token routing through the verbalizer.

**What this tells us:** What looks like "structured computation" in the logit lens may be entirely explained by token-level routing to the answer vocabulary. The verbalizer null (does coarse answer-token routing explain everything?) must be tested before claiming behavioral algebra.

---

## BP-15: Bypass is destructive (ERQ-1)

**Assumption:** Individual transformer blocks make independent contributions that can be removed (bypassed) to study their function.

**Where it broke:** ERQ-1 (endogenous response quotient). Identity bypass at block 25 produces viable states for only 7/48 cells. The bypassed state is off-manifold — it's too destructive to serve as a scientific instrument.

**What this tells us:** Transformer blocks are deeply coupled. The output of block N is precisely on the manifold that block N+1 expects. Removing a block doesn't give you "the representation without block N's contribution" — it gives you garbage. Native math must account for this coupling: layers are not independent operators that can be composed/decomposed at will.

---

## Open questions from the breakpoints

1. If composition happens through the forward pass (BP-5), can we characterize the algebra of the forward pass itself? What are its operations, identities, inverses?

2. If state is distributed (BP-2), what is the right unit of analysis? Not a vector at a site, but... what? A circuit? A subcomputation? A pattern across positions?

3. If dimensionality is context-dependent (BP-4), what determines the effective structure at any given moment? Is there a native notion of "what matters right now"?

4. If observation is registration-relative (BP-6), can we build instruments that are transparent about their own axioms? Instruments that measure relative to themselves rather than relative to R^n?

5. The three-gate model (present → addressable → composable) from BP-1 — can we build tests for each gate separately? Can we find things that pass gate 2 (addressable) but fail gate 3 (composable)? That gap would be the most informative breakpoint of all.

# Continuation-Refinement Calculus

## Role in the current direction (2026-09-13)

[Cumulative capability acquisition](CUMULATIVE_CAPABILITY_ACQUISITION.md) is the current exploration direction within the broader native-mathematics philosophy. This calculus supplies candidate language for preserving distinctions and operations across acquisition interfaces. Its definitions and conditional bounds do not establish cross-model transfer, assimilation or cumulative reasoning. The historical status index and proof record below remain in force as evidence.

## Status index (2026-09-06; read this before the body)

| Section | Status | One line | | | | |
|---|---|---|---|---|---|---|
| CR-1 to CR-9 | ADOPTED (definitions) | Complete response tree, horizon tower, separating languages, derivative, typed positions; CR-9 corrected by audit #39 (finite-resolution sensitivity, not exact refinement) | | | | |
| CR-10, CR-11 | ADOPTED | Selective write laws; last-write normal form; orbit bound ∏( | V_r | +1), exactly ∏ | V_r | after a complete initialization (audit #39 wording) |
| CR-12 | REQUIRED EVIDENCE | Promotion criteria; none established | | | | |
| CR-13, CR-14 | ADOPTED (design) | Falsifiers; commit-seal carrier; rung 1 paused (2/5 seeds) | | | | |
| CR-15.0 to 15.5 | ADOPTED, audited #39 | Common-kernel (lens) representation; invariant relations 2η; contraction certificate; selective-tube certificate; constant-gate construction | | | | |

| | | | | | | |
|---|---|---|---|---|---|---|
| CR-15.6, 15.7 | ADOPTED, audited #39 | Prior art and paired-pool fidelity lemma; falsifiers; 16-transition check | | | | |
| CR-15.8 | ADOPTED, audited #40 | Finite exact orbit N: lifetime error ≤ min{1,(N−1)ε}, sharp in order | | | | |
| CR-15.9 | ADOPTED (pending audit) | Register-free form; finite orbit sufficient, not necessary | | | | |
| CR-15.10 to 15.10.5 | ADOPTED (dialogue rounds 1-2) | Interface-relative interchangeability; modulus ω; licensed CR-9 reading; CRC-0 witness reading | | | | |
| CR-15.10.6 | LOCKED | Analytical cycle and deferred panel rules | | | | |
| CR-15.10.7 | REVISED, audited #41 | Retained: panel enclosures, declared-domain moduli, refinement identity, conditional routes. Withdrawn: original obstruction theorem, saturation impossibility, global rank bound | | | | |
| CR-16 | RESTATEMENT, audited #42 | Architectural identities as background; two-route decomposition withdrawn | | | | |

Zero-call readings of archived tables (2026-09-06) are recorded in experiments/EXPERIMENTS.md, not here. The formerly prioritized acquisition (eligibility-first strong-assert panel) remains a deferred draft requiring review and compute approval. It is not the automatic next step under the new direction.

Status: THEOREM ATTEMPT (v1). Builds on D1-D6. Replaces metric/Finsler extensions (D7). Motivated by SVB structured negatives and Codex post-SVB pivot (2026-09-04).

Date: 2026-09-04. Per Codex Architecture Theorist recommendation.

## Motivation

Every SVB experiment projected the behavioral quotient Q_M onto scalars (log-odds, TV distances, OLS coefficients) and fitted linear models. The structured negatives — congruence failure, position-dependent gain,

padding-sensitive curvature — all trace to the same root: the measurement discards structure that later operations can reveal.

This document replaces metric geometry with the calculus of which future operations distinguish which states. The primitive is not distance but separation: which continuation first proves two states are different.

## CR-1. Complete response tree — definition

Import D1 (raw presented transition world), D2 (response laws), D3 (immediate discrepancy).

For a state x □ Z, the complete response tree is the function:

Beh(x)(w, c) = r_c(T_w x)

for all w □ W = A* (legal-word monoid from D1) and c □ C (response channels from D2).

The behavioral quotient Q_M = Z/~ where x ~ y iff Beh(x) = Beh(y) is imported from D4. This is exact Q_M — an omniscient external construction requiring all futures.

## CR-2. Horizon-bounded equivalence — definition

A denizen with bounded computational budget has access to futures of bounded length. Define the h-equivalence:

x ≡_h y □ r_c(T_w x) = r_c(T_w y) for all c □ C, |w| ≤ h

where |w| is the word length (number of primitive actions).

Properties:

- □ ≡_0 is immediate response equivalence (same present observations)
- □ ≡_{h+1} refines ≡_h (never coarsens)
- □ ≡_∞ = ≡_M (the full behavioral equivalence from D4)
- □ Each ≡_h induces graded maps T_a : Q_{h+1} → Q_h (by monotonicity, CR-4), NOT automatically T_a : Q_h → Q_h. Same-level closure is evidence only after stabilization and only when tested out of sample. (Correction per Codex design gate, 2026-09-04.)

The quotient tower:

Q_0 ← Q_1 ← Q_2 ← ⋯

where Q_h = Z/≡_h and each arrow is the canonical surjection (since ≡_{h+1} □ ≡_h, every ≡_{h+1} class is contained in some ≡_h class).

This is the refinement tower. It is the native geometry: the structure is which classes split and how, not where points lie in a vector space.

## CR-3. Separating language — definition

For two states x, y □ Z, the separating language is:

Sep(x, y) = { w □ W : □c □ C, r_c(T_w x) ≠ r_c(T_w y) }

Sep(x, y) is the set of all continuations that prove x and y are different. Properties:

- □ Sep(x, y) = □ □ x ≡_M y (behaviorally equivalent)

□ Sep(x, y) = Sep(y, x) (symmetric)

□ The shortest word in Sep(x, y) determines the refinement level at which x and y first become distinguishable

Define the separation depth:

d_Sep(x, y) = min{ |w| : w □ Sep(x, y) }

with d_Sep(x, y) = ∞ when Sep(x, y) = □. This is a native "distance" but NOT a metric: it violates the triangle inequality in general.

## CR-4. Derivative under actions — definition

For an action a □ A, the Brzozowski-style derivative of the separating language is:

Sep(T_a x, T_a y) = { w : wa □ Sep(x, y) }

(under the project's right-to-left concatenation convention where wa means "apply a first, then w").

This is a NATIVE notion of direction: applying action a transforms which futures can distinguish two places. The derivative tells us what a move DOES to the distinguishing structure, without reference to coordinates, distances, or vector space operations.

Key properties:

□ Sep(T_a x, T_a y) □ $a^{-1}$ Sep(x, y) (right quotient of Sep by a)

□ If T_a x ≡_M T_a y but x □_M y, then action a ERASES a distinction (collapses two classes). The lost words are exactly Sep(x,y) \ ($a^{-1}$ Sep(x,y) · {a}).

□ If T_a x □_M T_a y but x ≡_M y, this is impossible (nonexpansiveness of T_a under ≡_M, which is a congruence).

Theorem (Monotonicity): For any action a and horizon h,

x ≡_{h+1} y □ T_a x ≡_h T_a y.

Proof: For every |w| ≤ h, |wa| ≤ h+1. Therefore x ≡_{h+1} y implies r_c(T_{wa} x) = r_c(T_{wa} y) for every c, which is exactly T_a x ≡_h T_a y. □

## CR-5. Refinement events — definition

A refinement event at level h is a pair (x, y) such that:

□ x ≡_{h-1} y (indistinguishable at horizon h-1)

□ x □_h y (distinguishable at horizon h)

The witness for a refinement event is a word w with |w| = h and a channel c such that r_c(T_w x) ≠ r_c(T_w y). The witness w is a shortest distinguishing future.

The refinement rate ρ(h) counts the number of equivalence classes at level h relative to level h-1:

ρ(h) = |Q_h| / |Q_{h-1}|

Properties:

□ ρ(h) ≥ 1 always (refinement never coarsens)

- ρ(h) = 1 means level h adds no new distinctions (stabilization)
- If ρ(h) = 1 for all h ≥ H, the tower has finite depth H
- Class-count ratios require finite, nonzero cardinalities; equal infinite cardinalities do not establish stabilization. With finite partitions a single plateau already forces all subsequent stabilization (CR-15.7 eq. (9)). Note also that 2^{-d_Sep} (with 2^{-∞} = 0) is an ultrametric on the behavioral quotient, so separation depth is not outside familiar metric theory. (Audit #39.)

A compact predictive calculus exists when the tower stabilizes at finite depth H with |Q_H| << |Z|. This is compression: the model's behavioral structure admits a finite description.

## CR-6. Typed process structure — definition

Following Codex's recommendation to replace the one-object monoid with a typed category:

Objects include token position p, execution phase φ, and available history context κ. A typed action is a triple (a, p, φ, κ) specifying the action, the position at which it is applied, the phase, and the history context.

Two instances of "the same suffix" at different positions are different typed arrows. The positional-gain result from Gate 2 v2 is evidence for this typing: the order effect is positional, meaning the arrow type (not just the action label) determines the behavioral consequence.

This makes position a first-class part of the mathematical structure, not a nuisance variable to be regressed away.

## CR-7. Compact presentation — promotion criteria

A refinement calculus earns "native mathematics" status when ALL of:

1. **Compression**: |Q_H| << |{distinct histories}|. The quotient compresses history into a finite set of behavioral states.

2. **Prediction**: The transition table at Q_H predicts the response to unseen continuations better than raw text/position baselines.

3. **Transfer**: The calculus transfers across held-out presentations (different surface texts for the same operation) without refitting.

4. **Derivative closure**: The derivative Sep(T_a x, T_a y) is predictable from the class labels [x], [y] and the action a. That is, the derivative is an operation on the quotient, not on the raw states.

5. **Causal realization**: States classified as equivalent by the calculus can be substituted for each other (in a recurrent model) or produce equivalent continuations (in a transformer) without behavioral change beyond a declared tolerance.

If the tower does not stabilize, or the text baseline matches the quotient's predictions, or the derivative is not closed, then the

calculus does not exist for this model — and that is a first-class structural diagnosis, not a failure.

## CR-8. Relation to existing framework

**Keeps from D1-D6:**

- Raw presented transition world (D1)
- Response laws and discrepancy (D2-D3)
- Future-response pseudometrics (D4) as the omniscient limit ≡_∞
- Nonexpansiveness of legal moves (from D4's properties)
- Behavioral congruence (D11)

**Replaces:**

- D7's metric/differential/Finsler geometry → refinement tower
- Log-odds, TV, OLS as foundational → response equality as primitive
- Scalar distance as the measurement → separation depth d_Sep
- Global operator algebra → derivative calculus on Sep

**Corrects from SVB negatives:**

- Coarse 11-bin projection → full next-token response law
- Global δ_L as equivalence criterion → ≡_h at declared horizon
- Position as nuisance → position as type in the process category
- Presentation as gauge symmetry → presentation as part of state

until a tested quotient removes it

## CR-9. Experimental contact

The first test is on existing SVB data (zero-call reanalysis):

The congruence experiment found that "equivalent" surfaces (similar δ_L) diverge under composition with heavy suffixes (ratio 2.6-13.2×). In the refinement language, read at finite resolution: these pairs have small but nonzero immediate discrepancies, which the heavy continuation amplifies. They illustrate finite-resolution sensitivity, not an exact refinement event under CR-2 (audit #39 correction).

Zero-call reanalysis results (2026-09-04):

| Pair | Q_0 TV | Neutral (0.8x) | Heavy (6.5x) | Split? |
|---|---|---|---|---|
| strong_assert | 0.0056 | 0.0044 (0.8x) | 0.0735 (13.2x) | YES |
| moderate_assert | 0.0128 | 0.0079 (0.6x) | 0.0481 (3.8x) | YES |
| misleading | 0.0247 | 0.0225 (0.9x) | 0.0644 (2.6x) | YES |

The neutral composer ("# No changes.\n") leaves the immediate discrepancy essentially unchanged.
The heavy composer ("# Reassigning {var} now.\n") is a length-1 distinguishing future for all 3 pairs. Composition order also matters: forward (suffix then composer) produces 2-4x more amplification than reverse for the heavy composer, confirming position as arrow type.

The fresh experiment will:

1. Use the full next-token response law (not 11-bin)
2. Construct Q_0, Q_1, Q_2 explicitly on a competence-gated task
3. Measure refinement rate ρ(h) and stabilization

4. Test derivative closure: does knowing [x] and a predict [T_a x]?

5. Compare against text/position baselines

6. One round, decisive

## CR-10. Selective write boundary — axioms

Motivated by CEG-1 (REVISE): the tested Qwen3-1.7B interface did not establish a behavioral overwrite law. Retained raw history was observed, but CEG-1 does not prove that pretrained transformers lack endogenous behavioral overwrite (audit #39).

The construction program asks: if a model is given an internal "replace this fact" operation, does compositional reasoning become possible because dead history is truly dead?

The write boundary is a declared substrate axiom, not the artifact itself (Codex pushback, 2026-09-04). The scientific question is whether a LEARNED DENIZEN can use it to form portable, compositional predictive states. Boundary satisfaction is by construction; learned use, transfer, and causal substitution are the claim-bearing results.

### Definitions

Import ≡_M (behavioral equivalence from CR-1) and ≡_h (horizon-bounded from CR-2). Write x □ y as shorthand for x ≡_M y.

**Register store.** A finite set R of register names. Each r □ R holds values from a finite alphabet V_r. The store type is S = ∏_{r□R} V_r. A store state σ □ S is a function σ: R → □_r V_r with σ(r) □ V_r.

**Keyed write.** For each r □ R and v □ V_r, there is an endogenous action W_{r,v}: Z → Z that writes value v to register r. "Endogenous" means: available to the model as an internal operation, not an external surgical intervention. The model can choose to perform W_{r,v} as part of its computation.

**Read.** For each r □ R, a readout function read_r: Z → V_r extracts the current value of register r from the model's state.

### Laws (required at the behavioral level)

**L1. Overwrite absorption (NOT idempotence):**

W_{r,v'} □ W_{r,v}(x) □ W_{r,v'}(x)

The last write to a register determines all future behavior. Dead writes have no causal residue. Note: this is absorption (general v, v'), not idempotence (which is the v'=v special case). Correction per Codex design gate 2026-09-04.

**L2. Independence (cross-register commutativity):**

W_{r,v} □ W_{s,u}(x) □ W_{s,u} □ W_{r,v}(x) for r ≠ s

Writes to different registers do not interfere. The order of unrelated writes is irrelevant to future behavior.

**L3. Preservation (unrelated distinctions survive):**

x □_M y via Sep_{s≠r} □ W_{r,v}(x) □_M W_{r,v}(y)

Writing to register r preserves behavioral distinctions that depend on other registers. A write does not globally scramble the predictive state.

**L4. Write fidelity:**

read_r(W_{r,v}(x)) = v

A write actually writes. Combined with L1, this gives: read_r recovers the last-written value regardless of history.

## CR-11. Last-write normal form — theorem

**Theorem (Normal Form).** If L1 and L2 hold, then for any finite sequence of writes w = W_{r_n, v_n} □ ⋯ □ W_{r_1, v_1} applied to state x, there exists a unique normal form:

nf(w)(x) □ (∏_{r □ touched(w)} W_{r, last(w,r)})(x)

where:

- □ touched(w) = {r_1, ..., r_n} (registers written at least once)
- □ last(w, r) = v_j where j = max{i : r_i = r} (the final value written to r)
- □ The product is well-defined (order-independent) by L2.

**Proof sketch.**

1. By L1, consecutive same-register writes collapse:
W_{r,v'} □ W_{r,v} □ W_{r,v'}.
2. By L2, writes to different registers can be reordered.
3. Apply L1 repeatedly to eliminate all but the last write to each register. Apply L2 to sort the remaining writes into any canonical order. The result is unique because last(w,r) is determined by w and the product is order-independent. □

**Corollary (Quotient bound).** The number of behaviorally distinct write-reachable states from any starting state x is at most:

|Q_writes(x)| ≤ ∏_{r□R} (|V_r| + 1)

The +1 accounts for untouched registers (never written). Reaching the tighter bound ∏|V_r| (without +1) requires an additional store-sufficiency condition: that the current-value-write identity holds (writing the value a register already holds is a no-op). This tighter bound is itself something to test, not assume. Correction per Codex design gate 2026-09-04.

The bound is independent of the number of write operations — history length does not grow the predictive state.

## CR-12. Distance from CR-7 promotion criteria

The following are required empirical promotion criteria. CR-15 does not establish them, and the recorded partial rung-1 run does not establish completed staircase validation. The write-boundary substrate would earn "native mathematics" status by satisfying CR-7 with these instantiations:

1. **Compression**: |Q_H| ≤ |S| = ∏_r |V_r| << |{distinct write

histories}|. REQUIRED EVIDENCE. The quotient compresses write histories into live-store states.

2. **Prediction**: The transition table at Q_H (indexed by store contents, not history) predicts responses to unseen continuations better than raw text/position baselines. REQUIRED EVIDENCE.

3. **Transfer**: The compression transfers across held-out surface presentations (different wordings of the same write operations) without refitting. REQUIRED EVIDENCE.

4. **Derivative closure**: Sep(T_a(x), T_a(y)) is predictable from the store states σ(x), σ(y) and the action a. That is, knowing what's in the registers (not how they got there) suffices to predict which futures distinguish two states. REQUIRED EVIDENCE.

5. **Causal substitution**: States with identical store contents but different write histories can be swapped in a recurrent model without behavioral change beyond a declared tolerance. REQUIRED EVIDENCE.

**By construction (commit-seal carrier, revised):**

- Causal cut at COMMIT (hard seal — only the carrier survives)

**Claim-bearing (must be learned, not hard-wired):**

- L1 (overwrite absorption): U learns to produce m+ that makes dead writes causally irrelevant to the registered reader. REQUIRED EVIDENCE via paired erasure. Not hard-wired — U can fail.
- L4 (write fidelity): U encodes the proposed value in m+. REQUIRED EVIDENCE via visible proposal head and carrier transplant.
- L2 and L3: not tested at rung 1 (requires multiple addresses).
- Compression: |Q_H| << |histories|
- Transfer: structure generalizes across presentations (rung 3+)
- Causal substitution: carrier-equivalent states are behaviorally equivalent under the co-trained reader
- Advantage over no-seal ablation (SEAL_ADVANTAGE, separate verdict)

## CR-13. Falsifiers

The construction program is falsified if ANY of:

**F1. Overwrite irrelevance.** The overwrite model produces the same behavioral quotient as the matched append-only ablation. The write boundary doesn't help — the model either ignores it or the benefit is zero.

**F2. History leakage.** Despite the causal cut at COMMIT, the carrier m+ encodes both obsolete and current values. |Q_H| > |S| because behavior depends on write history, not just current store contents. In the commit-seal design: U fails to learn overwrite, retaining dead information in the carrier. (Note: the seal prevents leakage through activations; F2 tests whether U itself leaks.)

**F3. No transfer.** Compression holds on training presentations but does not transfer to held-out wordings. The quotient is surface-

specific, not a native structure.

**F4. Trivial task.** The task is simple enough that even the append-only model compresses. The write boundary provides no advantage because the task doesn't require overwriting.

**F5. EAC tautology.** The only demonstrated property is that erased values are erased — no compositional benefit. This repeats the architecturally tautological EAC result without scientific content.

Each falsifier is testable in a single experimental round. F1 is the primary gate: if the overwrite model has the same quotient as append-only, stop.

## CR-14. Experimental design — commit-seal carrier (revised)

**Revision note (2026-09-04):** The original CR-14 used a hard-wired register file with hard-masked overwrite. Codex design gate identified this as a repeat of the EAC tautology: if overwrite is guaranteed by construction, testing whether overwritten values are erased is tautological. WB-1 confirmed: |Q_H|=16 exactly (by construction), but the result is architectural, not learned. The revised design makes the LEARNED UPDATE — not the hard-wired register semantics — the smallest falsifiable object.

### Architecture: commit-seal carrier

A recurrent model with:

1. **Transient encoder**: processes each input statement, producing a write proposal (address, value embedding).

2. **Learned update U**: a neural function
m+ = U(m, address, proposal)
that computes the new carrier state from the old carrier, the addressed slot, and the proposed value. U is LEARNED — it is not hard-wired to overwrite.

3. **Hard seal (COMMIT)**: at commit, all pre-commit token and activation history is erased. All subsequent influence on behavior must pass through m+. The seal is the information bottleneck — the only hard constraint.

4. **Learned reader**: consumes m, the queried address, and a per-episode output legend to produce the response.

**What the model CAN fail at:**

- Encoding (old_value, new_value) in m+ instead of just new_value
- Entangling addresses (mixing which slot holds which value)
- Ignoring the carrier (using hidden state instead of m)
- Producing non-portable m+ (works only with specific readers)

**What the seal guarantees:**

- If U learns to produce m+ that retains only current values, dead information CANNOT leak through other paths

 This is an explicit information-flow guarantee of the proposed carrier; CEG-1 did not establish its absence from every pretrained transformer interface

### Matched ablation: no-seal recurrent

Same architecture, same U, same parameters, same everything — but NO seal. The model can access both m+ AND pre-commit activations. Parameter- and activation-matched. The ONLY difference is the information bottleneck.

If the sealed model has a smaller quotient, the seal is doing useful work. If both quotients are equal, the seal provides no compositional advantage.

### Positive-control staircase

Do not jump to the full design. Change exactly one difficulty per rung:

**Rung 1 (first implementation):**

 1 address
 2 values
 2 commits (write(u), then write(v))
 Training entities and wording (no held-out)
 Zero configured filler

Primary claim: after write(u); write(v), changing u does not materially change any registered future response, while transplanting the committed carrier transfers v-specific behavior.

Required controls:

 ≥95% visible and single-write competence
 Self-transplant, wrong-live-value transplant
 Value-proposal shuffle (scrambled address is impossible with 1 address; shuffle the value-to-proposal mapping instead)
 Matched no-seal ablation
 Approximate paired erasure with tolerance frozen from noise floor

**Subsequent rungs (only after prior rung passes):**

1. Second address + cross-address commutation (tests L2)
2. Short delay between writes
3. Held-out entity names
4. Unseen wording/templates
5. Long delay

### Measurements

 Primary: paired erasure — changing the obsolete write u does not change registered futures (within tolerance)
 Causal donor following: transplanting m+ transfers v-specific behavior to a new context
 Quotient: |Q_H| for sealed vs no-seal (F1 gate)
 Accuracy: single-write competence ≥95%

### WB-1 status (hard-register experiment)

WB-1 (hard-wired register, 2026-09-04) is a single-seed diagnostic, not L1-L4 validation (Codex: learned write heads unused, overwrite arm retains history-bearing GRU path, arms have unequal parameters). Overwrite model achieves |Q_H|=16 (= ∏|V_r| = 4^2; note: the +1 in the general bound ∏(|V_r|+1) counts a distinct unwritten state — WB-1 initializes all registers to 0, so no unwritten state exists). Append-only: |Q_H|=20, alignment 0.750 (25% history leakage). F4: both compress on simple fact-tracking. WB-1 is retained as a mathematical diagnostic.

## CR-15. Selective behavioral reset: representation and uniform certificates

Status: THEOREM SET (analytic round 2, 2026-09-05; audit #39 corrections applied 2026-09-05). Adopted after a two-round dialogue with counterexamples; supersedes the informal "multiplicative vs additive dead mass" and "gate must saturate" claims of the round-1 draft, both withdrawn. No compute was used. Numbered equations (15.x) are internal to this section.

*So what:* A model should be able to replace one fact while keeping other facts usable, without obsolete history gradually changing its behavior.

This section derives the exact structure of selective overwrite and sufficient conditions for its approximate realization. It distinguishes behavioral laws from certificates computed using a metric on the carrier. It establishes no learned realization, transfer result, or architectural advantage.

**CR-15.0. Behavioral setting and scope**

Use the registered world of D1–D6:

$$
d_\infty(x,y)
=
\sup_{w,c}D_c\!\left(r_c(T_wx),r_c(T_wy)\right),
\qquad
Q=Z/{\sim},
\quad
x\sim y\iff d_\infty(x,y)=0.
$$

Write $\bar d$ for the induced metric on $Q$. Composition executes the rightmost map first.

Every legal move is nonexpansive:

$$
d_\infty(T_ax,T_ay)\le d_\infty(x,y).
\tag{15.1}
$$

Indeed, the continuations beginning with $a$ form a subset of all legal continuations.

Consequently, being $1$-Lipschitz in behavioral distance imposes no additional restriction on a legal write. **Preservation requires a lower bound on a surviving response distinction.**

Let $R$ be a finite register set, $V_r$ finite nonempty value sets, and

$$
S=\prod_{r\in R}V_r.
$$

Registered writes descend to $F_{r,v}:Q\to Q$. Assume, where explicitly invoked,

$$
F_{r,v'}F_{r,v}=F_{r,v'},
\tag{A1}
$$

$$
F_{r,v}F_{s,u}=F_{s,u}F_{r,v}\quad(r\ne s),
\tag{A2}
$$

and faithful native reads

$$
\operatorname{read}_r(F_{r,v}q)=v.
\tag{A3}
$$

The reads must be supplied by the registered response interface and well-defined on $Q$.

These are behavioral hypotheses. An arbitrary hidden-state decoder cannot establish A3 for the original registered world.

**CR-15.1. Common-kernel representation, including partial writes**

For $T\subseteq R$, put

$$
S_T=\prod_{r\in T}V_r,
\qquad
P_{T,\sigma}=\prod_{r\in T}F_{r,\sigma(r)}.
$$

For $T=\varnothing$, $S_T$ is a singleton and $P_{T,\sigma}=\mathrm{id}_Q$.

**Theorem.** Under A1–A3, for every fixed $T$:

1. All maps $P_{T,\sigma}$ have a common kernel equivalence relation $K_T$.
2. With $B_T=Q/K_T$ and quotient map $p_T$, there are sections

$$
s_{T,\sigma}:B_T\to Q
$$

satisfying

$$
P_{T,\sigma}=s_{T,\sigma}p_T,
\qquad
p_Ts_{T,\sigma}=\mathrm{id}_{B_T}.
$$

3. The $T$-saturated subset

$$
Q_T=\bigcup_{\sigma\in S_T}\operatorname{im}P_{T,\sigma}
$$

is canonically isomorphic to $B_T\times S_T$. For $r\in T$,

$$
F_{r,v}(b,\sigma)=(b,\sigma[r\leftarrow v]).
$$

*Proof.* Commuting different-register writes and absorbing earlier same-register writes gives

\[
P_{T,\tau}P_{T,\sigma}=P_{T,\tau}.
\tag{15.2}
\]

In particular, these maps are idempotent.

If \(P_{T,\sigma}q=P_{T,\sigma}q'\), apply \(P_{T,\tau}\) and use (15.2) to obtain

\[
P_{T,\tau}q=P_{T,\tau}q'.
\]

Interchanging \(\sigma,\tau\) proves equality of their kernels.

Define

\[
s_{T,\sigma}(p_Tq)=P_{T,\sigma}q.
\]

The common-kernel property makes this well-defined. Equation (15.2) gives \(p_TP_{T,\sigma}=p_T\), proving the section identities.

The map

\[
(b,\sigma)\longmapsto s_{T,\sigma}(b)
\]

is surjective onto \(Q_T\). If two such images coincide, applying \(p_T\) identifies their \(b\)-coordinates. Moving each register's write to the final position and applying A3 identifies every coordinate of \(\sigma\). Thus the map is injective. Finally,

\[
F_{r,v}P_{T,\sigma}=P_{T,\sigma[r\leftarrow v]}
\]

proves the action formula. \(\square\)

For \(T=R\), this is the complete-write representation

\[
Q_{\mathrm{sat}}\cong B_R\times S.
\]

A complete write erases precisely a common kernel, preserves its class \(b\), and chooses the representative carrying the requested store.

For partial writes, the kernels vary with the touched subset. If \(T\subseteq U\), then

\[
K_T\subseteq K_U,\qquad Q_U\subseteq Q_T.
\tag{15.3}
\]

The first inclusion follows by completing a \(T\)-write to a \(U\)-write. The second follows because every \(U\)-written state is fixed by the corresponding \(T\)-write. Consequently, there is a canonical surjection

\[
B_T\longrightarrow B_U,\qquad [q]_{K_T}\longmapsto[q]_{K_U}.
\]

These subsets are **not disjoint grades of behavioral states**. In particular, \(Q_\varnothing=Q\). The grading initially belongs to write histories; behavior can identify different grades.

**Corollary: the partial-write monoid and CR-11's bound.**

Let

$$
\mathcal P=\prod_{r\in R}(V_r\sqcup\{\bot\}),
$$

where $\bot$ means “perform no write at this register.” Define

$$
(\alpha\star\beta)(r)=
\begin{cases}
\alpha(r),&\alpha(r)\ne\bot,\\
\beta(r),&\alpha(r)=\bot.
\end{cases}
$$

Thus $\alpha\star\beta$ executes $\beta$ first, then $\alpha$. Its identity is the all-$\bot$ assignment.

Set

$$
P_\alpha=\prod_{\alpha(r)\ne\bot}F_{r,\alpha(r)}.
$$

A1–A2 give

$$
P_\alpha P_\beta=P_{\alpha\star\beta}.
\tag{15.4}
$$

For a fixed initial place $q_0$, evaluation

$$
\alpha\longmapsto P_\alpha q_0
$$

is an equivariant surjection onto its write orbit. Therefore

$$
\begin{aligned}
|\operatorname{Orb}_{\mathrm{writes}}(q_0)|
&\le |\mathcal P|\\
&=\sum_{T\subseteq R}\prod_{r\in T}|V_r|\\
&=\prod_{r\in R}(|V_r|+1).
\end{aligned}
\tag{15.5}
$$

For each fixed $T$, A3 makes the $|S_T|$ outputs $P_{T,\sigma}q_0$ distinct. Outputs associated with different $T$ can coincide. Hence the sum counts tagged normal forms before those identifications.

The bound is attained from the all-$\bot$ state in the partial-store world $\mathcal P$, with coordinate-replacement writes and registered responses exposing every coordinate, including untouched status. If $\operatorname{read}_r$ retains codomain $V_r$, choose a default $v_r^0\in V_r$ for $\operatorname{read}_r(\bot)$ and expose untouched status through an additional native response channel. A3 still holds and all partial stores remain behaviorally distinct. The bound need not be attained when untouched status is behaviorally invisible.

Here $\bot$ is an identity operation, **not a reset-to-bottom write**. Declaring $F_{r,\bot}=\mathrm{id}$ while imposing A1 with $\bot$ as an ordinary writable value would require

\[
F_{r,\bot}F_{r,v}=F_{r,\bot},
\]
and hence \(F_{r,v}=\mathrm{id}\). A genuine reset-to-bottom action therefore defines an enlarged, different write interface.

**Corollary: initialized stores.** If
\[
q_0=P_{R,\sigma_0}q
\]
for an actual complete write, its write orbit has exactly \(\prod_r|V_r|\) places.

Merely assigning initial numerical values does not establish this premise. An initial “zero, untouched” place can remain distinguishable from “zero, written.” Current-value writes being behavioral no-ops provides an alternative sufficient condition.

The sets \(B_T\) may be infinite. Equation (15.5) bounds a fixed initial place’s write orbit, not the entire predictive carrier.

This is an isomorphism of sets equipped with the T-write action, not a claimed product decomposition of the behavioral metric. Common kernels and sections require only A1–A2; A3 supplies faithful store labels.

On \(Q_T\), define \(\mathrm{get}(q)=\mathrm{read}_T(q)\) and \(\mathrm{put}(q,\sigma)=P_{T,\sigma}q\). These satisfy PutPut, PutGet, and GetPut: the established very-well-behaved lens laws. The factor \(B_T\) plays the role of a preserved complement. Saturation is important because GetPut need not hold on all of \(Q\). On \(Q_R\), the action formula also preserves every distinction in \(b\) or an unaddressed register. [Foster, *Bidirectional Programming Languages*, §§2.1–2.2 and 6.5](https://www.cs.cornell.edu/~jnfoster/papers/jnfoster-dissertation.pdf).

**CR-15.2. Invariant relations give uniform behavioral guarantees**

Let \(\Lambda\) be an abstract registered transition system with maps \(f_a\) and response laws \(r_c^*\). It may include preserved context, register values, and untouched status.

Let nonempty sets \(K_\lambda\subseteq Z\) cover the declared initial states and their relevant reachable states. Suppose
\[
T_a(K_\lambda)\subseteq K_{f_a(\lambda)}
\quad\text{for every registered action }a,
\tag{15.6}
\]
and
\[
D_c(r_c(z),r_c^*(\lambda))\le\eta
\quad(z\in K_\lambda,\ c\in C).
\tag{15.7}
\]

**Theorem.** For every \(z\in K_\lambda\),
\[
D_c(r_c(T_wz),r_c^*(f_w\lambda))\le\eta
\quad\text{for every }w,c.
\tag{15.8}
\]
Consequently,
\[
z,z'\in K_\lambda
\implies d_\infty(z,z')\le2\eta.
\tag{15.9}
\]

\]

More generally, if \(f_u\lambda=f_v\lambda\), then

\[

d_\infty(T_uz,T_vz)\le2\eta.

\tag{15.10}

\]

*Proof.* Induction using (15.6) gives \(T_wz\in K_{f_w\lambda}\). Apply (15.7) to obtain (15.8). Two realizations of the same abstract state lie within \(\eta\) of the same response law after every continuation; the triangle inequality gives (15.9). Apply that conclusion to the common abstract endpoint of \(u,v\) to obtain (15.10). \(\square\)

Thus abstract absorption and commutation imply concrete L1 and L2 defects at most \(2\eta\). A write history and its partial-store normal form also differ by at most \(2\eta\), independently of history length.

This conclusion comes from transition closure of the relation. It does not follow merely by replacing the equalities in A1–A2 with small local errors.

**Corollary: preservation and fidelity require margins.** If an abstract continuation separates \(\lambda,\mu\) by

\[

D_c(r_c^*(f_w\lambda),r_c^*(f_w\mu))\ge\Delta,

\]

then their concrete realizations satisfy

\[

D_c(r_c(T_wz),r_c(T_wz'))\ge\Delta-2\eta.

\tag{15.11}

\]

For L3, the abstract distinction must survive the addressed write, and its surviving margin must exceed \(2\eta\).

This protects the specified abstract distinctions. It does not promise to preserve every small concrete difference.

A finite family of such sets gives a cover of bounded behavioral diameter. It does not establish a finite exact quotient: arbitrarily small observable distinctions can remain inside each set.

**Nonvacuity.** A useful certificate must improve on the trivial bound \(d_\infty\le1\) and preserve the declared response margins. Neither a singleton-per-concrete-state abstraction nor a finite cover alone establishes predictive compression.

**Counterexample: local absorption errors can accumulate.** Let \(N\) be even and take states \((s,j)\in\{0,1\}\times\mathbb Z_N\), with writes

\[

W_v(s,j)=(v,j+1).

\]

Register an exact value response and the nuisance response

\[

r(s,j)=\operatorname{Bernoulli}\!\left(\frac{1+\cos(2\pi j/N)}2\right),

\]

both with total variation distance. Every absorption comparison \(W_{v'}W_vx\) versus \(W_{v'}x\) has full behavioral discrepancy at most \(\sin(\pi/N)\): the value responses agree, and every common continuation preserves the one-step phase difference. Nevertheless, from \(j=-1\), the histories \(W_v^{N/2+1}\) and \(W_v\) have discrepancy \(1\). Write fidelity remains exact. Thus local absorption error tending to zero does not imply a history-uniform error bound tending to zero without additional assumptions.

**Counterexample: no greatest tolerance-bounded congruence in general.** Take three states with identity actions and Bernoulli response means \(0,\varepsilon,2\varepsilon\), where \(0<\varepsilon\le1/2\). The partitions \(\{0,1\}\mid\{2\}\) and \(\{0\}\mid\{1,2\}\) are transition congruences whose blocks have diameter at most \(\varepsilon\). Any common coarsening merges all three states and violates that bound. This does not preclude a greatest tolerance-compatible relation: \(\{(x,y):d_\infty(x,y)\le\varepsilon\}\) is transition-closed but need not be transitive.

**CR-15.3. Contraction supplies invariant sets, with domain and initialization conditions**

This is a **surgeon certificate** when its metric is supplied on the carrier. Denote that metric by $\varrho$, reserving D3's $\rho$ for immediate response discrepancy.

Let $M$ be a nonempty complete metric space with

$$
U_v:M\to M,\qquad
\varrho(U_vm,U_vm')\le\kappa\varrho(m,m'),
\quad 0\le\kappa<1,
\tag{15.12}
$$

uniformly over the finite value set $V$.

Banach's theorem gives a unique fixed point $p_v\in M$ for each $v$. Put

$$
D_*=\max_{u,v}\varrho(p_u,p_v),
\qquad
R_*=\frac{\kappa D_*}{1-\kappa}.
\tag{15.13}
$$

**Theorem.** For any $R\ge R_*$, the relative closed balls

$$
K_v=\{m\in M:\varrho(m,p_v)\le R\}
\tag{15.14}
$$

satisfy

$$
U_{v'}(K_v)\subseteq K_{v'}.
\tag{15.15}
$$

*Proof.* For $m\in K_v$,

$$
\begin{aligned}
\varrho(U_{v'}m,p_{v'})
&=\varrho(U_{v'}m,U_{v'}p_{v'})\\
&\le\kappa\varrho(m,p_{v'})\\
&\le\kappa(R+D_*)\\
&\le R.
\end{aligned}
$$

$\square$

If the fixed points are supplied and verified directly, completeness is unnecessary for this ball argument. Completeness is required for the stated Banach existence route.

Suppose the readers satisfy

$$
D_c(r_c(m),r_c(m'))\le L\varrho(m,m').
\tag{15.16}
$$

\]

For abstract laws \(r_c^*(v)=r_c(p_v)\), equation (15.7) holds with \(\eta=LR\).

Defining an abstract law from a fixed point does not by itself establish intended write fidelity. If \(\nu_{c,v}\) are the predeclared desired laws, additionally bound

\[
\beta=\sup_{v,c}D_c(r_c(p_v),\nu_{c,v}).
\]

Then the certificate's error is

\[
\eta=LR+\beta.
\tag{15.17}
\]

For a world whose state-changing actions are these writes, CR-15.2 applies. If other actions are registered, their matching-set invariance must also be proved. Having all outputs pass through the same reader does not prevent an intermediate action from amplifying a carrier difference.

**Initialization is a separate obligation.** The minimal radius \(R_*\) need not contain states after their first write from an arbitrary initialization.

For example, \(U(m)=m/2\) on \(\mathbb R\) has a single fixed point, so \(D_*=R_*=0\). Starting at \(m_0=1\), every finite iterate remains outside \(K=\{0\}\).

For a bounded initial set \(I\), a sufficient radius covering all post-first-write histories is

\[
R\ge
\max\left\{
R_*,
\ \kappa\sup_{m\in I,v}\varrho(m,p_v)
\right\}.
\tag{15.18}
\]

The second term places the first write inside its target ball; (15.15) handles every later write.

Alternatively, choose any reference initial value \(v_0\), and let

\[
e_0=\varrho(m_0,p_{v_0}).
\]

After \(t\) writes with last value \(v_t\),

\[
\varrho(m_t,p_{v_t})
\le
\kappa^t e_0+
R_*(1-\kappa^t).
\tag{15.19}
\]

This follows by iterating \(e_{t+1}\le\kappa(e_t+D_*)\). It gives a transient bound, not automatic finite-time entry into the minimal balls.

**Synchronized forgetting.** Two states subjected to the same sequence of \(k\) writes satisfy

\[

\varrho(U_wm,U_wm')\le\kappa^k\varrho(m,m').

\tag{15.20}

\]

This is a statement about a common suffix. A uniform bound over arbitrary earlier histories additionally requires a bound on their starting separation.

**Behavioral form.** On a complete invariant subset of \(Q\), one may take \(\varrho=\bar d\). Then immediate readers are automatically \(1\)-Lipschitz, and contraction and ball diameters are behavioral statements. Establishing that hypothesis, however, requires control of all registered futures; it is not supplied by a short list of continuation tests.

**Correction to the scalar GRU interval argument.** Let

\[

U_v(h)=\tfrac12h+\tfrac12\tanh(kh+\ell v)

\]

be the earlier exact construction, with

\[

A=\operatorname{atanh}(a),\quad

B=\operatorname{atanh}(3a),\quad

k=\frac{A-B}{2a},\quad

\ell=\frac{A+B}{2a},

\quad 0<a<1/3.

\]

It satisfies \(U_a(-a)=U_a(a)=a\). On \([-a,a]\), the argument of \(\tanh\) lies in \([A,B]\subset(0,\infty)\), and

\[

U_a''(h)=\tfrac12k^2\tanh''(kh+\ell a)<0.

\]

Strict concavity therefore gives

\[

U_a(h)>a\qquad(-a<h<a).

\tag{15.21}

\]

Thus \([-a,a]\) is not invariant. A small derivative bound on that interval cannot certify repeated operation there.

The two-point carrier \(\{-a,a\}\) remains invariant, and on that carrier each write has contraction factor zero.

**CR-15.4. Selective contraction: what fails and a sufficient replacement**

Strict contraction in an addressed direction and \(1\)-Lipschitz behavior elsewhere do not imply selective memory.

First,

\[

U_{1,v}(x,y)=(v,0)

\]

contracts the addressed coordinate completely and is nonexpansive in the other coordinate, while destroying every distinction carried by \(y\).

Second, even exact preservation of the unaddressed coordinate and consistent fixed-point intersections do not imply commutation.

On \(M=[0,1]^2\), for \(v,u\in\{0,1\}\) and \(0<\kappa\le1/2\), define

\[

U_{1,v}(x,y)=\bigl(v+\kappa y(x-v),y\bigr),

\qquad

U_{2,u}(x,y)=(x,u).

\tag{15.22}

\]

Both maps preserve the unaddressed coordinate. The addressed contraction factors are at most \(\kappa\) and zero. Their fixed sets are

\[

\operatorname{Fix}(U_{1,v})=\{v\}\times[0,1],

\qquad

\operatorname{Fix}(U_{2,u})=[0,1]\times\{u\},

\]

with the unique consistent intersection \((v,u)\).

Nevertheless, the first coordinates of the two write orders differ by

\[

\kappa(u-y)(x-v).

\tag{15.23}

\]

At \((x,y)=(1,0)\), \(v=0,u=1\), that difference is \(\kappa\).

This is also a behavioral counterexample. Register the two Bernoulli coordinate readers. The absolute derivative row sum of the first component of \(U_{1,v}\) is

\[

\kappa y+\kappa|x-v|\le2\kappa\le1.

\]

Both writes are therefore nonexpansive in the maximum metric. Immediate observations attain that metric, so

\[

d_\infty((x,y),(x',y'))

=\max\{|x-x'|,|y-y'|\}.

\]

The commutation defect in the displayed example is exactly \(\kappa\).

Consistent fixed points describe the result of settling; they do not specify the error after a finite write.

Conversely, compatible *raw-carrier* fixed sets are unnecessary for behavioral commutation. Attach an unread bit to an exact register store. Let writes to register 1 set it to zero and writes to register 2 set it to one. The corresponding raw fixed sets are disjoint, but their write maps commute exactly on the behavioral quotient.

Thus the proposed “if and only if” is invalid.

**Theorem: a sufficient selective-tube certificate.**

For each preserved context \(b\), suppose a carrier presentation

\[

M_b=\prod_{r\in R}M_{b,r}

\]

is supplied. Each factor has a metric \(\varrho_{b,r}\). A write preserves \(b\) and every unaddressed coordinate exactly:

\[

U_{r,v}(b,m)=

\bigl(b,m_{-r},G_{b,r,v}(m_r;m_{-r})\bigr).

\tag{15.24}

\]

Assume these are self-maps of the declared carrier.

For each addressed factor, supply anchors $p_{b,r,v}$ and uniform bounds

$$
\varrho_{b,r}(G_{b,r,v}(x;n),G_{b,r,v}(x';n))
\le\kappa_r\varrho_{b,r}(x,x'),
\quad \kappa_r<1,
\tag{15.25}
$$

$$
\varrho_{b,r}(G_{b,r,v}(p_{b,r,v};n),p_{b,r,v})
\le\xi_r
\tag{15.26}
$$

for every admissible unaddressed state $n$.

Let

$$
D_r=\sup_{b,u,v}\varrho_{b,r}(p_{b,r,u},p_{b,r,v})
$$

be finite, and choose finite radii satisfying

$$
R_r\ge\frac{\kappa_rD_r+\xi_r}{1-\kappa_r}.
\tag{15.27}
$$

Then

$$
K_{b,\sigma}
=
\prod_r
\{m_r:\varrho_{b,r}(m_r,p_{b,r,\sigma(r)})\le R_r\}
\tag{15.28}
$$

is invariant under abstract coordinate replacement.

*Proof.* If the previous addressed value is $u$, then

$$
\begin{aligned}
\varrho_{b,r}(G_{b,r,v}(m_r;m_{-r}),p_{b,r,v})
&\le
\kappa_r\varrho_{b,r}(m_r,p_{b,r,v})+\xi_r\\
&\le
\kappa_r(R_r+D_r)+\xi_r\\
&\le R_r.
\end{aligned}
$$

Every other coordinate remains in its previous ball by exact preservation. $\square$

Independent component updates \(G_{b,r,v}(m_r)\) are an immediate special case. On complete invariant factors, Banach supplies their anchors and \(\xi_r=0\).

For partially initialized stores, choose initial coordinates \(i_{b,r}\), set

\[
K_{b,r,\bot}=\{i_{b,r}\},
\]

and additionally require

\[
R_r\ge
\kappa_r\sup_{b,v}\varrho_{b,r}(i_{b,r},p_{b,r,v})+\xi_r.
\tag{15.29}
\]

The same proof covers a register's first write. Untouched coordinates remain in their singleton sets.

If readers are uniformly \(L\)-Lipschitz in the product maximum metric, and their calibration error at every declared center against the intended abstract laws is at most \(\beta\), then (15.30) holds. When untouched tags are included, this calibration includes mixed centers containing both write anchors and untouched initial coordinates. Explicitly,

\[
\eta=\beta+L\max_rR_r.
\tag{15.30}
\]

Subject to matching-set invariance for every additional registered action, CR-15.2 supplies:

- absorption and commutation defects at most \(2\eta\);
- history-to-normal-form discrepancy at most \(2\eta\);
- surviving abstract response margins at least \(\Delta-2\eta\).

This theorem supplies a sufficient metric certificate. It **assumes** a product presentation and preservation conditions; contraction does not derive them. Behavioral invariant relations remain the coordinate-independent conclusion.

At \(\kappa_r=\xi_r=\beta=0\), choose the admissible minimal radii \(R_r=0\). The written-coordinate sets are then singletons. Independently of that radius choice, equations (15.25)–(15.26) imply \(G_{b,r,v}(x;n)=p_{b,r,v}\) for every admissible \(x,n\), so the transition is exact replacement. With faithful native reads, its behavioral quotient falls under CR-15.1. Unobservable distinctions in \(b\) may be quotiented out.

**Corollary: global fading is incompatible with indefinite preservation.**

Suppose two states differ in a live register \(s\), and repeated writes to another register \(r\) preserve a native response separation \(\delta>0\). Those writes cannot have a uniform global behavioral contraction factor \(\kappa<1\), because that would imply

\[
0<\delta
\le d_\infty(U_{r,v}^nx,U_{r,v}^ny)
\le\kappa^n d_\infty(x,y)
\longrightarrow0.
\]

Indefinite preservation rules out uniform global behavioral fading under the corresponding writes. A selective-overwrite implementation must erase the addressed distinctions while allowing preserved distinctions to survive; addressed erasure need not arise from carrier contraction.

**CR-15.5. A shared sigmoid gate can realize selective overwrite**

**Theorem.** A gated neural recurrence with a constant, address-independent sigmoid gate can satisfy strict behavioral contraction in the addressed register's fiber and exact preservation across other registers.

*Construction.* Take

\[
M=[-a,a]^2,\qquad V_1=V_2=\{-a,a\},\qquad 0<a<1/3.
\]
Choose \(0\le\theta<1\). For a write to address \(r\), let \(q_i=\mathbf1\{i=r\}\). Use the shared gate
\[
g=\operatorname{sigmoid}(0)=\tfrac12
\]
and candidate
\[
C_i(m,r,v)
=
m_i+2(1-\theta)q_i(v-m_i).
\]
The gated recurrence is
\[
U_i=(1-g)m_i+gC_i
=
\begin{cases}
\theta m_i+(1-\theta)v,&i=r,\\
m_i,&i\ne r.
\end{cases}
\tag{15.31}
\]
Thus \(M\) is invariant.

This candidate is realizable by a finite ReLU network. For \(|t|\le2a\) and \(q\in\{0,1\}\), define
\[
H(q,t)
=
\operatorname{ReLU}(t+2aq)
-\operatorname{ReLU}(t-2aq)-2aq.
\]
If \(q=0\), it equals zero; if \(q=1\), it equals \(t\). Hence
\[
H(q,t)=qt,
\]
and the candidate uses \(H(q_i,v-m_i)\). All weights are finite, and the sole sigmoid gate remains constant.

Register native response channels
\[
r_i(m)=\operatorname{Bernoulli}
\left(\frac{m_i+a}{2a}\right),
\]
with total variation distance. Every write is nonexpansive in the maximum metric, and immediate responses attain that metric, so
\[
d_\infty(m,m')

=

\frac{\|m-m'\|_\infty}{2a}.

\tag{15.32}

\]

For pairs differing only in the addressed register,

\[

d_\infty(U_{r,v}m,U_{r,v}m')

=

\theta\,d_\infty(m,m').

\tag{15.33}

\]

For pairs differing only in the other register, the distance is preserved exactly.

When \(\theta=0\), writes perform exact coordinate replacement. They satisfy A1–A3 and preserve the unrelated register exactly. \(\square\)

The choice \(g=1/2\) is not essential. For any fixed \(g\in(0,1)\), the candidate

\[

C_i=m_i+\frac{1-\theta}{g}q_i(v-m_i)

\]

produces the same transition with finite weights. Thus address selection need not occur in the sigmoid gate. This is a gated neural cell with a ReLU candidate, not an exact-representability result for a stock affine–tanh GRUCell or evidence that training discovers the mechanism.

Address dependence remains present in the candidate. A useful two-register writer must select an address somewhere in its full transition map. The theorem shows that this selection need not occur in the sigmoid gate.

For \(0<\theta<1\), the construction also demonstrates that strict behavioral contraction is not identical to exact overwrite absorption. Repeated same-value writes continue moving a nonfixed addressed state toward its target.

This is an existence construction, not evidence that training discovers the mechanism.

**CR-15.6. What is used, what is not claimed, and the \(\mathbb R^n\)-trap check**

The invariant-relation argument uses established approximate simulation and bisimulation reasoning. In a deterministic system with matching action labels, transition closure and bounded observation error give uniform trajectory bounds. These are existing foundations, not a novelty claim. [Girard and Pappas, *Approximate Bisimulations for Nonlinear Dynamical Systems*](https://skoge.folk.ntnu.no/prost/proceedings/cdc-ecc05/pdffiles/papers/0712.pdf)

The contraction arguments use Banach’s theorem and familiar forgetting estimates associated with echo-state and fading-memory theory. A uniform one-step contraction factor below one is a sufficient condition; it must not be equated with every form of echo-state behavior. Persistent unaddressed registers also prevent global forgetting under arbitrary input sequences. [Jaeger, *The “Echo State” Approach to Analysing and Training Recurrent Neural Networks*, including the erratum](https://www.ai.rug.nl/minds/uploads/EchoStatesTechRep.pdf)

Hahn’s Lemma 5 bounds single-token influence by \(O(1/n)\) for the specified fixed-depth soft-attention architecture. It supplies relevant prior art for bounded-influence arguments. It does not establish that positive attention to obsolete tokens creates a nonzero behavioral overwrite defect. [Hahn, *Theoretical Limitations of Self-Attention in Neural Sequence Models*](https://aclanthology.org/2020.tacl-1.11.pdf)

**Restricted paired-pool fidelity lemma.** Let

\[

y=\sum_{i=0}^{m}\alpha_i a_i,\qquad

y'=\sum_{i=0}^{m}\alpha_i a_i'

\]

use the same softmax weights

\[

\alpha_i=\frac{e^{\ell_i}}{\sum_j e^{\ell_j}}.

\]

Position \(0\) is live; all \(m\) other values are unchanged. Suppose \(\ell_0-\ell_j\le B\) for \(j\ge1\), and \(\|a_0-a_0'\|\le D_{\mathrm{val}}\). Let the common downstream response map \(\Phi\) be \(L\)-Lipschitz, with all other arguments fixed and no additional changing route.

Then

\[

\alpha_0\le\frac{e^B}{m+e^B},

\qquad

D_c(\Phi(y),\Phi(y'))

\le LD_{\mathrm{val}}\frac{e^B}{m+e^B}.

\]

If intended response laws have separation at least \(\Delta\), and each realized response is within \(\eta\) of its intended law, the triangle inequality gives

\[

\Delta-2\eta

\le LD_{\mathrm{val}}\frac{e^B}{m+e^B}.

\tag{15.34}

\]

A dilution conclusion as \(m\) grows requires \(B,D_{\mathrm{val}},L\) bounded independently of \(m\) and \(\Delta>2\eta\). Changing weights, distractor values, or another information route introduces terms absent from this bound. This is a fidelity obstruction for the declared pool, not an absorption theorem or an architecture-wide result.

**State tracking and architectural scope.** Fixed-depth log-precision transformers admit simulation by uniform constant-depth threshold circuits under the stated computational model. This is a resource-specific expressivity bound, not a theorem that transformers cannot implement any register update. [Merrill and Sabharwal, *The Parallelism Tradeoff*, Theorem 2 and Corollary 2.1](https://aclanthology.org/2023.tacl-1.31/).

Conversely, transformers have constructive shortcuts for finite-state computation: logarithmic-depth simulations exist generally, and constant-depth constructions cover substantial subclasses. Memory/reset units are explicit ingredients. The constructions' resources, including weights or width, can depend on sequence length; they do not contradict fixed-resource bounded-influence results. [Liu et al., *Transformers Learn Shortcuts to Automata*, Theorems 1–2 and Appendix C.3](https://arxiv.org/abs/2210.10749).

Input-dependent propagation, forgetting, and boundary reset are already central to selective state-space models. Their existence does not establish CR-15's exact keyed-write laws or indefinite preservation at finite parameters. [Gu and Dao, *Mamba*, §3.5](https://arxiv.org/html/2312.00752v2).

Nor does a recurrent state representation alone establish general state-tracking ability: the analyzed state-space-model families also have expressivity restrictions under specified precision and architectural assumptions. [Merrill, Petty, and Sabharwal, *The Illusion of State in State-Space Models*](https://arxiv.org/html/2404.08819v2).

Nor are contraction and dilution an exhaustive architectural dichotomy. An append-only state space is still a set on which a metric can be defined; variable length alone does not preclude metric arguments. Conversely, behaviorally irrelevant carrier components may expand or rotate without damaging overwrite.

**Explicit trap check:** Are we describing the world's erased and preserved response distinctions, or merely finding a favorable norm on its arrays?

The exact kernels, partial-write action, invariant behavioral relations, and \(d_\infty\) bounds survive arbitrary bijective recoding with the registered actions and responses transported accordingly. Those are the behavioral objects.

Carrier norms, product charts, Jacobian bounds and Euclidean balls are **surgeon certificates**. They can establish behavioral consequences, but their numerical convenience is not itself a native law. A chosen norm's contraction does not establish learned register semantics, and failure of that norm's certificate does not refute behavioral overwrite.

**CR-15.7. Falsifiers and the single cheapest certificate check**

The claims have separate failure conditions:

- **Mathematical theorem:** a system satisfying every stated premise but violating its conclusion would refute the theorem. Violating a premise only prevents its application.
- **Concrete overwrite claim:** a legal continuation with response discrepancy above the claimed tolerance refutes the full \(d_\infty\) bound. A finite-horizon failure suffices; finite-horizon agreement does not certify the infinite horizon.
- **Useful selective memory:** loss of the declared live-value or unrelated-register distinction refutes that preservation claim, even if erasure succeeds.
- **Contraction certificate:** an unverified domain, missing initialization coverage, missing transition closure, or inadequate reader margin prevents certification. A system realizing overwrite without contraction would demonstrate another supplier, not refute a sufficient contraction theorem.
- **Architectural advantage:** equality between matched sealed and unsealed systems defeats the claimed advantage on that endpoint. It does not refute selective behavioral reset.

A maximum over sampled Jacobian norms is not a uniform contraction certificate. A derivative-based proof requires a bound over the whole relevant domain and justified passage from derivatives to finite distances—for example, integration along segments in a verified convex domain. D7's local derivative object does not replace those obligations or control unexamined futures.

**Single cheapest check, if later implemented:** verify the shared-gate construction at \(\theta=0\) on the closed four-state carrier

\[
M_0=\{-a,a\}^2.
\]

There are four states and four write actions: **16 transitions**.

For every transition, check together:

\[
U_{r,v}(m)\in M_0,\qquad
U_{r,v}(m)_r=v,\qquad
U_{r,v}(m)_s=m_s\quad(s\ne r).
\tag{15.35}
\]

The expected result is exact coordinate replacement. Closure plus this table proves the write laws for every history length by induction; the registered readers give exact live-value separation. No long-history sampling, fitting, or training is needed.

Checking preservation and fidelity together excludes the cheapest misleading alternatives: global reset can erase history while destroying the other register; identity can preserve the other register while failing to write.

Any incorrect table entry falsifies the implementation of this construction. A passing check verifies this finite constructed realization only. It supplies no evidence of learned discovery or generalization. The principal implementation confound is an address-based overwrite performed outside the gated cell being tested.

The mathematical substitution above already establishes the table analytically. No numerical run is required for this section.

**CR-15.8. Exact behavioral state budgets bound accumulated write-law error**

Status: THEOREMS AND CONSTRUCTED SHARPNESS EXAMPLES (analytic round 3,

2026-09-05). Audit #40 adopts the mathematical core, with explicit parameter

guards and prior-art attribution applied below. This resolves audit #39's

state-budget question under the stated full-behavioral premises. No

learned-interface application is established. No compute was used.

**Lemma (joint-state loop cutting and linear rewrite count).** With \(S_0,N,\mathcal P\) as defined below, the deterministic joint transition sends \((q,\alpha)\) to \((F_{r,v}q,\alpha[r\leftarrow v])\). Equal joint prefix states permit deleting the intervening actions while preserving both the final concrete endpoint and the final normal form. Repeated deletion leaves a simple joint-state path of length at most \(N|\mathcal P|-1\).

An unqualified 'each write is crossed at most once per register' claim is false. In the execution-order word

\[
r\,r\,s\,r,

\]

eliminating the second \(r\) before the first makes the surviving \(s\) cross two dead \(r\)-writes. The claim needs a specified elimination order; the final canonical sorting also needs accounting.

A clean repair processes the word **right to left**, maintaining a canonically ordered suffix containing at most one write per register. An older write either:

- crosses other-register writes until it meets its later same-register write, then is absorbed; or
- is inserted into its canonical position if its register is absent.

For a length-\(n\) word touching \(k\) registers, there are \(n-k\) absorptions, at most \((k-1)(n-k)\) swaps associated with them, and at most \(\binom{k}{2}\) insertion swaps. Thus

\[
\rho(w)\le k(n-k)+\binom{k}{2}\le kn.
\]

This proves a linear rewrite bound, including sorting; combined with joint-state loop cutting it gives a history-uniform bound with a factor |R|·N·|□|. The theorem below makes that count unnecessary for lifetime control.

**Definitions and scope.** Work in CR-15.0's registered deterministic world, with behavioral quotient \(Q\), metric \(\bar d\le1\), and nonexpansive legal writes \(F_{r,v}\). Fix an initial place \(q_0\).

The **exact finite-state premise** is an independently established bound

\[
S_0:=\{F_wq_0:w\text{ is a finite write history}\},
\qquad |S_0|\le N<\infty.
\]

This bounds the entire write orbit, not sampled states, a finite-horizon partition, or a tolerance cover. It must not be inferred by applying CR-11's exact-law orbit bound to approximate laws.

Assume uniformly for every \(q\in S_0\):

\[
\bar d(F_{r,v'}F_{r,v}q,F_{r,v'}q)\le\varepsilon,
\tag{A1(\(_\varepsilon\))}
\]

\[
\bar d(F_{r,v}F_{s,u}q,F_{s,u}F_{r,v}q)\le\varepsilon
\qquad(r\ne s).
\tag{A2(\(_\varepsilon\))}
\]

Let

\[
\mathcal P=\prod_{r\in R}(V_r\sqcup\{\bot\})
\]

be the partial-store monoid of CR-15.1. The map \(\operatorname{nf}\) records each register's last-written value or untouched status. It is defined syntactically even when the concrete laws are approximate.

Choose a fixed canonical execution order for registers. Let \(P_\alpha\) denote execution of that canonical word for \(\alpha\). **Under approximate laws, \(P_\alpha\) is not assumed to constitute an exact monoid action.**

For each \(\alpha\), define the behavioral realization set

\[
K_\alpha
=

\{F_wq_0:\operatorname{nf}(w)=\alpha\}.

\]

These nonempty sets cover \(S_0\), may overlap, and satisfy write-transition closure:

\[

F_{r,v}(K_\alpha)\subseteq K_{\alpha[r\leftarrow v]}.

\]

**Theorem.** Under the exact finite-state premise and A1\(_\varepsilon\)–A2\(_\varepsilon\),

\[

\operatorname{diam}_{\bar d}K_\alpha

\le

\min\{1,(|K_\alpha|-1)\varepsilon\}

\le

B_N,

\qquad

B_N:=\min\{1,(N-1)\varepsilon\}.

\]

Consequently,

\[

\bar d(F_wq_0,P_{\operatorname{nf}(w)}q_0)\le B_N

\]

for every history length. Any two histories with the same normal form satisfy the same bound \(B_N\), without an additional factor of two.

**Proof.**

First consider one absorption or commutation rewrite inside a word. Its unchanged prefix reaches a state in \(S_0\), where the applicable approximate law bounds the discrepancy by \(\varepsilon\). Applying the unchanged suffix cannot increase that discrepancy, since every write is nonexpansive. Therefore one rewrite changes the full word’s endpoint by at most \(\varepsilon\).

The right-to-left normalization procedure above transforms every word into its canonical normal form through finitely many such rewrites. Every intermediate word has the same normal form and reaches a state in \(K_\alpha\).

For histories \(u,v\) with normal form \(\alpha\), concatenate the normalization of \(u\) with the reversed normalization of \(v\). Their endpoints form a finite chain

\[

x_0=F_uq_0,\ x_1,\ldots,x_L=F_vq_0,

\qquad

\bar d(x_i,x_{i+1})\le\varepsilon,

\]

entirely inside \(K_\alpha\).

Whenever a vertex repeats, delete the intervening closed portion of this endpoint walk. The resulting walk has the same endpoints and retains the edge bounds. It contains at most \(|K_\alpha|\) distinct vertices, hence at most \(|K_\alpha|-1\) edges. The triangle inequality gives

\[

\bar d(F_uq_0,F_vq_0)

\le (|K_\alpha|-1)\varepsilon.

\]

The ambient bound \(\bar d\le1\) supplies the cap. Taking \(v\) to be the canonical word proves the history-to-normal-form statement. \(\square\)

The shortened endpoint walk need not itself encode a shortened execution history or a syntactic derivation. Only its metric edge bounds are used. This is why no partial-store factor is needed.

**Faithful native reads and preservation.** The metric theorem does not require fidelity; fidelity makes its conclusion a useful store statement.

Suppose a registered native response $r_r$ has intended laws $\nu_{r,v}$, with uniform own-write calibration

$$
D_r(r_r(F_{r,v}q),\nu_{r,v})\le\beta
\qquad(q\in S_0).
$$

For deterministic faithful reads as in A3, take $\nu_{r,v}=\delta_v$ and $\beta=0$.

If $\alpha(r)=v$, choose a representative word for $\alpha$ that executes its $r$-write last. Its endpoint lies in $K_\alpha$ and satisfies the calibration condition. Hence every $q\in K_\alpha$ satisfies

$$
D_r(r_r(q),\nu_{r,v})\le B_N+\beta.
$$

If two intended live-value laws have native separation at least $\Delta$, their realizations remain separated by at least

$$
\Delta-2(B_N+\beta).
$$

This also protects their distinction after subsequent writes to other registers, because those writes leave their last-written $r$-values unchanged syntactically.

A positive preservation claim therefore requires

$$
\Delta>2(B_N+\beta).
$$

Untouched registers and arbitrary preserved context require their own declared reference distinctions; they do not inherit semantics merely from the symbol $\bot$.

**Parameter guards.** Throughout, $N$ is a positive integer and $\varepsilon,\tau$ are nonnegative. The binary phase construction assumes even $m\ge2$ and $\varepsilon>0$. The nontrivial singleton-register envelope construction assumes $N\ge2$ and $\varepsilon>0$. For $N=1$ or $\varepsilon=0$, the upper envelope is zero and is attained by a one-place behavioral system; the zero-spacing scalar presentation must be quotiented before counting exact behavioral places. Note that for deterministic native reads with TV distance and $\beta=0$), $\varepsilon<1$ already forces every rewrite edge to preserve that read exactly, so the binary phase example below accumulates nuisance-response error while its live bit remains exact; it does not demonstrate corruption of the stored value (audit #40).

**Lower bound with nonvacuous faithful reads.** The following phase presentation is a constructed surgeon certificate for a counterexample, not a claim about discovered latent coordinates.

Let $m$ be even and take

$$
Q=\{0,1\}\times\mathbb Z_m,\qquad
F_v(s,j)=(v,j+1).
$$

Register an exact binary-value response and the nuisance response

$$
r(s,j)=\operatorname{Bernoulli}
\left(\frac{1+a\cos(2\pi j/m)}2\right),
\qquad 0<a\le1.
$$

\]

Use total variation distance.

All \(2m\) exact behavioral places are reachable. Every common continuation preserves phase differences. Consequently,

\[

\bar d(F_{v'}F_vq,F_{v'}q)

\le a\sin(\pi/m).

\]

There is one register, so commutation is vacuous. Native value fidelity has margin \(1\).

Starting at phase \(-1\), compare \(F_v\) with \(F_v^{m/2+1}\). Their final phases are \(0\) and \(m/2\); their nuisance response discrepancy is \(a\), despite identical normal forms.

Choose

\[

a=\min\left\{1,\frac{\varepsilon}{\sin(\pi/m)}\right\}.

\]

The local laws are \(\varepsilon\)-accurate, while lifetime error is

\[

\Omega\!\left(\min\{1,N\varepsilon\}\right),

\qquad N=2m.

\]

Thus the linear dependence on the **exact behavioral state budget** is necessary even with \(|R|=1\), \(|\mathcal P|=3\), and faithful native margin \(1\).

**Sharpness status.** The universal upper bound has no register-count or partial-store-count multiplier. Its order

\[

\Theta\!\left(\min\{1,N\varepsilon\}\right)

\]

is established by the binary example above.

The exact envelope \(\min\{1,(N-1)\varepsilon\}\) is attained over the stated class permitting singleton value sets. To see this, use a constructed scalar surgeon certificate:

\[

Q=\{0,\ldots,N-1\},\quad

A(j)=\min(j+1,N-1),\quad

B(j)=\max(j-1,0).

\]

Let \(A,B\) be writes to two singleton-valued registers. Register the nuisance response \(\operatorname{Bernoulli}(jh)\), where

\[

h=\min\{\varepsilon,1/(N-1)\}.

\]

Then

\[

\bar d(i,j)=h|i-j|,

\]

because immediate responses attain this distance and both maps are nonexpansive. Absorption and commutation defects are at most \(h\).

From \(0\), the canonical execution \(A,B\) returns to \(0\), whereas the same-normal-form history \(B,A^{N-1}\) reaches \(N-1\). Its discrepancy is exactly

\[

(N-1)h=\min\{1,(N-1)\varepsilon\}.

\]

Singleton-register fidelity is vacuous. This exact-constant example must therefore accompany, rather than replace, the binary faithful-read example. Optimal constants when every register must have multiple separated values are not established here.

**Why joint-state counting still needs normal-form information.** The error theorem does not imply that the joint system has only \(N\) states.

For \(k\) exact binary registers initialized to zero, there are

\[

N=2^k

\]

behavioral stores but

\[

3^k

\]

reachable joint states: each partial-store tag is reachable, and its concrete store fills untouched entries with zero. A concrete zero does not identify whether that register was untouched or explicitly written.

More starkly, \(k\) singleton-valued identity registers give \(N=1\) and \(2^k\) reachable partial-store tags. A history touching all registers needs at least \(k\) actions to preserve its normal form, although its concrete endpoint never changes.

Thus cutting execution loops using \(q\) alone need not preserve \(\operatorname{nf}\). Joint-state cutting must track the normal form or enforce an equivalent preservation condition. **The endpoint-chain proof avoids this obligation; it does not invalidate it.**

**Tolerance-world replacement.** Without an exact finite quotient, the bound \((N-1)\varepsilon\) does not follow from \(N\) resolution cells.

A different theorem survives. Define the packing number using the **full behavioral metric**:

\[

\operatorname{pack}_\tau(S_0)

=

\sup\{|E|:E\subseteq S_0,\

\bar d(x,y)>\tau\text{ for distinct }x,y\in E\}.

\]

If

\[

\operatorname{pack}_\tau(S_0)\le N,

\]

then

\[

\boxed{

\operatorname{diam}K_\alpha

\le

\min\{1,N\tau+(N-1)\varepsilon\}.

}

\]

Here \(N\) is a packing bound, **not an exact-state bound**.

*Proof.* Take the normalization endpoint chain \(x_0,\ldots,x_L\), and put

\[

t_i=\bar d(x_0,x_i).

\]

Consecutive radii differ by at most \(\varepsilon\).

Starting with radius zero, repeatedly select the first later chain point whose radius exceeds the previously selected radius by \(\tau\). Each new selected radius is at most \(\tau+\varepsilon\) above its predecessor.

If the terminal radius exceeded \(N\tau+(N-1)\varepsilon\), this procedure would select \(N+1\) points. Their radii, and hence their pairwise distances by the reverse triangle inequality, would differ by more than \(\tau\). This contradicts the packing bound. \(\square\)

A cover by \(N\) sets of diameter at most \(\tau\) suffices. A cover by \(N\) balls of radius \(\tau\) instead supplies

\[

\min\{1,2N\tau+(N-1)\varepsilon\}.

\]

Finite immediate-read bins do not establish either full-behavioral premise.

The resolution floor is unavoidable in general. As a constructed scalar surgeon example, take \([0,D]\), with \(D=N\tau\le1\), Bernoulli response \(\operatorname{Bernoulli}(x)\), and writes

\[

A(x)=\min(x+a,D),\qquad B(x)=\max(x-b,0),

\]

Assume \(N\ge1,\tau>0,D=N\tau\le1\), and \(\varepsilon>0\). Choose \(0<a<b\le\varepsilon\) with \(a/b\) irrational and \(a+b<D\). These are singleton-register writes.

Their absorption defects are at most \(a,b\), and their commutation defect is at most \(\min(a,b)\). The behavioral metric is \(|x-y|\). The reachable orbit is infinite: choosing \(A\) when \(x<b\) and \(B\) otherwise implements an irrational rotation on \([0,a+b)\). Nevertheless, its packing number at strict separation \(>\tau\) is at most \(N\).

From zero, the execution-order word \(A,B\) returns to zero because \(a<b\), while \(B,A^n\) reaches \(D\) whenever \(n\ge\lceil D/a\rceil\). Both words have the same normal form, so their discrepancy is exactly \(D=N\tau\). Such steps exist for every \(\varepsilon>0\). Thus fixed-resolution packing permits a nonzero lifetime error floor as uniform local defects tend to zero; at \(\varepsilon=0\), equal-normal-form histories coincide.

**Prior art (audit #40).** The proof combines established quantitative equational reasoning with an elementary finite-chain diameter bound: nonexpansive contexts preserve rewrite error, triangle inequalities compose errors, and a loop-erased walk on \(M\) vertices has at most \(M-1\) edges. Quantitative algebra and metric rewriting supply direct antecedents [Mardare, Panangaden, Plotkin, *Quantitative Algebraic Reasoning* (2016), Defs. 2.1, 3.1](https://www.cs.mcgill.ca/~prakash/Pubs/lics2016.pdf), [Gavazzo, Di Florio, *Quantitative and Metric Rewriting*](https://arxiv.org/abs/2206.13610); Moore-style behavioral equivalence [Moore (1956)](https://www.cs.cmu.edu/~cdm/resources/Moore1956-gedanken-experiments.pdf) and approximate simulation [Girard, Pappas (2007), Prop. 2, Lemma 5](https://www.georgejpappas.org/wp-content/uploads/2024/04/GP07-TAC.pdf) supply the transition-system background; a transition-closed approximate bisimulation maintains its tolerance along trajectories and should not be described as accumulating error at every step. These citations identify foundations, not a source verified to state this particular sharp selective-write corollary. No priority claim is made.

**Relation to CR-15.2 and CR-15.3; additional suppliers.** CR-15.2 requires transition closure and uniformly accurate response laws. The sets \(K_\alpha\) already have write-transition closure. The exact finite-state theorem derives their small behavioral diameter from approximate local laws plus a state budget. Contraction in CR-15.3 provides a different sufficient certificate for small realization sets.

They are not exhaustive alternatives:

- A transition-closed relation with uniformly bounded response error can be established directly, without finite exact state or contraction.
- Full-behavioral packing gives the resolution-dependent bound above.
- If the **registered behavioral metric \(\bar d\) itself is ultrametric**, every finite \(\varepsilon\)-chain has diameter at most \(\varepsilon\), by repeated strong triangle inequalities. The rewrite proof then gives lifetime error at most \(\varepsilon\), without finite state or strict contraction.

CR-5's separate ultrametric \(2^{-d_{\rm Sep}}\) does **not** establish that the registered \(\bar d\) is ultrametric.

The common requirement is control of the diameter of endpoint sets connected by small rewrite defects. Finite counting, suitable metric structure, and invariant relations supply that control in different ways.

If additional actions are registered, the theorem's \(\bar d\)-bound already controls all common registered continuations. It does not automatically furnish abstract partial-store transitions for those additional actions; applying CR-15.2 to them still requires matching abstract dynamics and closure.

**Falsifiers and application failures.**

- A system satisfying the exact finite-state premise and every uniform law but exceeding the theorem's bound would refute the theorem.
- More than \(N\) reachable exact behavioral places, an excessive local defect, or missing action/domain coverage prevents that finite-state application.
- A registered continuation exceeding a claimed behavioral tolerance refutes that concrete claim. Finite continuation agreement does not establish the infinite-horizon premises.
- A bound at or above the available native margin does not certify useful selective memory.
- None of these results establishes learned realization, transfer, causal substitution in a learned model, or architectural advantage.

The theorem uses registered actions, response distinctions, and exact behavioral counting. It assumes no product coordinates or invariant tubes. Scalar carriers, phase parameterizations, norms, and contraction calculations used to construct or verify examples remain **surgeon certificates**.

**CR-15.9. Register-free form: finite behavioral orbit bounds accumulated error of any approximate equational laws**

Status: THEOREM (re-contextualization round 1, 2026-09-05). Strict

generalization of CR-15.8: no registers, addresses, stores, or normal forms

are assumed; only actions, responses, a finite reachable orbit, and a finite

family of equational laws with explicit error. Adopted pending its own fresh

audit. Uses established quantitative equational reasoning (Mardare,

Panangaden, Plotkin 2016); no novelty claim.

Let \(A\) be an action alphabet acting deterministically on a behavioral metric space \((Q,\bar d)\), with \(\bar d\le1\). Use the project's rightmost-first composition convention. Fix \(q_0\), and assume its entire action orbit

\[
S_0=\{F_wq_0:w\in A^*\}
\]

contains at most \(N\) exact behavioral places.

Let \(E=\{(\ell_i,r_i)\}\) be word equations satisfying

\[
\bar d(F_{\ell_i}q,F_{r_i}q)\le\varepsilon
\qquad\text{for every }q\in S_0.
\]

Assume every action is nonexpansive. If equations are schemas, this bound must cover every substitution instance used.

Define \(\equiv_E\) as the **least two-sided monoid congruence generated by \(E\)**. Thus \(u\equiv_Ev\) means that a finite sequence of contextual replacements

\[
p\ell_i s\longleftrightarrow pr_i s
\]

connects them.

For each class \(\alpha\in A^*/{\equiv_E}\), define

\[
K_\alpha=\{F_wq_0:[w]_E=\alpha\}.
\]

Then

\[

\boxed{

\operatorname{diam}_{\bar d}K_\alpha

\le \min\{1,(|K_\alpha|-1)\varepsilon\}

\le \min\{1,(N-1)\varepsilon\}.

}

\]

**Proof.** A replacement \(p\ell_i s\leftrightarrow pr_i s\) starts its changed portion at \(F_sq_0\in S_0\). The law bounds the discrepancy there by \(\varepsilon\); applying \(F_p\) cannot increase it. A finite derivation therefore produces an endpoint walk inside \(K_\alpha\), every edge having length at most \(\varepsilon\). Delete portions between repeated endpoints. The remaining walk has at most \(|K_\alpha|-1\) edges. The triangle inequality gives the result, capped by the ambient diameter. The shortened walk need not remain a syntactic derivation. \(\square\)

This answers the specific attacks:

- **What replaces `nf` and the partial-store monoid?** The quotient map \(w\mapsto[w]_E\) and the presented monoid \(A^*/{\equiv_E}\). Neither a computable normal form nor a finite presentation quotient is required.
- **Is the proof register-free?** Yes. Registers supplied a particular equational presentation in CR-15.8; endpoint loop deletion uses only a bounded set of behavioral endpoints.
- **Does nonexpansiveness suffice?** It suffices to propagate each local law error through an unchanged continuation. Uniform law bounds, coverage of every intermediate state, and the finite endpoint bound remain separate hypotheses. In the full behavioral metric, nonexpansiveness is automatic.
- **Is the constant still \(N-1\)?** Yes, with no factor two. The stronger class-specific constant is \(|K_\alpha|-1\).
- **What does “exact theory” exclude?** Equality merely holding in a selected ideal model. For example, an identity action and a bit-flip action coincide in a one-state abstraction but differ maximally in a two-state concrete world. Their equality cannot be imported without a derivation from the controlled equations.
- **What about partial or typed actions?** Every replacement must preserve typing and legality, with the error bound valid at its actual prefix state. The unrestricted monoid statement does not automatically cover those cases.

The argument extends the existing [CR-15.8 proof](C:/Users/devan/OneDrive/Desktop/Projects/Latent-Space-Reasoning/theory/CONTINUATION_REFINEMENT.md:1248). Its ingredients belong to established quantitative equational reasoning; the generalization should carry no unsupported novelty claim. [Mardare, Panangaden and Plotkin](https://www.cs.mcgill.ca/~prakash/Pubs/lics2016.pdf).

**Finite orbit is sufficient, not necessary.** Take states \((b,x)\in\{0,1\}\times[0,1]\), writes \(F_v(b,x)=(v,x/2)\), an exact bit reader and a nuisance reader \(\mathrm{Bernoulli}(\delta x)\), \(0<\delta\le1\). From \((0,1)\) the exact behavioral orbit is infinite, yet every absorption defect is at most \(\delta/4\), any two nonempty histories with the same final bit differ by at most \(\delta/2\) under every common continuation, and bit fidelity is exact. This world is certified by contraction (CR-15.3), not by counting. The correct summary: local law accuracy alone gives no nontrivial universal lifetime bound over unrestricted worlds; finite orbit (CR-15.8/15.9), contraction (CR-15.3), and transition-closed invariant relations (CR-15.2) are alternative sufficient premises. "Local" means a short equation, not a short observation horizon: each law's \(\varepsilon\) already bounds every registered future, which remains the difficult application premise.

**CR-15.10. Interface-relative interchangeability: erasure is relative to a question family**

Status: DEFINITIONS AND PROPAGATION INEQUALITY (direction dialogue rounds

1-2, 2026-09-05). Organizing quantity: the modulus \(\omega_a(t)\) below.

Adopted pending its own fresh audit. Established behavioral mathematics

(Angluin, Myhill-Nerode, PSRs, OOMs, approximate bisimulation); no novelty

claim. Value must come from effective predictions about a real model, which

remain unestablished.

Setting. For a family \(W\subseteq A^*\times C\) of questions (continuation,

channel) define \(d_W(x,y)=\sup_{(w,c)\in W}D_c(r_c(T_wx),r_c(T_wy))\).

"The distinction between \(x\) and \(y\) is erased for \(W\)" means

\(d_W(x,y)\le\tau\). \(d_\infty\) is \(W=\) everything; CR-2's \(\equiv_h\)

is \(W=\) words of length \(\le h\); CR-9's \(Q_0\) pairs were erased for

\(W_0=\{(\epsilon,\mathrm{read})\}\). For \(aW=\{(wa,c):(w,c)\in W\}\)

(\(a\) executes first), the exact identity \(d_W(T_{ax},T_{ay})=d_{aW}(x,y)\)

holds with no hypothesis (CR-4's derivative restated for approximate

distinctions): an erased distinction stays erased under \(a\) for the

questions \(W\) exactly when it was already erased for the questions \(aW\).

**CR-15.10.1 Propagation inequality and its failure modes**

The identity is exact under [D1's composition convention](<C:/Users/devan/OneDrive/Desktop/Projects/Latent-Space-Reasoning/theory/AXIOMS.md:132>):

\[
T_{wa}=T_w\circ T_a.
\]

Consequently, defining \(aW=\{(wa,c):(w,c)\in W\}\),

\[
\boxed{d_W(T_{ax},T_{ay})=d_{aW}(x,y).}
\]

"Left-extension" is potentially confusing terminology: the notation \(aW\) appends \(a\) on the **right of the written word**, so that it executes first.

Here is replacement theorem text.

> *Let the registered actions be deterministic, and let the response discrepancies be true metrics bounded by one. Equip response profiles with the corresponding supremum metric. Write*
>
> *\[*
>
> *P(x)=(r_c(T_{wx}))_{(w,c)\in W},\qquad P_a(x)=P(T_{ax}).*
>
> *\]*
>

>
> *+2\sum_{i=1}^k\delta_{a_i}*
>
> *\prod_{j=i+1}^kL_{a_j}*
>
> *\right\}.}*
>
> *\]*

*Empty products equal one.*

The proof is exactly the triangle inequality followed by induction. The ordering of the amplification factors is as displayed. No extension of \(\Phi_a\) to unrealized profiles is necessary, because the induction compares actual trajectories.

The interpretation needs these corrections:

- **Exact closure preserves exact equality.** At \(\delta=0\), successor profiles are determined by current profiles precisely when

\[
P(x)=P(y)\Longrightarrow P(T_ax)=P(T_ay).
\]

No Lipschitz assumption is needed.

- **Exact closure need not preserve positive tolerances.** Take \(Z=[0,1]\), \(r(x)=\operatorname{Bernoulli}(x)\), \(W=\{(\epsilon,r)\}\), and \(T(x)=\min(1,2x)\). The profile determines the state exactly, so closure is exact, but small discrepancies can double.
- **A sufficient fixed-tolerance condition is**

\[
L_a\tau+2\delta_a\le\tau
\quad\text{for every }a.
\]

Thus \(L_a\le1,\delta_a=0\) suffices, but is not necessary. With uniform \(L<1\), nonzero defects are compatible with an invariant tolerance whenever \(2\delta\le(1-L)\tau\).

- With \(L\le1,\delta>0\), the bound \(\tau+2k\delta\) grows with the horizon. It does not establish safe forgetting at the original tolerance indefinitely.
- Closure established only on roots cannot be iterated through unverified successor states. Partial actions also require common legality or observable failure totalization.

The countdown example has a **factor-of-two error**. If two identical input profiles have successor laws separated by one, condition (C) requires \(\delta\ge\frac12\). For Bernoulli endpoint laws, their midpoint attains \(\delta=\frac12\), if arbitrary probability profiles are permitted as predictions. The successor **diameter** is one; the optimal prediction **radius** need not be one.

I would retain (C) as a certificate and use this definition as the organizing quantity:

\[
\boxed{
\omega_a(t)=
\sup_{\substack{x,y\in S\\d_W(x,y)\le t}}
d_W(T_ax,T_ay).
}
\]

It gives the precise statements directly:

- Exact profile closure: \(\omega_a(0)=0\).
- Preservation of tolerance \(\tau\): \(\omega_a(\tau)\le\tau\).
- the profile-map certificate: \(\omega_a(t)\le L_at+2\delta_a\).
- Propagation along a word: compose the \(\omega_{a_i}\), subject to domain coverage.

At \(t=0\), this is the maximum successor diameter of exact \(W\)-classes. Class diameter alone cannot control nearby **different** profiles, so it is insufficient for approximate propagation. Moreover, \(d_W\le\tau\) is generally not an equivalence relation; it must not silently become a quotient.

This definition is an exact reformulation, not yet a predictive discovery. Its value must come from obtaining useful bounds without enumerating every pair and future.

**CR-15.10.2 Correspondence with CR-15.2**

The proposed identification is **not generally exact**, and the dividing line is not simply “\(\delta=0,L\le1\).”

Assume \(S\) is action-invariant and \(W\) contains every immediate registered channel. Exact profile closure supplies

\[
\Lambda=P(S),\qquad
K_p=\{x\in S:P(x)=p\},
\]

\[
f_a(p)=P(T_ax),\qquad r_c^*(p)=p(\epsilon,c).
\]

The definition of \(f_a\) is independent of the representative precisely because the profile kernel is transition-stable. This gives

\[
T_a(K_p)\subseteq K_{f_a(p)}
\]

and exact reader agreement: **[CR-15.2](<C:/Users/devan/OneDrive/Desktop/Projects/Latent-Space-Reasoning/theory/CONTINUATION_REFINEMENT.md:735>) with \(\eta=0\)**.

There is no \(L\le1\) requirement. In fact, these hypotheses make equality of \(W\)-profiles equivalent to full registered behavioral equivalence on \(S\), although the numerical distances \(d_W\) and \(d_\infty\) can differ.

The converse needs qualification:

- If the realization sets are specifically the fibers of \(P_W\), their transition closure is equivalent to exact profile factorization.
- A general CR-15.2 realization system need not use those fibers. Its abstract state may remember distinctions absent from \(W\). Even an exact singleton-state realization of a countdown system does not make its immediate reader sufficient.
- At \(\eta>0\), CR-15.2 allows overlapping realization sets. Its invariant concrete–abstract relation gives the uniform \(2\eta\) bound. A one-step regression residual \(\delta\) does not construct that relation or inherit its uniform guarantee.

For approximate erasure, the direct relation is

\[
R_\tau=\{(x,y):d_W(x,y)\le\tau\}.
\]

On invariant \(S\), its greatest transition-invariant subrelation is

\[
\boxed{
R_\tau^{\mathrm{inv}}
=\{(x,y):\sup_{v\in A^*}d_W(T_vx,T_vy)\le\tau\}.
}
\]

This can fail to be transitive. It expresses the genuine lifetime requirement without promising a canonical approximate quotient.

**CR-15.10.3 What is used (prior art)**

| Prior art | What this draft uses—and what it does not establish |
|---|---|
| **Angluin \(L^*\)** | An earlier draft misnamed **consistency** as **closedness**. Consistency says equal rows have equal successor rows. Closedness says every boundary successor row has a representative among the proposed state rows. Both are needed for the finite table construction. A distinguishing pair here resembles a consistency witness; it is not automatically an \(L^*\) equivalence-query counterexample. A bounded neural panel supplies no equivalence oracle. [Angluin, §2.1](https://homepages.math.uic.edu/~lreyzin/papers/angluin87.pdf). |

| | |
|---|---|
| **Myhill–Nerode / Moore coalgebra** | Equality under all future observations, quotient transitions, and distinguishing continuations are established constructions. CR-2's bounded observations approximate that equivalence. Finite sampled stabilization does not establish a finite global behavioral quotient. The general systems formulation is standard coalgebra. [Rutten](https://ir.cwi.nl/pub/4802/4802D.pdf). |
| **Predictive state representations** | A profile of future-test predictions serving as sufficient state, with updates determined from that profile, is directly within PSR territory. The present deterministic-action formulation does not establish a small sufficient test set or generalization. [Littman, Sutton and Singh](https://proceedings.neurips.cc/paper/2001/file/1e4d36177d71bbb3558e43af9577d70e-Paper.pdf). |
| **Observable operator models** | Observable predictions and their recursive updates are established. OOMs additionally supply linear operator structure; the proposed arbitrary Lipschitz maps establish neither that structure nor finite rank. [Jaeger](https://www.ai.rug.nl/minds/uploads/oom_neco00.pdf). |
| **Approximate simulation/bisimulation** | Output tolerances plus invariant transition relations, and uniform behavioral guarantees derived from them, are established. The exact action-matching and coverage assumptions matter when identifying a particular construction as a bisimulation. [Girard and Pappas](https://www.georgejpappas.org/wp-content/uploads/2024/04/GP07-TAC.pdf). |

**No mathematical novelty is established here.** The propagation proof is elementary stability reasoning. A useful contribution could be a consequential observation family and a validated prediction or substitution rule in a real model. That remains unestablished; using established mathematics is entirely appropriate.

**CR-15.10.4 Real-model anchor (CR-9 data): licensed reading**

The [CR-9 reading](<C:/Users/devan/OneDrive/Desktop/Projects/Latent-Space-Reasoning/theory/CONTINUATION_REFINEMENT.md:215>) is **not licensed as "neutral is closed, heavy is not."**

A licensed sentence is:

> *On the reported Qwen3-1.7B-Base prompt panel, the three pair-family summaries showed small, nonzero discrepancies in the 11-bin immediate response law; these decreased after the neutral comment and increased after the reassignment-announcement comment, demonstrating continuation-dependent amplification at that observation resolution.*

The reported heavy amplification is approximately $2.6$–$13.2\times$. These are panel summaries, not uniform bounds over individual states.

The distinctions matter:

- Nonzero input differences cannot disprove exact profile determination. An exact successor function with sufficiently large sensitivity remains compatible with the observations.
- Pairwise ratios constrain possible $L,\delta$ combinations; they do not identify a Lipschitz constant or separate amplification from approximation error.
- Coarse TV is bounded above by full-law TV. Small 11-bin input TV does not establish small full-law input TV.
- $H$ is a **comment announcing reassignment**. It is different from CRC-0's actual reassignment action $R$.
- A neutral comment adds tokens and changes the readout context; its wording does not make it an identity action.

Never say:

- "The immediate-read family is closed under $N$."
- "These observations refute exact closure under $H$."
- "$L_N\approx1$ and $L_H\approx3$–$13$" as estimated global constants.
- "The model erased the presentation difference."
- "Presentation differences can safely be forgotten across arbitrary neutral steps."
- "This proves a general obstacle to structured reasoning or a model-wide algebra."

The simplest live rival is ordinary lexical/position-dependent readout sensitivity. The evidence does not require a deeper mechanism.

The intervention consequence is conditional: replacing the **complete registered state** by another state within the proved bound preserves the specified observations accordingly. It does not automatically cover a partial activation transplant, unmatched cache positions, or a differently typed prefix swap.

**CR-15.10.5 Existing-data reading and the enlarged-family test**

**For “does adding \(H\) make \(W\) closed under \(N,H\)?”: none from the retained CRC-0 artifact.**

The [save block](<C:/Users/devan/OneDrive/Desktop/Projects/Latent-Space-Reasoning/experiments/run_crc_0.py:562>) stores neither dense nor top-\(k\) laws, nor per-word distance matrices. The result directory contains only the 9,009-byte [summary file](<C:/Users/devan/OneDrive/Desktop/Projects/Latent-Space-Reasoning/experiments/results/crc_0/result.json>). The configuration’s storage description does not match the implementation.

Also, the historical closure loop tests single-action responses already included in the \(Q_1\) definition. It does not test successor \(Q_1\)-profiles. Its actual score of \(1\) means **zero tested cases and zero coverage**.

There is, however, a cheaper **one-sided witness check using retained summaries**.

Use the original \(\tau=0.01\). The runner creates a split event only from a shared \(Q_0\) component; `q0.all_cliques=true` establishes that every such pair had \(d_0<0.01\). Reject preservation of that tolerance under \(H\) if a same-variable event records `worst_action="H"` and post-action TV greater than \(0.01\).

Two stored events already meet this rule:

| Pair | Recorded input bound | Recorded post-\(H\) full-law TV |
|---|---|---|
| `d4_y_3_P0`, `d4_y_3_P1` | \(<0.01\) | \(0.0280138853\) |
| `d4_y_5_P0`, `d4_y_5_P1` | \(<0.01\) | \(0.0271364677\) |

These are same-variable comparisons with the same literal action and query. The cross-variable \(R\) witness is unnecessary and introduces action-typing questions.

The licensed conclusion is:

> *CRC-0’s recorded full-law witnesses violate preservation of the \(0.01\) immediate-response tolerance under the heavy comment on two same-variable presentation pairs.*

That is a reading of existing numerical evidence, not a newly run test or a refutation of exact profile closure.

If the missing distributions were recovered, the minimal enlarged-family test would use

\[
W_H=\{(\epsilon,\mathrm{read}),(H,\mathrm{read})\}.
\]

For each same-type pair, calculate

\[
d=\max(\operatorname{TV}_{\epsilon},\operatorname{TV}_{H}),\qquad
b_a=\max(\operatorname{TV}_{a},\operatorname{TV}_{Ha}),
\quad a\in\{N,H\}.
\]

At a locked tolerance, a pair with \(d\le\tau\) and \(b_a>\tau\) rejects tolerance invariance on the tested roots. No distinct eligible pairs means **inconclusive**, not pass. Numerical uncertainty must be handled by locked bounds before interpreting borderline cases.

Crucially, the runner stores action tuples in execution order: mathematical \(Ha\) corresponds to tuple **`(a,H)`**. Adding \(H\) to the input profile automatically removes its original witnesses; the substantive checks require the subsequent \(HN\) and \(HH\) responses. Passing them would still establish only a finite-panel result.

**CR-15.10.6. Locked direction: finite-question certification of interchangeability**

**Status.** ANALYTICAL_ONLY. Direction dialogue round 3 of 3, 2026-09-05. No model acquisition or runner implementation is authorized by this registration. The next cycle is one bounded analytical construction concerning interface-relative interchangeability. Real-model runs require explicit approval.

**Question and claim.** What can an inhabitant of a registered world certify about

\[
\omega_a^W(t)=
\sup_{\substack{x,y\in S\\d_W(x,y)\le t}}
d_W(T_ax,T_ay)
\]
using finitely many questions? Distinguish a finite enumerated pair panel, a global domain, and all-future interchangeability. Every result declares its domain, legal actions, channels and observation horizon.

**Analytical design.**

1. Derive the moduli for the countdown, doubling, CR-15.5 selective-write and CR-15.9 decaying-nuisance worlds under explicitly stated question families and pair domains. Distinguish exact profile sufficiency, positive-tolerance preservation, and selective preservation.

2. Prove the finite-panel bounding rule below.

3. State and prove the finite-observation obstruction for unrestricted deterministic worlds: without exhaustive coverage or additional structural assumptions, a finite transcript cannot exclude unobserved states or delayed distinguishing behavior.

4. Give one explicit sufficient additional premise permitting a useful upper bound. Identify which part of that premise finite questions establish and which part requires independent justification. Do not infer an invariant domain, inverse observability, or a global behavioral bound from sampled agreement.

For an exhaustive finite pair panel \(\mathcal P\), suppose valid bounds satisfy
\[
d_i\in[d_i^-,d_i^+],\qquad
b_i\in[b_i^-,b_i^+].
\]
Then
\[
\max_{i:d_i^+\le t}b_i^-
\;\le\;
\omega_{a,\mathcal P}^{W}(t)
\;\le\;
\max_{i:d_i^-\le t}b_i^+.
\]
Empty maxima are zero for this formula. Useful compression or interchangeability still requires distinct-pair nonvacuity. The rule’s validity is conditional on the stated bounds being valid enclosures.

**Deferred real-model interface.** The historical anchor is Qwen3-1.7B-Base, with full next-token-law TV primary and a fixed value-plus-OTHER reduction diagnostic. A 0.6B model is a separate experiment. Any acquisition must pin model and tokenizer revisions, numerical implementation, prompts and token IDs.

The complete carrier is the presented token history with execution and position metadata. Primary presentation comparisons use the same variable and value, compatible structural types, matched actual token positions, and common action/query token sequences. N is the neutral comment; H is the comment announcing reassignment; R is actual reassignment. H and R are not interchangeable action labels.

Use \(W_0=\{\epsilon\}\), \(W_H=\{\epsilon,H\}\), and diagnostic \(W_2=\{w:|w|\le2,\ w\in\{N,H,R\}^*\}\), with the registered read channel understood. In runner execution order,
\[
d_{W_H}=\max(D_{()},D_{(H,)}),\qquad
b_a^{W_H}=\max(D_{(a,)},D_{(a,H)}).
\]
Test \(a\in\{N,H\}\). Length-two data do not test successor \(W_2\)-profiles.

The historical 36-root panel is not an acquisition-ready positive test: its retained summaries contain no strictly \(\tau\)-close same-variable \(W_H\) pairs at \(\tau=0.01\). Repairing P2's outer function name, changing presentations, positions or model defines a new panel with unknown coverage. No historical result transfers automatically to that revision.

**Numerical and usefulness criteria.** Lock \(\tau=0.01\). For any later acquisition, let \(\nu\) be the maximum observed TV discrepancy across registered three-way repeated evaluations and cached-versus-full comparisons. Set

\[
m=2\max(10^{-6},\nu).
\]

If \(m>\tau/100\), numerical adjudication is INCONCLUSIVE. Otherwise form clipped operational intervals by adding and subtracting \(m\) from each estimated distance. These are empirical reproducibility guards, not certified bounds on exact-arithmetic model probabilities.

A robust witness satisfies \(d_i^+\le\tau\) and \(b_i^->\tau\). One such pair suffices to refute preservation on the declared panel. Positive usefulness requires at least five distinct robust-close pairs spanning at least five \((\mathrm{variable},\mathrm{value})\) task blocks. This is a coverage requirement, not a significance threshold.

Report pair identities, eligible and excluded counts, absolute discrepancies, threshold margins and task-block coverage. Ratios are diagnostic only and are omitted when the denominator is not resolved above the numerical floor. Do not form equivalence classes by transitive closure of tolerance edges.

Any later valid-program acquisition requires at least 95% correct full-vocabulary top-one reads on the 36 roots, declared action competence checks, and valid tokenization boundaries. These next-token-law measurements have no generation-termination statistic. Save dense normalized laws and per-word full-TV matrices; top-k summaries are optional additions.

**Predictions and rivals.** P predicts that every eligible \(W_H\)-close pair preserves the tolerance under N and H. This is a finite-panel safety prediction, not a mechanism claim.

Lock \(\epsilon_R=\tau/5=0.002\). For each declared action/type stratum, the affine rival permits \(g,c\ge0\) with absolute residual at most \(\epsilon_R\). With guarded intervals, reject compatibility only when there is no common \(g,c\) satisfying, for every registered pair,

\[
b_i^- -\epsilon_R\le g d_i^+ +c,
\qquad
g d_i^-+c\le b_i^+ +\epsilon_R.
\]

Do not reject using the coefficient of variation of \(b/d\).

Test the length-only rival separately on the same pairs and input profiles, using filler F matched to H's actual token increment and resulting positions. Freeze filler selection without inspecting response outcomes. The rival predicts

\[
|b_H^W-b_F^W|\le\epsilon_R.
\]

A robust violation rejects this restricted account only. Neither restricted rejection establishes a nonlexical mechanism.

A consequential P-versus-rival experiment additionally requires a prospectively reserved disagreement set: P predicts preservation while an independently calibrated rival envelope predicts a split. If no nonvacuous disagreement set exists, do not label the acquisition discriminating.

**Verdicts.**

- `WITNESSED`: at least one valid robust counterexample.
- `TOLERANCE_PRESERVED_ON_PANEL`: complete valid endpoints, required nonvacuity, and \(b_i^+\le\tau\) for every potentially close pair \(d_i^-\le\tau\). This is an operational finite-panel verdict, not a global or lifetime theorem.
- `INCONCLUSIVE`: insufficient coverage, unresolved boundaries, invalid interface, inadequate numerical reproducibility, or missing endpoints.
- Report `AFFINE_RIVAL_REJECTED` and `LENGTH_ONLY_RIVAL_REJECTED` separately. Otherwise report compatibility or inconclusiveness; absence of rejection is not support.

A useful positive result may motivate one bounded question-selector prototype with explicit coverage, question-cost and unused-endpoint prediction obligations. Persistent or mixed witnesses end this empirical refinement attempt without threshold tuning or automatic horizon expansion. No outcome alone licenses a minimal sufficient state, a closed quotient, learned overwrite, or native mathematical novelty.

**Analytical completion criterion.** Deliver the contrast-world derivations, the finite-panel bounding proposition, the unrestricted-world obstruction, and one explicit sufficient certification premise with its evidence obligations. No new empirical apparatus is required for this cycle.

**CR-15.10.7. Analytical deliverables of CR-15.10.6 (audit #41 corrections applied)**

Status: REVISED after audit #41 (2026-09-05). Retained: finite-panel enclosures (2), corrected declared-domain moduli (1), the refinement identity (5), and the conditional routes in (4). Withdrawn: the original obstruction theorem, the saturation impossibility claim, the global rank/inverse bound and both dimension extrapolations. Every result below is established mathematics on declared domains; none is a real-model finding.

Notation as in CR-15.10: $d_W$, $\omega_a^W(t)$, reachable set $S$, TV

on Bernoulli laws equals $|p-q|$.

**(1) Moduli of the contrast worlds.** Each row declares its action-invariant comparison domain and question family. These are not automatically the reachable states from one fixed initial state. Restricting a domain to a smaller orbit can lower its modulus. Below, $0\le t\le1$.

| World and declared domain | Questions | Correct modulus |
|---|---|---|
| Coordinate replacement with an **additional product-max response metric assumption** | Coordinate-factor immediate reads | $\omega(0)=0,\ \omega(t)\le t$; addressed fiber erased exactly |
| Decaying nuisance on $\{0,1\}\times[0,1]$, $0<\delta\le1$ | Bit and $\mathrm{Bern}(\delta x)$ | $\omega(t)=\frac12\min(t,\delta)$ |
| Doubling on all of $[0,1]$ | $\mathrm{Bern}(x)$ | $\omega(t)=\min(1,2t)$ |
| Countdown on all $\{0,1\}\times\mathbb N_0$, step totalized at zero | All questions through finite depth $h$ | $\omega(t)=1$ |
| Cyclic counter on $\{0,1\}\times\mathbb Z_m,\ m\ge3$ | $W_0$ | Exact finite maximum below; $\omega(0)>0$, but only $O(1/m)$ |
| Same cyclic counter | $W_1$ | $\omega(0)=0$ for **every $m\ge3$**; $\omega(t)\le\min(1,3t)$ |
| CR-15.5 on its full invariant square | Both immediate reads | $\omega(t)=t$ globally; $\theta t$ on the addressed fiber |

The first row does **not** follow from CR-15.1 alone: that section establishes a product of sets with an action, not a product metric. Counterexample: $b,s\in\{0,1\}$, overwrite $s$, readers $r_1(b,s)=\mathrm{Bern}(s)$, $r_2(b,s)=\mathrm{Bern}((1-s)b)$. States $(0,1),(1,1)$ have identical immediate profiles; overwriting $s\leftarrow0$ separates them by one. Addressed-fiber erasure remains true; general immediate-profile nonexpansiveness does not.

Put $\alpha=2\pi/m$, $c_j=(1+\cos(j\alpha))/2$, and

$$
C_k(j,\ell)=|c_{j+k}-c_{\ell+k}|.
$$

Since the input bits can be chosen equal and the common write overwrites them,

$$
\omega^{W_0}(t)=\max_{C_0(j,\ell)\le t}C_1(j,\ell),
$$

$$
\omega^{W_1}(t)=
\max_{\max(C_0,C_1)\le t}\max(C_1,C_2).
$$

For $m\ge3$,

$$

\omega^{W_0}(0)

=\sin\alpha\max_j|\sin(j\alpha)|>0.

\]

In particular this is at most \(\sin\alpha\), so it is not bounded below by an order-one constant as \(m\) grows.

>

Two consecutive cosines determine the phase for every \(m\ge3\), because

\[

\sin(j\alpha)=

\frac{\cos(j\alpha)\cos\alpha-\cos((j+1)\alpha)}

{\sin\alpha}.

\]

There is no odd/even obstruction. When \(2j\equiv-1\pmod m\), the proposed symmetry sends \(j\) to itself, not to a distinct indistinguishable phase.

>

Furthermore,

\[

c_{j+2}=2\cos\alpha\,c_{j+1}-c_j+1-\cos\alpha,

\]

hence

\[

\omega^{W_1}(t)

\le\min\{1,(1+2|\cos\alpha|)t\}

\le\min(1,3t).

\]

Thus the gain is bounded, including near cosine turning points. Amplification nevertheless occurs: for \(m=6\), equal-bit states with phases \(0,5\) have input distance \(1/4\) and successor distance \(1/2\).

The other derivations survive on their declared domains. Doubling attains its bound using \(0\) and \(\min(t,1/2)\). Countdown uses \((0,h+1),(1,h+1)\). CR-15.5 attains the global bound by varying the preserved coordinate and the fiber bound by varying the addressed coordinate.

For decaying nuisance, the post-write distance is exactly \(\delta|x-y|/2\). The full interval supplies every required separation. A single initial-state orbit has dyadic nuisance coordinates and need not attain the continuous formula.

**(2) Finite-panel bounding proposition.** Let \(\mathcal P\) be a finite set of pairs with valid enclosures \(d_i\in[d_i^-,d_i^+]\) of \(d_W(x_i,y_i)\) and \(b_i\in[b_i^-,b_i^+]\) of \(d_W(T_{ax_i},T_{ay_i})\). Define the panel modulus \(\omega_{a,\mathcal P}^W(t)=\max\{b_i:d_i\le t\}\) (empty max \(=0\)). Then

\[

\max_{i:\,d_i^+\le t}b_i^-\ \le\ \omega_{a,\mathcal P}^W(t)\ \le\ \max_{i:\,d_i^-\le t}b_i^+ .

\]

Proof. Every pair with \(d_i^+\le t\) is eligible, so its true \(b_i\ge b_i^-\) is a lower bound. Every eligible pair has \(d_i\le t\), hence \(d_i^-\le t\), and its true \(b_i\le b_i^+\). \(\square\)

The panel modulus lower-bounds the domain modulus: \(\omega_{a,\mathcal P}^W(t)\le\omega_a^W(t)\) whenever \(\mathcal P\subseteq S\times S\). Nothing in the proposition bounds \(\omega_a^W\) from above; valid intervals bound a panel modulus, they do not necessarily determine it exactly (audit #41).

**(3) Finite response-transcript obstruction.** Fix finite nonempty action and channel sets, with total deterministic actions and unconstrained Bernoulli response laws. Let \(W\) be a finite nonempty question family. A realizable finite response-only transcript specifies finitely many rooted response trees, supplies no independently verified state identities or exhaustive transition table, and permits extensions beyond the observations.

For each action \(a\), there exists a consistent completion with additional reachable states and \(\omega_a^W(0)=1\). Consequently such a transcript cannot certify a global upper bound below one or exhaustive reachability. It need not admit a completion with \(\omega_a^W(0)=0\).

**Proof.** Unroll the observed trees without identifying response-equal nodes. Beyond all recorded observations, choose two reachable nodes with disjoint response neighborhoods covering \(W\cup aW\); for a unary alphabet, choose sufficiently separated positions on one path. Choose a longest question \((w,c)\in W\). Then \((wa,c)\in aW\setminus W\). Assign equal laws to the two nodes on every question in \(W\), and opposite Bernoulli endpoint laws at \((wa,c)\). Complete unspecified transitions and responses arbitrarily. The transcript is unchanged, while the new pair has input discrepancy zero and successor discrepancy one. \(\square\)

This states the obstruction without the withdrawn zero-world assertion (audit #41: a depth-one transcript recording \(r(x)=r(y)=\mathrm{Bern}(0)\), \(r(T_ax)=\mathrm{Bern}(0)\), \(r(T_ay)=\mathrm{Bern}(1)\) forces \(\omega_a^W(0)=1\) in every consistent world). Empty families, restricted channels, independently known finite state identities, and structurally restricted worlds require separate statements. This is established finite-observation underdetermination (Angluin §2.1, Theorem 1; Rutten).

**(4) Three sufficient premises for an upper bound, and what finite questions contribute to each.**

(4a) *Finite exact orbit* (CR-15.8/15.9). Suppose the orbit for the same registered action alphabet has at most \(N\) exact behavioral states. Let \(q\) be the number of its immediate-response classes. Horizon equivalence is full behavioral equivalence by depth \(N-q\): every strict refinement increases the class count, while equality of consecutive partitions implies permanent stabilization.

A representative set containing the initial state and closed under every action modulo this proved equivalence exhausts the behavioral orbit. Finite actions and channels, exact response evaluation, and decidable equality permit this finite check, including successor profiles. For finite \(W\), evaluating every representative pair computes its modulus exactly.

A known lower bound \(\underline q\le q\) gives the safe depth \(N-\underline q\). Exhaustion here is of behavioral states, not necessarily concrete carrier states. The state bound and exact-evaluation assumptions require independent justification.

A bound on a write-only orbit does not cover an enlarged action alphabet automatically.

(4b) *Contraction with two-sided observability* (surgeon route). Premise: a carrier metric \(\varrho\) on an action-invariant set \(S\) with (i) \(\varrho(T_ax,T_ay)\le\kappa_a\varrho(x,y)\); (ii) full-profile Lipschitz control: for every \((w,c)\in W\) and \(u,v\in S\), \(D_c(r_c(T_wu),r_c(T_wv))\le L\varrho(u,v)\), equivalently \(d_W(u,v)\le L\varrho(u,v)\) (immediate-reader Lipschitz control is not enough); (iii) inverse observability: a finite family \(W_*\subseteq W\) and \(\lambda\) with \(\varrho(x,y)\le\lambda\,d_{W_*}(x,y)\) uniformly on \(S\). Then

\[
d_W(T_ax,T_ay)\le L\varrho(T_ax,T_ay)\le L\kappa_a\varrho(x,y)\le L\kappa_a\lambda\,d_{W_*}(x,y)\le L\kappa_a\lambda\,d_W(x,y),
\]

so \(\omega_a^W(t)\le\min\{1,L\kappa_a\lambda\,t\}\), and \(L\kappa_a\lambda\le1\) is sufficient for tolerance preservation. All constants must hold uniformly on the declared domain. Finite questions establish none of (i)-(iii); carrier measurements can refute (i), (ii) or (iii), and witnesses can refute the conclusion. (iii) is the premise CR-15.3 lacked: CR-15.3 turns small carrier separation into small responses; (iii) turns small responses into small carrier separation. Without (iii), CR-15.3 bounds only pairs inside one realization ball, never every \(W\)-close pair.

For \(0<\delta\le1\), globally valid scalar constants in the product-max carrier metric are

\[
\kappa=\tfrac12,\qquad L=1,\qquad
\lambda=\max(1,1/\delta)=1/\delta.
\]

Their generic product gives the loose coefficient \(1/(2\delta)\). The sharper channel-specific calculation is

\[
d_W(F_v(b,x),F_v(b',y))
=\tfrac{\delta}{2}|x-y|
\le\tfrac12d_W((b,x),(b',y)).
\]

On equal-bit pairs this is equality before domain clipping. On the full product domain it yields

\(\omega(t)=\frac12\min(t,\delta)\).

(4c) *Closed invariant relation* (CR-15.2). Independently established membership in a common realization set, uniform abstract-reader accuracy, and transition closure imply successor discrepancy at most $\min(1,2\eta)$. Agreement on finitely many responses alone does not establish membership. A global modulus bound additionally requires every eligible $W$-close pair to belong to a common certified realization set. That coverage requirement is a sufficient observability condition, but is not automatically equivalent to the metric inequality in (iii).

Proposition (what a denizen can certify). For finite $W$, exact response access determines finite-panel moduli; valid enclosures give the bounds in item (2). Witnesses supply global lower bounds and can refute specified observable implications of candidate premises. Response-only finite transcripts cannot establish a nontrivial global upper bound over the unrestricted completion class of item (3). Conditional upper bounds remain possible with independently justified completeness or structural premises, as in (4a)–(4c). Finite stochastic samples need not determine exact response laws or exact panel moduli.

**(5) Refinement modulus (definition, proposal).** For the tower $W_h$ of words of length $\le h$,

$$
\rho_h(t)=\sup\{d_{W_{h+1}}(x,y):x,y\in S,\ d_{W_h}(x,y)\le t\}.
$$

Since $W_{h+1}=W_h\cup\bigcup_a aW_h$ and $d_{W}(T_ax,T_ay)=d_{aW}(x,y)$, writing $E_t=\{(x,y):d_{W_h}(x,y)\le t\}$ one has $\rho_h(t)=\max\{\sup_{E_t}d_{W_h},\ \max_a\omega_a^{W_h}(t)\}$, so the tower's quantitative refinement rate is the worst action modulus at that level (up to the trivial first term, which is $\le t$). Level $h$ is exactly consistent iff $\rho_h(0)=0$ and preserves tolerance $\tau$ iff $\rho_h(\tau)\le\tau$. This replaces CR-5's class-count rate (which needs finite cardinalities, audit #39) by a tolerance-indexed rate defined for every world. On a finite orbit of $N$ places, $\rho_h(0)=0$ for $h\ge N-|Q_0|$; tolerance stabilization is not implied at the same level (cyclic counter, $m=6$): equal-bit phases $0,5$ have input distance $1/4$ and successor distance $1/2$). This does not mean a finite world can avoid numerical stabilization forever: its unordered-pair transition system is finite, so a sufficiently large finite horizon attains $d_\infty$, after which every tolerance is preserved. The modulus is a useful classical definition, not a new latent-space structure.

**Completion status against CR-15.10.6.** Items (1)-(4) delivered in draft; the sufficient premise chosen for (4) is (4b), because it is the one whose missing half (inverse observability) is exactly what the certificate lane lacked, and it reproduces the constructed-world moduli. Evidence obligations for any future use of (4b): $\kappa_a$, $L$, $\lambda$ as surgeon certificates on a verified invariant set; the denizen contributes witnesses and panel consistency only. Stated plainly, (ii)+(iii) say the registered reader is bi-Lipschitz on the invariant set, which is surgeon-only and is expected to FAIL for readers with argmax or saturating softmax outputs; this is where the premise is most likely to break on learned cells. Nothing here is a real-model finding. Self-critique of this draft: internal/codex_transcripts/cr15107_self_critique.md.

**(6) Saturation and inverse conditioning (audit #41 replacement).** Let $p=\sigma\circ g$, with $g$ $L_g$-Lipschitz and $L_g>0$. Globally,

$$
|\Delta p|\le\tfrac14L_g\varrho.
$$

If both compared logits lie in the same half-line $[G,\infty)$ or $(-\infty,-G]$, then

$$
|\Delta p|\le\sigma'(G)|\Delta g|
\le e^{-G}L_g\varrho.
$$

On a nontrivial same-sided domain, any valid finite inverse constant therefore satisfies

$$
\lambda\ge e^G/L_g.
$$

Distinct states with identical logits preclude a finite inverse constant. Finite saturation alone does not.

The lower bound on $\lambda$ does not establish an intrinsic lower bound $L\kappa\lambda\ge\kappa e^G/4$, because $L_g/4$ is an available upper bound on reader sensitivity, not a lower bound on its best Lipschitz constant.

The same-sided condition matters: logits $-G,+G$ do not satisfy the exponential secant bound. Counterexample to any impossibility reading: $S=[0,1]$, $g(x)=G+x$, $T(x)=x/4$; then $L=\sigma'(G)$, $\lambda=1/\sigma'(G+1)$, $\kappa=1/4$, and $L\kappa\lambda<e/4<1$: the reader can be arbitrarily saturated while the transfer certificate remains useful.

The saved floating-point aggregates report nearly saturated reads and paired TV about $1.4\times10^{-8}$. They do not certify per-state logits or carrier distances. Both small and substantial retained carrier differences remain possible; saturation or a many-to-one reader is an explanation, not an established mechanism. No diagnostic is authorized or queued by this analysis.

Useful questions must separate relevant distinctions with adequate conditioning on the declared domain. Unsaturated responses are neither necessary nor sufficient: a constant probability $1/2$ has maximal entropy and supplies no state information. Entropy alone is not a question-selection criterion.

Order-one carrier separation is mathematically compatible with TV of that scale ($g(x)=18+x$), $x\in\{0,1\}$ gives separation one and probability difference about $9.6\times10^{-9}$); that example does not identify the actual cell's separation. No distance threshold is a mechanism-confirmation rule.

**(7) Rank: a local necessary condition only (audit #41 replacement).** Assume $P$ is continuously differentiable, the carrier domain contains an open $d$-dimensional set, and $\varrho(x,y)=\|x-y\|_2$. For scalar binary questions,

$$
d_{W_*}(x,y)=\|P(x)-P(y)\|_\infty.
$$

Uniform inverse observability implies, at every interior point,

$$
\|J_P(m)v\|_\infty\ge\|v\|_2/\lambda.
$$

Hence $J_P(m)$ has rank $d$ and $K\ge d$. On a smooth lower-dimensional carrier, the corresponding statement concerns its tangent dimension. Arbitrary metrics or discrete sets do not justify this inference.

Injectivity alone does not imply full differential rank. Full differential rank alone does not supply a global inverse bound. Define

$$
\beta=\inf_{x\ne y\in S}
\frac{\|P(x)-P(y)\|_\infty}{\|x-y\|_2}.
$$

Finite global inverse observability holds precisely when $\beta>0$, with optimal constant $1/\beta$.

Injectivity with a uniformly bounded-below Euclidean least singular value does not bound the inverse constant: $P(t)=(\tfrac12+\tfrac14\cos t,\tfrac12+\tfrac14\sin t)$ on $[0,2\pi-\varepsilon]$ is injective with least singular value $1/4$ everywhere, yet its endpoints are $\approx2\pi$ apart with response distance $O(\varepsilon)$. The pointwise inequality $s_{\min}(J_P)\le\max_k\sigma'(g_k)\,s_{\min}(J_g)\le e^{-G}s_{\min}(J_g)$ holds under pointwise saturation (Euclidean singular values) as an inequality; finite logits leave the diagonal factors positive, so saturation alone does not change exact rank. The nonlinear observability rank condition (Hermann-Krener, Thm 3.1) is local and uses derivatives of output continuations; it is not a global inverse-Lipschitz theorem.

Linear PSR/OOM dimension is the rank of the history-by-test matrix, equivalently the dimension of the appropriate predictor-function span. A core test set supplies a basis from which all test predictions can be recovered. This is different from local Jacobian rank or nonlinear carrier dimension. An arbitrary locally full-rank family need not be globally sufficient, linearly spanning, or uniformly well-conditioned. Additional questions can improve conditioning or resolve distant ambiguities. No equality between these dimensions is established here. (Littman-Sutton-Singh §1; Singh-James-Rudary §§4-5; Jaeger §5.)

The deferred $W_H$ family contains two full next-token-distribution questions, not two scalar binary observations. A distribution over $V$ outcomes can supply up to $V-1$ scalar coordinates. Moreover, presented histories form a discrete, variable-length domain whose relevant smooth dimension has not been established. Therefore question count alone proves no rank deficiency or impossibility of premise (4b). The registered panel supports only its stated finite-panel conclusions because global coverage and structural premises remain unproved.

For the sealed reader at fixed address and zero bypass, reversing the legend swaps the same two candidate scores. Its immediate profile therefore depends on one scalar score difference and has differential rank at most one, with rank one wherever that score difference has nonzero gradient. This rules out carrier-metric inverse observability on an open 16-dimensional domain. It does not rule it out on every finite or lower-dimensional reachable set, nor rule out richer continuation families or global behavioral guarantees through CR-15.2/15.3 realization sets. Recovering behaviorally irrelevant carrier coordinates is unnecessary for behavioral overwrite.

**Audit #41 summary (applies to this whole subsection).** Finite-panel enclosures, corrected declared-domain moduli, and the refinement identity are retained. Response-only finite transcripts cannot establish a nontrivial global bound over unrestricted extensions;

independently justified completeness or structural premises can. The contraction route requires Lipschitz control of full question profiles and a uniform inverse bound on the declared carrier domain. Saturation can degrade conditioning without making inversion impossible. Local rank does not establish a global inverse bound or PSR dimension. Neither the saved cell's retained-history mechanism nor \(W_H\)'s rank has been established. No new learned realization, generalization result, or native mathematical novelty follows.

## CR-16. Architectural restrictions of the transformer world and their consequences for registered questions

Status: AUDITED BACKGROUND / RESTATEMENT (audit #42, 2026-09-06). Corrected identities clarify existing controls. No substantive change to the locked interface or new real-model result was established. Every claim carries its domain, positional scheme, normalization and epsilon, arithmetic model, and observation scope. Textbook facts are cited, not claimed. The block passes only if at least one consequence below changes the registered question families \(W_0,W_H,W_2\) of CR-15.10.6.

**Objects.** A presented history is a token-ID sequence with position IDs and execution metadata. The registered channel is the next-token law at the final position. Reader invariance \(r(gx)=r(x)\), commutation with every registered append \(gT_a=T_ag\), and common legality are sufficient for equality of all registered future responses. Literal commutation on the carrier is not necessary: corresponding successors may instead be behaviorally equivalent. Equality of one internal component alone establishes neither condition.

**16.1 Origin relabeling under rotary attention (exact; known).** For fixed-frequency RoPE on queries and keys, \((R_{p_i+s}q_i)^\top R_{p_j+s}k_j =q_i^\top R_{p_j-p_i}k_j\) (Su et al., RoFormer, eq. (16); the whole-stack invariance is a conditional corollary). Hence a common translation of all position IDs preserves the complete forward output, provided tokens, order, attended set, masks and biases are translation-compatible, values and residual inputs carry no absolute-position channel, positionwise operations and the reader ignore absolute IDs, RoPE frequencies are fixed, and arithmetic is exact. Scope: origin relabeling only; it says nothing about prepending tokens or moving content relative to BOS; additive absolute embeddings break it; dynamic position scaling, position-dependent value maps, and origin-anchored cache or window rules need separate analysis; floating point does not guarantee bitwise equality. On a carrier with canonical positions, independent origin relabelings are not distinct admissible presentations; this supplies no additional history identification. Consequence for CR-15.10.6: none beyond removing a presentation redundancy that the locked interface never used.

**16.2 Causal site-locality (exact).** With prefix-local input construction, fixed positional configuration, strictly causal attention, positionwise normalization and MLPs, and no other future-dependent path, the activation at position \(q\) at every layer depends only on the prefix through \(q\) (induction over layers; either norm placement; absolute or relative positions). Qualifications: hold token IDs fixed (appending raw text can re-tokenize a boundary); length-dependent RoPE reconfiguration or sequence-wide preprocessing violates the premise; an earlier site cannot update in response to a later write but can encode information from which a later query determines that the write is dead; appending changes the read position, so old-site invariance does not imply next-token-law invariance.

**16.3 Normalization: local identities, no licensed history quotient.** For \(c>0\), wherever defined,

\[

\mathrm{RMSNorm}_\epsilon(cx)

=\gamma\odot x/\sqrt{\|x\|^2/d+\epsilon/c^2}.

\]

Positive scaling is a general symmetry at \(\epsilon=0\) on nonzero inputs, but not generally at positive epsilon. LayerNorm is invariant under shifts along \(\mathbf1\) wherever defined; its general positive-scale symmetry likewise requires zero epsilon and nonzero variance.

For \(B(x)=x+f(N(x))\), the general identity is \(B(cx)=cx+f(N(cx))\). If \(N(cx)=N(x)\), this becomes \(cx+f(N(x))\), which need not equal or be proportional to \(B(x)\). Thus local normalization symmetry does not imply whole-stack scale symmetry or guarantee that later observations distinguish scales.

In a pure pre-LayerNorm stack, with every non-residual branch using normalized inputs, unchanged masks and metadata, and a final LayerNorm before the sole reader, per-token shifts \(b_i\mathbf1\) propagate unchanged through residual paths and disappear at the reader. This does not establish distinct reachable histories realizing those shifts. No ray quotient of presented histories is licensed.

**16.4 Attention aggregation (exact identity; no sequence-level

identification).** At a fixed query, \(A(q)=\sum_je^{s_j}v_j/\sum_je^{s_j}\)

is invariant under joint permutation of already-computed scores and values

(with relative positions attached to their content). Deeper keys and values

already encode ordered prefix information; equal attention outputs do not

give equal residuals, caches, or futures; a multiset of (token, position)

pairs with distinct positions already fixes the placement. Without

positions and without a causal mask, unmasked self-attention is permutation-

equivariant (Yun et al., Claim 1 and Appendix A; their formal architecture omits normalization, and shared positionwise normalization preserves equivariance by a separate elementary argument; unmasked equivariance does not imply invariance of a fixed final-position read); a causal mask breaks general permutation symmetry.

Consequence: no license to collapse reordered histories, paraphrases,

\(N/H\), or \(H/R\).

**16.5 Resource-bounded blindness (cite; scope separately).** Exact

indistinguishability, vanishing response separation, and computational

complexity are three different statements. Hahn's Lemma 5 bounds the change of the final activation by \(O(1/n)\) when one input symbol at \(i<n\) is changed, under its fixed soft-attention setting, bounded input and positional representations, bounded logits, Lipschitz updates, and normalization over all positions. A uniformly Lipschitz law-valued readout transfers the bound to response laws. This is not an append-operation bound or a bound for changing the final input symbol; its rate requires separate justification for causal stacks. Vanishing separation does not preclude correct argmax with vanishing margin.

Merrill and Sabharwal's Theorem 2 and Corollary 2.1 place transformers in their fixed-depth, log-precision computational model within logspace-uniform \(\mathrm{TC}^0\). Parity belongs to \(\mathrm{TC}^0\), so this upper bound supplies no parity impossibility; neither does it establish parity capability for a particular transformer. Fixed precision, log precision and exact arithmetic are distinct assumptions.

Liu et al. construct length-\(T\) simulators with \(O(\log T)\) depth for arbitrary finite semiautomata and depth independent of \(T\) for solvable semiautomata. Their constructions permit length-dependent resources, including width and weight magnitudes; they do not establish unbounded-length success of one fixed pretrained checkpoint.

The project's own restricted obstruction is the paired-pool fidelity lemma (CR-15.6, eq. 15.34); it is not a prohibition on last-write computation. If, for the same registered question \(w\), the intended laws at \(x,y\) have TV separation \(\Delta\), the model laws have separation at most \(\delta_n\), and each endpoint has TV error at most \(\eta\), then \(\Delta\le2\eta+\delta_n\). No architecture-specific \(\delta_n\) for the locked interface is established here.

**16.6 Appended-token offset identity: rationale for existing controls (audit #42 replacement).** Assume token-ID concatenation preserves the prefix, position IDs are consecutive with unit spacing, positional configuration is fixed and prefix-local, and evaluation is deterministic and causal under the hypotheses of 16.2. For every earlier site \(j\le n\) and layer \(\ell\),

\[

h_j^\ell(xB)=h_j^\ell(x),\qquad

(p_{n+k}-p_j)-(p_n-p_j)=k.

\]

The second equality is an index identity, independent of the appended token identities. It does not imply a nonzero or content-independent attention or response effect.

Attention can be partitioned into sums over earlier and new sites at each head. Both sums generally depend on appended content through the new query and softmax denominator. New-position residual and MLP paths also contribute. This partition is not an independent causal decomposition of the full stack.

For a common appended read template, use actual serialized token increments and positions; recomputed query-template sites are not frozen prefix sites. Raw-text boundary changes and positional reconfiguration require separate treatment.

Retain CR-15.10.6's existing H/F comparison on the same pairs and input profiles, with matched actual token increments and positions and response-independent filler selection. Rejection excludes only the registered restricted rival; subtracting scalar TV effects does not identify a semantic mechanism. A \(W_H\) split of a \(W_0\)-close pair alone does not identify H-specific semantics.

An attention intervention establishes independence only when it blocks every relevant directed path from the varied inputs to the reader, with remaining inputs and metadata matched. Masking does not generally preserve the original weights on unmasked sites. Historical CEG-1 RELAY-CUT blocks attention from positions at or after `live_start` to `dead_span`; its audited pairwise zero was already explained by graph disconnection.

Match or stratify actual increments and positions, but do not treat equal length as a shared additive response component. These observations explain existing controls and change none of \(W_0,W_H,W_2\). The substantive-consequence gate is not met.

**Licensed sentence (audit #42).** With fixed tokenization, consecutive positions and prefix-local causal evaluation, appending \(k\) tokens preserves earlier activations and increases final-query-to-prefix offsets by \(k\); these facts justify already-registered matching controls but neither decompose content effects nor establish new behavioral identifications or native latent mathematics.

# Vol 7 - Theory Corpus III: Cumulative Capability Acquisition (S1-S65)

# Cumulative Capability Acquisition

Status: current direction preserved; research PAUSED by user request on 2026-09-14.
No experiment is running or queued. Resume only when the user asks; docs/HANDOFFS.md
is the restart entrypoint. The research mission is unfinished.
The working definitions and evaluation progression below are proposals, not
established theorems, demonstrated capabilities or an approved run specification.

## Current decision map (strategy checkpoint, 2026-09-14)

The target is **repeated useful acquisition with established capabilities retained**.
Reusing prior preparation is one important approach and potential benefit; learning
to make later admissions easier is a stronger optional claim. A usable contribution must survive its
interface and participate in the intended computation. No single shared geometry
or cumulative architecture has been selected; S37's preflight is parked. These distinctions organize the
notebook; they are not a compulsory sequence of experiments.

| Decision | What must be known | What would change the approach |
|---|---|---|
| What can the donor supply? | Actual callable/exported resource and permitted inputs, S1/S10/S12 | Saved vectors cover particular inputs; new questions can require a callable model or a newly learned export |
| Why is the contribution useful? | Missing information, more accessible computation or cheaper realization, S13/S18/S19 | Different benefits require different controls; information novelty is not required for every acquisition |
| What can the receiver do with it? | Competent read, update, comparison, verification or other declared operation, S8/S11/S14 | Readout success does not establish reusable state changes; the inference procedure may carry the reasoning |
| What makes two ports interchangeable? | Preserved task-relative responses and legal continuations within declared tolerances, S5/S7/S14 | Matching geometry alone cannot decide operational substitution |
| What changes when the system grows? | New distinctions, calibration and compatibility with old operations, S2/S15/S17/S20 | A fixed interface may need extension; incompatible demands need an explicit policy rather than a retention promise |
| What is reused across acquisitions? | Integration procedure, retained preparation, new teaching and fresh-input access, S2.2/S28–S31 | Reusing interpretation differs from retaining weights; incremental fitting and direct distillation are serious alternatives, while future-operation reuse differs from anticipated multitask training |
| What is retained, and at what cost? | Old and joint task behavior, donor dependencies, acquisition and recurring costs, S4/S13/S19 | Keeping a donor and removing it are separate branches; retention by snapshots has a resource cost |

**Decisive empirical unknown:** can a donor's useful distinction or operation
contribute to a joint task through an affordable interface while established
uses remain adequate? Check each component's competence in its assigned role;
the donor need not outperform the receiver on the whole task alone (S13).
Receiver adaptation is allowed when declared and attributed. A frozen receiver
tests strict interchange, not all acquisition. Evidence for one interface is

local, not a universal law or a finished cumulative system.

**Current evidence boundary:** source and implementation studies now extend through S64, with local S58/S62/S65 results. Sources supply concrete trained reasoning, compressed-context reading, stitching and separately prepared contributor interfaces. None of the inspected results establishes the full repeated-acquisition contract below. Published precedents, local results and untested combinations must remain separate.

| Mission requirement | Strongest relevant evidence here | Still not established |
|---|---|---|
| Use a pretrained contributor in another computation | External constructive interfaces and joint-use precedent, S28/S30/S39/S40 | Local useful donor contribution under an adequate joint task and serious direct control |
| Reason using retained representations under later questions | Prepared compressed-context consumer and its released conditioning path, S49 | A predicted donor-response export usable by that consumer; independent-donor memory composition |
| Add useful B while retaining established A | External semantic/spatial merger with original-task evaluations, S50; retention constraints, S7/S8/S13/S32 | Local useful acquisition; donor-matched semantic retention and joint-operation attribution in the reference episode |
| Add C while reusing earlier preparation | Incremental-learning comparators and separately prepared interface precedent, S28-S31/S40 | An observed later acquisition with charged repair and retained A/B/joint uses |
| Retire a donor while retaining useful fresh-input behavior | S58: correct pseudo-labels improve a frozen-feature head on held-out images after teacher removal; external recipes S30/S42/S49 | Broader operations, new backbone knowledge and successive acquisitions; S58 is a limited species readout |
| Discover effective native latent mathematics | Conditional operational constraints and scoped empirical diagnostics | A law predicting useful interventions or composition in real learned spaces beyond the tested scaffolding |

Local accounting is nine probe blocks, 666 recorded forward calls plus 1–16 unrecorded first-attempt S65 calls (total 667–682), 2400 linear-head optimization steps and 45 S62 ridge-reader preparations; no GPU. S58 is a bounded teaching positive with independently reproduced predictions. S6/S21/S22/S26 are scoped negatives; S37 has two failed attempts and zero scored forwards. S47 demonstrates a sufficient direct lexical/section remedy on its small structured panel, then closes without a model probe. S43 separately inspects stored external responses. None demonstrates cumulative acquisition or an intrinsic inability of pretrained donors to contribute. Exact receipts remain in the ledger and result sections.

The mathematical aim is an economical operational language for identity, substitution, extension and effort. Ordinary mathematics is useful scaffolding. The test is whether these definitions predict interventions and expose missing structure in actual learned spaces; another successful coordinate alignment would not by itself answer that question.

**Current mathematical position:** S14 separates semantic continuation from internal clocks and identifies source information needed after an edit. S8.1 shows exactly when a mean-only state can support another expected transition; conditional choice can need more. S8.2's independently audited finite example shows that retaining skill ingredients need not retain their achieved composition. Existing representation-learning and successor-feature results offer constructive contracts, with explicit task-family, evaluation and coverage assumptions. These are analytical constraints and external positive precedents, not discovered laws or demonstrated holes in a learned space. S48 adds the diagnostic distinction

between a transported vector and a complete read/write operation; S49 makes later-request use depend on a prepared consumer, not the embedding label. Current routing is below.

## Empirical frontier and intended uses

The general problem map remains a foundation, while renewed reviews supersede S36's compatibility-first allocation. S38 continues strategy after the explicit flexible-approach restart. Scientific evidence-finding remains a possible application. One bounded causal-teaching feasibility preflight was justified, but two execution attempts failed before inference. The downloader bug and owned metadata are corrected; no third run occurs in this allocation. Those failed attempts establish no competence, intervention or cumulative result; S58 later establishes its separate modest teaching result.

| Remaining uncertainty | Evidence that would change the investment |
|---|---|
| Useful contribution | On fresh meaningful joint requests, a contributor performs its assigned role through the receiving interface. Compare omission, the cheapest adequate direct route and legitimate receiver learning; donor-alone superiority is unnecessary. If component competence is weak, composition remains untested. |
| Retained interpretation | A later addition reuses identified evidence/interpretation and keeps established uses adequate, with any repair charged. Compare actual deployed behavior, not just the original baseline. Fixed consumer reuse is useful even without learning across admissions. |
| Consequential effort | Determine whether the intended quality benefit justifies total acquisition, repair, storage and recurring work relative to competent alternatives. Require lower cost only when savings are the claim. |

A useful quality gain can justify additional cost. Cost superiority and progressively cheaper admissions are not universal requirements for cumulative growth.

**Capability grafting and a chimera.** The useful endpoint is a joint behavior such as using specialist evidence in a competent language/multimodal response while preserving prior uses. A map must identify a callable or transportable computation, its inputs and the consumer that can use it. Known stitching and teaching precedents justify investigating this route; they do not establish isolated capability regions, arbitrary donor compatibility, or training-free assimilation. Runtime composition, partial shared computation and donor withdrawal remain distinct investments.

**Reasoning through encoders.** The operative object is a competent observation, comparison, update or candidate judgment, plus a procedure that can use it repeatedly. A decoder is one possible consumer, not an automatic explanation of where reasoning or newly learned knowledge resides. Existing structured readouts and direct use of available evidence are serious alternatives. The selected protein continuation panel had weak first proposals and cannot rule out competent encoder-supported reasoning. The deferred image proposal also leaves participation unmeasured.

**A space that grows across releases.** A persistent system may retain multiple ports, enlarge its representation, or migrate to compatible new providers. It need not place everything into one fixed vector or execute every retained model on each query. Saved embeddings cover their encoded inputs; fresh questions need appropriate callable access or a separately learned export. A retired model's token table does

not preserve its contextual computation. Replacement may preserve a useful interface without adding a capability; a new useful distinction or operation is growth.

**Efficiency applications, including verbosity.** An internal intervention is useful when quality and completion remain adequate and total work falls. Direct prompting, decoding and budget remedies must be measured before attributing savings to latent control. Shorter outputs alone do not establish better reasoning or acquisition. No verbosity experiment or earlier decoding line is reopened by this application.

**Current priority.** Useful contribution has explanatory priority: cheaper admission of an unhelpful contributor is not the desired outcome. That is not a compulsory output-only gate or another preliminary diagnostics program. Choose evidence because its possible outcomes change a concrete acquisition decision in an intended use. S34 is deferred precisely because a narrow measurable participation effect did not yet justify its acquisition and judging cost. Neither a cheap lambda experiment nor another paper catalog fixes that missing value. The next substantive empirical investment must name the use, existing competent resources, permitted new teaching, retained object and rival method together; this map alone queues no construction.

## Philosophy and direction

The enduring philosophy is to take latent space as a world. What would a denizen need to invent to navigate it: identity, moves, effort, maps and laws? Discover mathematical structure through the world's behavior and use it to understand, predict and operate on learned representations. Native means coordinate-independent and effective for the medium; existing mathematics is welcome. This philosophy is broader than any application or current experiment.

The current direction grounds that philosophy in **cumulative capability acquisition**: a persistent representational system that integrates knowledge and computation from successive pretrained models, combines contributions and retains established capabilities as it grows. Failure of this direction would narrow an approach, not settle the larger native-mathematics program.

**So what:** let each new model contribute to a system that keeps what it has already learned and can use old and new capabilities together.

## Exploration areas

1. **Capability mapping and grafting.** Identify causally useful computations and their required interfaces; explore combining language, domain and multimodal capabilities. Capabilities may be distributed rather than located in isolated regions. Behavioral control, such as reducing unnecessary verbosity, is relevant when quality is preserved and total cost is measured.
2. **Reasoning over encoder representations.** Investigate reusable updates, relational composition and intermediate state over pretrained encoders. Distinguish knowledge recoverable by a probe from knowledge usable in a computation. Attribute learning to encoder, interface, reasoner and reader separately rather than crediting everything to the pretrained encoder.
3. **Growth across model generations.** Add encoders and representation-producing

interfaces from decoder-only models, with diffusion and multimodal donors as prospective extensions. New donors should contribute without requiring every existing component to be trained again from scratch. The persistent system may introduce new state or operations; one fixed vector space is not assumed.

Training-free capability grafting is an ambition, not a premise. Small learned interfaces may be valuable; their training and resource requirements must be reported. No proprietary model access or future release policy is assumed.

## Working vocabulary

| Term | Proposed meaning |
|---|---|
| Persistent system S | Representations, permitted operations, readers and retained capabilities before acquisition |
| Donor D | A pretrained model with declared access to weights, hidden states, embeddings, outputs or an API |
| Acquisition I(S,D) | A procedure producing S', including adapters, new state, changed weights and donor dependencies |
| Capability | Performance on an independently specified task distribution with valid behavioral endpoints |
| Connected growth | S' gains usable capability while retaining donor runtime access |
| Assimilated growth | Acquired capability survives removal of the donor and its runtime services |
| Composition | Success on held-out tasks requiring both prior A and acquired B, beyond separate success on each |

For assimilation, declare any donor-derived data or caches that remain and test generalization beyond them. Donor removal alone does not establish transfer of a reusable computation. More vectors, parameters or donors do not themselves establish capability growth. Representation alignment does not automatically transport the operations that produced those representations.

## What an embedding release would mean

A token embedding table is not a language model's contextual computation. Saved activations cover particular inputs. A backbone used as an encoder still incurs its storage and forward-pass cost. A smaller distilled encoder requires training and evaluation of retained properties. A provider could expose or release such resources, but no specific retired model is promised or required.

Technical starting points: [hidden-state access](https://huggingface.co/docs/transformers/main_classes/output) and [LLM2Vec](https://arxiv.org/abs/2404.05961). These support access and adaptation mechanisms, not cumulative reasoning or lossless knowledge extraction.

## Mathematical obligations

| Obligation | What the language should describe or predict |
|---|---|
| Correspondence | Which distinctions have the same operational meaning across interfaces |
| Preservation | Which useful relationships and operations survive translation or grafting |
| Extension | How to introduce previously unavailable distinctions and operations |
| Composition | When acquired and existing operations can be used together |
| Retention | What established behavior survives later acquisitions |

| | |
|---|---|
| Cost | Acquisition, storage and recurring computation required for each contribution |

The strategy notebook develops acquisition-preserving response relations, distinguishing correspondence, operation preservation and useful behavior. S1/S5 give counterexamples where observed agreement fails to preserve later behavior. S14/S15 now ask which usable port can transmit donor improvement and extend its distinctions. These are conditional analytical proposals, not a demonstrated interface. The governing order remains math first, intuition second, compute third.

## Candidate evidence branches

1. Establish each component's competence in its assigned role and a useful conditional donor contribution; standalone superiority on the whole task is unnecessary. Avoid a joint-task ceiling that hides any possible contribution.
2. Integrate one frozen donor under a declared budget; measure held-out B acquisition and A retention with proximal causal controls.
3. Test held-out tasks requiring A and B together. Removal or replacement controls must distinguish joint use from one contributor solving the task alone.
4. Branch by deployment: retain, selectively call, cache, distill, or remove the donor. Removal tests assimilation; it is not a required graduation from useful connected growth.
5. Introduce further donors and retest retention, acquisition-order effects and cross-donor composition. One integration does not establish cumulative growth; two integrations do not establish an indefinitely extensible system.

Compare against the cheapest direct remedy and relevant budget-matched controls: base alone, donor alone, simple routing or text-mediated combination, retrieval over the same donor-derived data, and learning from the same acquisition examples without informative donor representations. Include shuffled or mismatched donors where appropriate. Freeze applicable controls, splits, tolerances and stop rules before running; this list is not a finalized protocol or a demand for every arm.

Account separately for reused donor pretraining, acquisition data and compute, trainable parameters, resident storage, donor calls, inference computation, latency and quality. Include prefill and hidden computation even when no text is generated. Freezing a donor or shortening output does not establish efficiency.

## Relationship to existing work

Future-response identity and continuation refinement offer candidate semantics for correspondence and preservation. Selective-write laws and invariant-relation bounds are conditional retention tools. Causal intervention results distinguish decodability from usable computation. Additive, presentation, competence and execution-mode controls constrain how the next artifacts should be tested.

This project's results establish no cross-model grafting, encoder reasoning system, cumulative acquisition, donor-independent assimilation or cost advantage. Historical failed, invalid and incomplete lines retain their recorded status.

See [STATE](../STATE.md), [axioms](AXIOMS.md),
[continuation refinement](CONTINUATION_REFINEMENT.md),
[breakpoints](BREAKPOINT_REGISTRY.md) and [experiments](../experiments/EXPERIMENTS.md).

## Next-work boundary

**Paused checkpoint, through S65:** on user-authorized restart, strategy/discovery for useful successive acquisition and composition. S58 completed a bounded species-teaching precursor: correct hard pseudo-labels improve a frozen-feature recipient head after donor removal; richer soft targets offer no advantage under this recipe. Preserve that baseline and move beyond this nearly saturated panel. A donor may add information, make useful computation accessible, or justify its cost through better quality. Connected use and ordinary teaching remain valid; donor removal is the selected resource-motivated assimilation branch, not a universal mission gate.

S59 declines a hierarchical classifier comparison without a material admission benefit. S60–S61 supply representation-teaching and operational-coverage precedents; their bounded source inquiry is closed. S62 completed the bounded comparison of retained features versus terminal outputs for within-species attribute questions. It supplies no persuasive reason to prefer specialist internal features over full logits or the existing recipient features under the fixed reader budget. The panel is closed; annotation visibility also limits physical-color claims. Next identify a useful acquisition beyond what the recipient and matched teaching already provide, independently of this panel's errors. No readout-tuning sequence, large reproduction or species-task extension is queued.

S63 supplies an external temporal-service precedent: contributed features support object association while memory and a trained decoder maintain identity and extent. The remaining acquisition comparison is against separately retained contributors with the same competent temporal consumer. Its bounded source read is closed; no unavailable-endpoint search or local tracking reproduction is selected.

S64 declines temporal-state migration before a useful upgrade is bound. A bounded source comparison separates added-feature segmentation gains from recovery-specific evidence, and identifies memory/search using existing weights as a direct remedy. Retrospective trajectory selection and immediate decisions need different timing contracts. Close this source selection without a local tracking reproduction.

S65 completed the supplied-revision consumer probe: all 18 responses terminate, but all three capital prerequisites return country names; zero cases qualify for competent-composition interpretation. The first failed custody attempt and completed retry are separately retained. After the user resumes, the reviewed candidate is only three natural direct capital questions on the same countries, without supplied answers. It is a practical wrapper diagnostic, not a new donor experiment or a queued run. Keep the cloze result closed and its interpretation unchanged.

The next empirical decision must identify what an established system does, what a new donor contributes, and an intended use whose result changes the investment. Allow recipient learning and small CPU preparation, charge both, and give direct comparators the same legitimate prior preparation. Do not require a released packet

or demonstrated superiority before investigating a plausible bounded hypothesis.

An unavailable artifact is a resource limit, not a scientific negative.

| Existing question or route | Completed work to read before proposing more | Remaining decision |
|---|---|---|
| Shared frozen predictor with separate acquired ports | S42 conditional prefix/gradient reuse and implementation boundary; S52 isolation and later-use objectives | Useful second-donor teaching at charged effort versus separate students allowed to share features. Another cache proof does not supply acquisition evidence. |
| Prepared contribution used in a joint computation | S29 typed operation reuse; S40 separate preparation/joint-use source; S50–S51 semantic/spatial/depth trace | Demonstrated useful contribution and retained achieved uses. The existing depth example has a sufficient direct interface; do not rediscover a missing handoff there. |
| Consequence retained for later requests | S49 consumer dependency; S52 marginal versus shared-analysis contract; S53 one-query attribution comparison | A competent, affordable consumer of the intended consequence. Credit decode-once structured records. One late query does not establish cross-request consistency. |
| Changing an accumulated system | S13 admission order; S32 corrections; S50 replay dependency; S54 order/retention source | Useful new behavior and effects on established uses under actual admission histories. Final order robustness, admission-relative BWT and joint retention are different. |
| Contributed policy revision | S55 global concept-weight edits versus local attribute corrections | Useful held-out edits and collateral effects through a competent consumer. The reviewed source is not a trained local endpoint or a new-specialist acquisition result. |
| Mapped feature used as an operation | S56 tool-feature scorer and live-input/write-port trace | Requested-action evidence through an actual recipient write port; feature localization and offered-name emission do not establish executable acquisition. |

**Closed or deferred execution boundaries remain binding.** S37 has two failed attempts and no third run queued. S43's response slice and S47's direct-remedy panel are closed. S34 is deferred; only material evidence arising through other work can justify reconsideration, not a new bank hunt or proposal loop. S40's joint-run metadata search, S49's small-checkpoint check, S51's exact combined-model endpoint, S53's reaction-model access check and S55's concept-consumer lookup are closed for this allocation. Their broader scientific questions remain open. No unavailable real CLI reviewer needs repair; available independent reviews have explicit provenance.

Local accounting is nine probe blocks, 666 recorded calls (15 earlier batched, 540 single-image and 111 S65 retry calls), plus 1–16 unrecorded calls from S65's failed attempt: total 667–682. There are 2400 head optimization steps and 45 ridge preparations; 1710 apparatus lines and zero reusable artifact-bearing lines, zero building rounds. No GPU. A zero-denominator ratio is undefined; do not construct something merely to improve it. Source/manual calculations are not model runs. Detailed decisions, evidence and historical routing remain in S0–S65 and the ledger.

## Conditional route choices

These are research branches, not a construction plan or a required ladder. The same task and access contract must control comparisons; otherwise the route with more information or supervision can appear to have a better latent language.

| Route | Evidence that would make it appropriate | What must be worked out |
|---|---|---|

| | | |
|---|---|---|
| Typed donor ports with an explicit executor | Existing callable outputs supply the needed distinctions and a competent executor can use them | Scope, units, uncertainty, arbitration and total donor-call cost; direct use is a serious baseline and can be a useful endpoint |
| Explicit knowledge import with a reusable editor | Donor-derived facts or corrected targets supply the desired new information | Source reliability, dependent consequences, retention, routing and comparison with keeping those facts in context or retrieval; this need not transfer the donor's computation |
| Frozen donors with learned receiving interfaces | A useful donor distinction is supported, but current receiver access loses it; declared learning can plausibly repair or extend the interface | Attribute learning to donor, adapter and receiver separately; show preservation under a new use rather than only the fitted task |
| Persistent shared state or an atlas of ports | Joint tasks need retained intermediate distinctions and reusable operations that the cheaper interface cannot economically support | Identify legal writes, old-operation preservation, new distinctions, coupling evidence and growth cost; a common coordinate chart alone is insufficient |
| Compact donor-independent export | Deployment requires removal of donor runtime, with an explicit future question family and acceptable loss | Compare caches, distillation and reusable exports; count all retained donor-derived information and validate questions beyond stored answers |
| Co-designed next latent space | Repeated, localized, task-relevant interface failures identify a missing structure that simpler remedies do not restore | Build only the needed distinction or operation and test its causal contribution; failure of one adapter or diagnostic does not prove an architectural hole |

**Learning accounting:** list which component receives paired examples, task labels, teacher answers, inference-time evidence and updates. Generic paired alignment data can legitimately teach an interface; task-answer supervision can legitimately teach capability. Neither should be silently attributed to knowledge already exposed by the frozen donor. A randomized-donor or uninformed-feature control is useful when it tests that attribution, with input, labels, trainable capacity and budget matched. It is not a universal control that every experiment must run regardless of its claim.

**Near-term strategy deliverable:** one task-specific contract with a competent direct route, a named useful missing distinction, an obtainable donor port, declared acquisition information, and one result that would change the chosen route. The recent probes do not yet supply that contract. More diagnostics are not a substitute for it. No route above is licensed to claim a new kind of reasoning merely because it omits autoregressive text output.

**Selection correction after periodic review:** a cheap baseline is a comparator, not a universal prerequisite for investigating a richer port. Failure of an output average cannot exclude a useful distinction the outputs discard. Require competence on assigned component roles; standalone superiority is needed only for a claimed better replacement. Measure conditional contribution on the joint task. Record what the receiver already does and what acquisition newly teaches it. The reviewer independently identified this narrowing error; a separate two-round design dialogue reached the same correction. Further generic diagnostics and architecture surveys now have diminishing returns; the named task controls work.

## Strategy notebook

Status: active autonomous strategy/discovery, authorized 2026-09-13. No system building. This section is a working problem map, with propositions explicitly

labeled as attempts until checked. Small CPU experiments may discriminate hypotheses; no large-model acquisition or massive compute is planned.

### S0. Initial decomposition and questions

The contribution from a donor could be (a) facts or associations, (b) a reusable operation, (c) a representation that makes existing operations cheaper or easier, or (d) ongoing access to donor computation. These are candidate categories, not a claim of exhaustiveness or mutual exclusion. Each needs separate endpoints.

Questions to resolve first:

- What distinguishes knowledge transfer from learning the same answers from donor-produced examples, and when is that distinction useful rather than cosmetic?
- Which interfaces expose executable operations, rather than snapshots?
- Can two donor interfaces be aligned observationally while disagreeing under interventions or new compositions? What extra evidence resolves the ambiguity?
- Does a persistent system need a common space, a family of translated spaces, or an expandable typed state? Which observation would favor one?
- What is the minimum useful donor-independent artifact, and what must it retain?
- What incremental advantage should survive a router, text channel, retrieval, direct distillation and equally funded new learning?
- Which parts of the shape can be resolved analytically or from existing data before any model is loaded?

Initial strategy expectation: useful representation similarity will often be insufficient for operation transfer. Counterexamples should identify exactly which missing assumption matters; they do not imply real models cannot transfer. A second expectation is that factual acquisition and computational acquisition need different controls. We will revise either expectation if the evidence does.

### S1. Access before architecture (initial approach review, 2026-09-13)

Review recorded on audit board e5a4e16f, entries e954–e956. The mission remains fixed. The correction is to separate contribution (information, operation, accessibility, cheaper realization) from deployment (retained, called, cached, distilled, removed). Donor removal is one research branch. Knowledge learned from examples remains useful acquisition if its generalization and costs justify it; hidden-state transfer is not inherently a higher form of learning.

**So what:** a future system could keep learning useful things from new models without discarding what it already knows or rebuilding everything each time.

**Definition attempt S1.1 — acquisition experiment.** Specify a tuple `(R, D, E, U, V_old, V_new, V_joint, B)`: recipient R; donor D; permitted export interface E; acquisition procedure U; old, new and joint task/continuation families V; and resource budget B. E includes what can be queried, on which inputs, with which interventions, how often, and whether access survives acquisition. The retained artifact is `R' = U(R, transcript(E,D))`; this notation includes a connected system whose transcript grants continuing donor access. For a donor-independent artifact, future D calls are explicitly absent.

This separates three questions: does E expose the required distinction; can U

make it usable within B; and does the resulting behavior remain useful after later acquisitions? Failure of the second is not evidence against the first.

**Proposition attempt S1.2 — access ambiguity.** Let two possible donors D0 and D1 induce the same distribution of every transcript obtainable under the declared acquisition protocol. Suppose the desired donor-relative binary answer on one held-out query is 0 for D0 and 1 for D1. A donor-independent acquisition algorithm with no other distinguishing information cannot guarantee success above 1/2 on both donors on that query. Proof: its output law is the same in both worlds. If it answers 1 with probability p, the two success probabilities are 1-p and p, whose minimum is at most 1/2. With equally likely worlds, their mean is 1/2. Abstention cannot increase unconditional correctness. This elementary identifiability argument is not a new mathematical result or a claim that actual models form such a pair.

**Concrete operational witness.** Both donors expose states s0 and s1 with the same coordinates and current readout 0. A third state s2 has readout 1. All observed calibration actions loop at s0. An unqueried action a at s1 loops to s1 in D0 but moves to s2 in D1. Paired static embeddings can match perfectly, including s2, while the answer after a differs. Querying a at s1 resolves this particular ambiguity. Passive alignment alone does not. This is a logical counterexample, not a toy-world capability experiment.

The escape is a justified restriction or additional access: covered transitions, a known operation family, a restricted reachable domain, or tested regularity. Finite observations need not be hopeless: they can identify a finite known family. Conversely, more adapter parameters do not supply missing information. For an adaptive protocol the premise concerns its whole transcript law, not merely the initial calibration set.

**Question generated:** what is the weakest task-relative equivalence that permits joint use without forcing the recipient to imitate the donor's internal algorithm? State/action conjugacy would be sufficient in some settings but is likely unnecessarily strong for acquisition.

### S2. Growing the questions, not just the coordinates

**Definition attempt S2.1 — conservative interface extension.** An old interface I has legal queries/actions and responses. An extended interface I' includes a meaning-preserving embedding of old queries/actions and admits new ones. On a declared distribution or reachable domain, old response laws change by at most epsilon under the embedded old interactions. New tasks are evaluated separately. For generative interfaces the response includes termination/abstention and the declared output interpretation. No universal numerical epsilon is assumed.

Old observational equality need not survive the new questions: two states that previously answered every available question alike can become distinguishable. Therefore extending a fixed old quotient can require splitting a class. Adding coordinates without adding usable queries need not add an accessible capability. Conversely, an expanded query language may expose distinctions already encoded.

Neither case alone establishes new information acquired from a donor.

**Three independent retention obligations:** (i) an old path remains executable; (ii) that path still behaves adequately; (iii) the deployed selector still uses it appropriately. Freezing old weights addresses only part of these obligations. Adding a router can degrade deployed performance with every old module intact.

**Growth bookkeeping, not a lower bound on learning complexity.** N directed donor-to-donor adapters require at most N(N-1) pair interfaces if all pairs are implemented separately. A fixed hub needs at most 2N directed adapters, but this does not guarantee constant integration effort or semantic compatibility. A hub update can invalidate earlier maps; a fixed hub may fail to express a genuinely new distinction. Candidate alternatives include stable typed ports, a versioned hub with old semantics preserved, and an atlas of partially overlapping spaces. No choice has been made. The next discriminant is which obligations change when one donor with a new distinction arrives, not which diagram looks simplest.

**Working target S2.2 — reusable acquisition procedure.** Let a declared procedure `A(S, D, E, B)` produce an updated persistent system from its current state S, donor D, permitted integration evidence E and budget B. A may train an adapter, adapt the receiver, allocate new state or register typed operations. Reusing A does not mean freezing its learned outputs. Its recipe, evidence permissions and budget rule remain fixed across the evaluated donor sequence. Inventing a new manual rule or training recipe later is a revision of A, not evidence that the old procedure handled that donor. Revisions remain legitimate research progress. Known donors can support exploratory design; evidence of procedure generalization needs donors or acquisition cases not used to invent or select that recipe. Available metadata and calibration examples remain declared inputs to A.

After each integration, evaluate fresh inputs and new combinations of declared operations without further task-specific fitting. Continuing donor calls are allowed and charged. Adding a new operation type is a different challenge from adding another provider of an existing type; report which occurred. A first short sequence could use three acquisitions to expose repeated integration, not because three proves scalability. Old behavior, joint usefulness and integration burden must be followed across the sequence. Receiver training during acquisition remains permitted. Assimilation additionally requires fresh-input use after donor withdrawal; keeping answers for previously seen inputs is not that capability.

This selects the intended reusable object, not a task or a queued run. S24 later closed its scoped example through a sufficient typed executor. A stable typed acquisition procedure may satisfy this target; a growing collection of bespoke integrations may be useful while leaving procedure reuse unestablished. The native question is whether a common operational language makes the next addition less costly without losing distinctions or invalidating established uses.

**Worked allocation after two fresh direction rounds.** Consider a declared same-operation replacement: given a graph and source, return minimum unweighted hop distances with agreed node correspondence and unreachable convention. This is an analytical specialization, not an operation/second-provider replacement

verified in TransNAR. Equal tensor shapes would not identify this semantic contract.

Fresh uses are new graphs/sources and declared downstream uses; no implementation or clean interpretation module is assumed.

| Recurring obligation | Frozen receiver, new adapter | Receiver adaptation under reusable recipe | Direct structured use |
|---|---|---|---|
| Teaching | Charge task labels and paired donor states; state pairs are teacher supervision and require both providers' calls | Charge new targets, teacher calls, replay and selection queries | No answer supervision intrinsically needed **if** a ready adequate decoded port exists; otherwise charge decoder learning |
| Learning work | Charge all adapter optimization, including backpropagation through a frozen receiver; the adapter can relearn task computation | Charge receiver/adapter updates; reused initialization is a potential saving, not free learning | Charge conversion, calibration and any learned formatting/consumption |
| Preservation | Recheck selection, indexing, normalization and old/joint uses; charge repairs or retained paths | Same obligations plus update interference and replay | Isolation can preserve old paths, but shared routing/joint uses still require checks |
| Continuing use | Donor, transfer, adapter/fusion and receiver calls | Donor and adapted hybrid calls | Donor, decoding and downstream computation |

Preserved receiving weights establish parameter reuse, not reuse of interpretation. The first dialogue's stronger wording was withdrawn in the second. All adapter learning counts; paired hidden states are not supervision-free. Separately report initial integration investment and reused donor pretraining, charging new donor training when it occurs. A route saves acquisition effort if, on provider additions or replacements not used to design its recipe, it reaches matched fresh-use quality and old/joint retention with less repeated teaching, optimization or repair. Keep resource dimensions separate absent a defensible workload tradeoff; lower teaching cost with higher recurring inference is a qualified result. This supports practical acquisition savings without needing a mechanistic transplant claim first.

A new operation may require new downstream learning. New facts under the old operation, such as added edges, instead require access/import and stale-answer invalidation; learning the algorithm again is not intrinsically required. Neither case is identified by a new model name or a new embedding dimension. The choice from this block is to grant freezing no privileged status and retain direct use as the reference route. Missing evidence: a semantically matched second provider, a usable interface for each route, and comparative acquisition/retention receipts. The existing positive hybrid does not supply those observations. This allocation block is closed; current routing lives in the Next-work boundary.

### S2.3. A concrete retention obligation when the port grows

**Conditional calculation, not an empirical finding.** Freezing receiving weights does not preserve old behavior if adding a donor changes the inputs over which it normalizes. For a fixed attention query, let the old keys have softmax partition sum Z and weighted value average y. Let new keys have sum Z_new and average y_new. Concatenating them yields exactly

`y_extended = (Z*y + Z_new*y_new)/(Z + Z_new)`.

Even new **zero values** change this output to `Z*y/(Z+Z_new)` when their keys receive positive weight. Uniformly duplicate the entire normalization pool, holding keys/scores/values

fixed, and y stays unchanged. Duplicating just one donor stream changes its mass when other streams share that pool; positional changes also invalidate the fixed-key premise. Thus a generic “duplicate-donor” control is underspecified: what is duplicated, and what mass or prior should that represent? This elementary softmax calculation is ordinary scaffolding, not a new law of learned latent space or a statement that every hybrid uses this design. A downstream decision may remain unchanged despite the local difference.

The acquisition choice it changes is concrete: preserve the old input path, exclude inactive donor keys from its normalization, use an explicitly separate branch, or learn and validate a new selection policy. Zero-gating a separate new branch can preserve the old path at initialization under its stated wiring; it does not guarantee retention after training or on newly combined uses. None of these caller-supplied safeguards establishes discovered latent structure. If integration claims old behavior survives because weights are frozen, check routing, normalization and visible donor multiplicity as well as parameter hashes. Matched constant/irrelevant ports belong in the corresponding growth comparison. The unresolved learned question is which uses can share a receiving interface without extra calibration or harmful changes, and whether an operational map predicts that economically before a new integration is trained. No run selected.

### S2.4. Decision question before further source inspection

**Proposition attempt, unestablished:** a task-conditioned description of donor behavior can reduce the total cost of selecting and integrating a useful donor, relative to directly trying candidate integrations under the same recipe. The action served is donor selection before costly adaptation, not predicting responses for their own sake. The description and its labels/queries/computation must be charged. It cannot be judged by reusing the donor/task cases that designed it.

A predictor of final task accuracy after one fixed adaptation budget is not yet a predictor of supervision or computation needed to reach a quality/retention threshold. Both can inform acquisition, but they change different choices. Likewise model-level transfer potential does not identify a causal capability module or show that old/joint uses survive. Before inventing a metric, inspect existing transferability estimation for exactly these targets and data permissions. This selects a bounded primary-source question, not a model or computation run.

**Source check, 2026-09-14.** You et al., *LogME*, ICML 2021, [official paper](https://proceedings.mlr.press/v139/you21b/you21b.pdf), §§3–6, estimate transfer suitability from fixed pretrained features and labeled target examples. A Bayesian linear readout marginalizes weights and optimizes evidence hyperparameters. Experiments compare scores with downstream performance; the vision fine-tuning comparison searches learning rate and weight decay, whereas language comparisons use published fine-tuning results. Scoring avoids backbone fine-tuning, but requires feature extraction and labels. The timing comparison concerns assessing candidates against fine-tuning with hyperparameter search, not eliminating adaptation of the selected model. The authors explicitly identify static pre-adaptation features as a limitation. This is useful selection

evidence, not a measurement of integration time to a retention-constrained target.

Achille et al., *Task2Vec*, ICCV 2019,

[main paper](https://openaccess.thecvf.com/content_ICCV_2019/papers/Achille_Task2Vec_Task_Embedding_for_Meta-Learning_ICCV_2019_paper.pdf),

§§3–4.2, and [supplement](https://openaccess.thecvf.com/content_ICCV_2019/supplemental/Achille_Task2Vec_Task_Embedding_ICCV_2019_supplemental.pdf),

§§3–4.3, describe labeled tasks through a shared pretrained probe: fit a classifier and estimate a diagonal Fisher description averaged by convolutional filter. The principal selection endpoint is expert classification after training a new linear head. Task distances guide selection; MODEL2VEC additionally learns model offsets from measured performance on other tasks. Its leave-one-task-out protocol withholds the target task's performance supervision, not an entire expert family. Probe fitting, labels and upstream library/performance construction count as resources. The main/supplement Mixed task counts differ, so no count-based claim is imported here. These results support selecting useful experts, not cumulative integration or retention; the description depends on the probe and task, rather than being an intrinsic inventory of a donor's capabilities.

**Our inference and decision.** Both precedents make model selection a credible use of a representation description. Neither inspected protocol measures the added contribution to an already capable receiver under repeated acquisition. High standalone suitability can be redundant with what that receiver already does. Conversely a donor poor at the whole task can supply a missing operation. S19's receiver-conditioned probing addresses accessible predictive information under a declared readout family; it does not by itself estimate the learning, retention repair or continuing calls needed by a different integration recipe. Subtracting standalone scores does not establish that missing comparison.

The prospective map must therefore be evaluated against an action: which **donor and permitted integration recipe** to try, at what budget, for this receiver and fresh-use obligation. A descriptor can be useful without being native mathematics; that stronger claim would require stable operational relations across presentations and interventions. Two subsequent fresh strategy rounds close predictor design as the immediate inquiry. Direct trials can leave reusable trained parameters, examples and observations; compare incremental effort after crediting that progress, not gross screening expense alone. A short unsuccessful trial is not proof that longer adaptation would fail. Nor must two operational routes exist before a useful acquisition obligation can be studied. S14 works one such obligation on paper; no new metric or empirical run follows.

### S3. Primary-source map: what can already be reused?

Read on 2026-09-13. These are externally reported results, not project replications. Rows distinguish demonstrated mechanism from our inference about its relevance. A paper's use of "latent" does not establish the project's full acquisition contract. Section/table locators make the reading reproducible.

| Primary source | Mechanism and evidence read | Strategic implication / limit |
|---|---|---|

| | | |
|---|---|---|
| Moschella et al., *Relative representations enable zero-shot latent space communication*, 2022/ICLR 2023, [paper](https://arxiv.org/html/2209.15430), §§3,5,6 | Coordinates are similarities to corresponding anchors. Exact cosine invariance covers angle-preserving transformations, not arbitrary shifts. Frozen pretrained encoders can feed classifiers trained on relative representations; reconstruction experiments train relative interfaces end to end. Table 6 shows substantial variation across encoder/decoder pairs. | Anchor-relative interfaces are a concrete reuse baseline. "Zero-shot" stitching does not mean the receiving readout never learned this interface. Arbitrary acquired operations and cumulative retention remain separate questions. |
| Rusu et al., *Progressive Neural Networks*, 2016, [paper](https://arxiv.org/html/1606.04671), §§2,5 and Appendix B | Add a new trainable column with lateral access to frozen old columns. Sequential reinforcement-learning experiments examine transfer. The basic construction grows hidden units linearly and parameters quadratically with columns. | Connected growth with frozen earlier computation has a concrete precedent. Its bookkeeping and old-task selection requirements belong in our baselines; it does not assimilate arbitrary independently trained donors for free. |
| BehnamGhader et al., *LLM2Vec*, 2024, [paper](https://arxiv.org/html/2404.05961), method and Appendix A | Decoder backbones become embedding models through bidirectional attention, masked next-token adaptation and contrastive learning. The limitations discuss model and index size. | Supports decoder-to-encoder adaptation as a candidate export. The retained backbone is not a tiny standalone embedding table, and embedding quality does not establish preservation of donor reasoning. |
| LCM team et al., *Large Concept Models: Language Modeling in a Sentence Representation Space*, December 2024, [paper](https://arxiv.org/html/2412.08821), §§2.4,3,6 | Learn a next-sentence model over SONAR representations. Initial 1.6B models use about 1.3T tokens; the 7B version about 2.7T. Limitations include fragile numbers/code, local geometry versus global prediction, and encoder mismatch. | Reasoning/generation over an encoder space is a real research route, but this precedent trains substantial new computation. It does not establish that a cheap reasoner is already recoverable from embeddings. Encoder, transition and decoder costs all matter. |
| Liu et al., *The Vision Wormhole*, February 2026, version 2 May 2026, [paper](https://arxiv.org/html/2602.15382), Appendices C,D | Train per-model codecs through a visual-token interface using text teacher behavior; align universal tokens with paired anchors. Frozen backbones still execute read/think/write cycles. Appendix D presents a shared-semantics affine model as an explanatory hypothesis; scope depends on compatible visual interfaces. | A hub with learned ports is relevant to connected growth. Interface count is not proof of semantic extensibility; the paper's hypothesis is not a general theorem about arbitrary donors. |
| Chen et al., *See What I See, Know What I Think*, June 2026, [paper](https://arxiv.org/html/2606.13594), §§4,5 | Cache reconstruction followed by receiver-style supervised reasoning trains a communication module. Six directions among three sizes of one model family; context-aware and context-unaware evaluation. Inference FLOPs use a parameters-per-token estimator. | Dense context transfer and auxiliary steering are distinct uses. This is trained inter-model communication with donor runtime, not demonstrated permanent acquisition of its parametric knowledge. Broader architectural and repeated-acquisition claims need additional evidence. |
| Liu et al., *Dual-Cache Latent Space Communication between Heterogeneous Language Models*, August 2026, [paper](https://arxiv.org/html/2608.20617), §§3–5 and Tables 5,22–24 | Frozen sharer/receiver models get partitioned evidence; learned cache pooling, joint memory and residual injection train on answer cross-entropy. Three families, nine ordered pairs, five tasks; paper reports one run on an A100 and a 64-token receiver cap. Text baseline generates a message. | Particularly close to complementary-context composition. A direct evidence-forwarding baseline matters because generating a summary is not always the cheapest text channel. Reported wins do not establish termination gates, repeated acquisition or donor removal. We do not import their efficiency headline as a project claim. |
| Gröger, Wen and Brbić, *Revisiting the Platonic Representation Hypothesis: An Aristotelian View*, February 2026, version 2 June 2026, [paper](https://arxiv.org/html/2602.14486), §§4–7 | Calibrate similarity against sample permutations and calibrate the actual layer-selection aggregate. In tested settings, local neighbor agreement survives better than global spectral/distance agreement. Guarantees require exchangeability; clustered samples need restricted permutations. | Geometric correspondence is an uncertain empirical ingredient. Use matched dimensionality/search nulls when geometry is investigated; even calibrated correspondence does not establish causal transfer. |

**Full-source update, 2026-09-13:** Smith, Mannering and Marcu,

*Functional Alignment Can Mislead: Examining Model Stitching*, ICML 2025,

[official PDF](https://raw.githubusercontent.com/mlresearch/v267/main/assets/smith25a/smith25a.pdf),

§§2,4,5,7 and Appendix A/B.2, is now accessible. Frozen sender prefixes and receiver

suffixes are joined by supervised 1×1 convolution stitches with batch normalization.

Correlated-MNIST train/test cues agree, so accuracy does not identify the cue used. Clustered noise is class-informative: train and test perturb the same random class centres, not independent label-free noise. Changed input tasks and circular label remapping show that stitch training can supply correspondence. Failed stitches remain ambiguous because optimization or competence may fail.

**Our inference:** successful supervised compatibility can be useful acquisition; it does not identify preserved donor computation. Declare what the adapter learns and which donor interventions/compositions should survive. No causal correspondence, cumulative retention or donor-independent acquisition follows from final accuracy. This resolves the earlier abstract-only limitation without turning acquisition into a requirement that adapters learn nothing.

**Synthesis so far (our inference):** available components make connected communication plausible enough to investigate, while pretrained spaces may discard distinctions required for exact downstream tasks. The sharper open problem is acquiring *reusable, compatible contributions under bounded new learning*, not merely constructing another shared chart. This is a working research emphasis within the mission, not a claim of novelty or architecture selection.

### S4. Cheap-trick controls arise from the information path

For partitioned-context tasks, a message-producing language model is not the cheapest text baseline. Forward the already available source evidence verbatim (within a matched context budget), retrieve the relevant span, or send a compact structured field. A latent channel winning against generated prose could be avoiding unnecessary generation rather than transferring inaccessible knowledge. This is our proposed control, not a claim that the cited methods fail it.

For donor facts unavailable in the recipient, record where acquisition labels came from. If the correct answers supervise an adapter, an equally funded learner with those answers has received part of the very contribution being attributed to the donor. This does not invalidate supervised transfer; it changes the baseline needed to establish incremental value from internal representations.

For repeated tasks, compare cached answers/retrieval before maintaining a whole donor. For new operations, hold out *uses of the operation* and joint compositions, not just names in a fixed answer table. For cheaper realization, match quality and termination before comparing recurring cost, and include the one-time acquisition bill. For verbosity reduction, direct decoding/prompting controls come before a supposed verbosity subspace.

**Proposition attempt S4.1 — break-even accounting.** If acquisition adds cost A and changes mean per-query cost from c0 to c1 at an accepted quality level, then after n queries the net compute saving is `n(c0-c1)-A`. For c1<c0 it turns positive only above `A/(c0-c1)` queries. If c1>=c0 there is no compute break-even under this stationary model. This accounting does not value higher quality, latency constraints or privacy; report those separately. For donor-selective runtime, c1 must include call probability and donor prefill/computation. Storage

and integration repair across versions need their own totals.

**Existing-data check:** the current `experiments/results` tree contains no retained `.npz/.npy/.pt/.safetensors/.parquet` arrays/checkpoints in the checked extensions (including ignored files). Several representation directories retain manifests or summary JSON rather than paired activations. Large donor checkpoints and old scorer artifacts exist under `legacy`; they were not loaded. This does not prove no useful numerical data exists inside JSON or elsewhere. Next inspect specific retained response tables only if a new question can be answered; do not repeat an old congruence calculation merely to produce a compute receipt.

### S5. Contextual substitution instead of algorithm imitation

Reviewer dialogue sharpened the S1 question. A recipient may implement the same useful operation through a completely different internal algorithm. Requiring a global bijection or step-for-step donor simulation would exclude valid reuse.

**Definition attempt S5.1 — task-port substitution.** A port specifies accepted inputs, outputs, session/reset semantics and legal interaction histories. Let C be a declared family of downstream contexts: procedures that can call this port, combine its results with other contributors, and produce an observable result. Ports P and Q are epsilon-substitutable relative to C if, for every included context and initial condition, the final response laws differ by at most epsilon in the declared metric. With total variation, every bounded [0,1] output score changes in expectation by at most epsilon. This is a behavioral definition, not an efficiently checkable certificate. A small tested C licenses only that scope.

**Sufficient-condition attempt S5.2.** For contexts making at most k adaptive calls, suppose P and Q have conditional output kernels within epsilon_i in total variation at call i on every common reachable interaction history. Suppose the same context receives no other distinguishing side channel and its own random choices can be shared. Then final-response TV is at most `min(1, sum_i epsilon_i)`. Couple each next port output maximally while histories agree. A union bound controls the first disagreement; if none occurs, all subsequent context computation and the final answer can agree. No correspondence between internal hidden states or algorithms is needed. Kernel coverage is the substantive assumption, not something supplied by a small calibration sample. Timing, errors and termination must be included among responses when contexts can observe them. General continuous spaces require the usual measurable kernel and coupling conditions; the elementary proof here is for finite outputs.

**Why marginal tests fail.** P samples one fair bit per session and returns that same bit on every call. Q samples a new independent fair bit per call. Every single-call marginal is identical. A context asking twice and checking equality returns true with probabilities 1 and 1/2. Once the first response is known, the second-call kernels differ. A snapshot export that loses session identity can therefore pass isolated-query tests and fail composition.

**Why this matters for the denizen:** a usable imported tool must continue to mean the same thing when used again, chained with another tool, or applied after

an intervening action. A static chart cannot specify those obligations alone. The native vocabulary candidates are typed ports, continuation-sensitive identity, admissible contexts and extension laws. Existing mathematical language is welcome; the contribution must be useful structure discovered in real spaces.

### S6. Candidate cached-data eligibility (before numerical fitting)

Read-only metadata inspection found two small legacy latent bundles, each about 55 MB, under `legacy/checkpoints/latent_scorer/`: unsuffixed `gemini_training_merged_latents.pt` and the `_qwen3_4b_1024.pt` variant. Their pickle metadata names different encoder models and stores query/plan latents, scores and metadata. We inspected archive metadata without deserializing tensors. These may permit a tiny cross-model probe, but filenames are not paired-data provenance.

**Expectation before an integrity check:** genuine paired representations should have matching record identities/targets and nonidentical query/plan tensor storage. Identical feature storage would void their use as independent donor views. Different storage plus matching scores is necessary but insufficient: row identity, pooling/projection and source-task leakage still need checking. The simplest confound is duplicated or misaligned records, so inspect archive shapes/metadata/storage hashes first; do not fit a bridge yet. No model loading, training or capability comparison is authorized by mere cache existence.

**Integrity result, 2026-09-13:** both archives describe 13,464 rows, 1,024 dimensions, layer -4 and mean pooling. Feature storage hashes differ; score storage hashes match exactly. Unsuffixed query/plan SHA256: `8871c1cf0c3220d88b0036780b4b80fa41fe28db3162778d5855c478b02a903f`, `1be832e90a61499881e68a75fdab145a2ab4000f9cd96ad5080732b5d56b18d4`. Suffixed query/plan SHA256: `3344f26688c68b00473ff26fc355bc992453df312b01c1d54bf82d2398d27748`, `7d9941cdb6bd05374a9ca1c7810e78ba6bd299dd52ac200cd5c129f52a31857a`. Common scores SHA256: `3c07f300e63211de975b5a57b03064ca693b9a41a61f82fa6e3417848cddecec`. This eliminates exact feature-file duplication, not row misalignment or shared projection confounding. No row identifiers appear in inspected metadata. These are legacy quality-scorer targets, not ground-truth reasoning-capability labels.

**Next integrity question, predeclared:** do repeated query-row partitions agree between bundles? Identical repeat groupings would strengthen, but not establish, row correspondence. Different groupings could reflect batching/precision or misalignment and would require provenance before analysis. Hash exact row bytes; do not interpret equality as a semantic equivalence relation. Inspect only these two roughly 55 MB bundles; no model or fitting. The surviving encoder code (`legacy/src/latent_reasoning/core/encoder.py`, `_init_latent_projection`) initializes dimension reduction by retaining the first coordinates, not a learned universal map. The cache metadata does not pin that implementation revision, so treat this as a provenance concern, not established cache-generation behavior.

**Full bounded integrity probe:**

[`run_acquisition_probe.py`](../experiments/run_acquisition_probe.py),

[result](../experiments/results/acquisition_cache_integrity_v1/result.json).

Initial scan completed in under one second; after schema hardening the final

scan took about 1.23 seconds. No model calls, tensor deserialization or training. Unsuffixed queries: 2,906/13,464 rows wholly nonfinite. Unsuffixed

plans: all 13,464 rows wholly nonfinite and byte-identical. Suffixed queries and

plans are finite, but plans have only 79 distinct rows; 13,386 rows are the all-zero vector.

Among 10,558 mutually finite query rows, exact repeat partitions agree on 9,823

row representatives. Exact partitions are integrity diagnostics, not semantic

identities. Unknown batching/precision and missing IDs prevent a stronger pairing

claim.

**Decision:** do not use these bundles for cross-model plan transfer or

capability attribution. The failure is in the retained export's eligibility;

it does not prove either underlying model lacks useful structure. The finite

query subset might support a narrowly scoped representation exercise after

provenance recovery, but that is lower leverage than the current strategy

questions. No source caches were modified or discarded. Their original creation

failure is not diagnosed here, and historical capability claims are not inferred

from this old scorer material.

**S6 review closeout:** independent audit e1011–e1012 upheld scoped export

ineligibility and independently confirmed NaNs and zero vectors. The runner now

pins the reviewed metadata hashes, shape and byte order. No source repair or

query-subset alignment is selected. Final result and runner hashes are in the

ledger review event.

### S7. Adequacy, substitution and justified correction

The reviewer follow-up (audit board e957–e960) adds a necessary qualification to

S5: there is no unique weakest contract until permitted tests are specified.

Comparing only declared task payoffs is weaker than comparing all output laws.

More fundamentally, acquisition should satisfy the task, not reproduce every

mistake of an imperfect donor. The S1 impossibility claim is deliberately

donor-relative; it does not limit a recipient with a better independent source.

Keep three levels separate:

1. Desired outcome: task-relative adequacy, retention and useful joint use.
2. Possible certificate: conditional port-error bounds on covered histories.
3. Possible implementation: translated representations and preserved operations.

A successful system may satisfy the first through a route other than the third.

A finite test of the second is evidence on its support, not a proof over every

future context. If at most eta probability mass encounters uncovered histories

under a justified reference/coupling analysis, the bound needs an additional eta

term. An empirically small calibration failure rate is not such a guarantee.

**Retention must allow declared correction.** Successive donors can disagree.

If new evidence corrects an old factual answer, exact preservation of that answer

would conflict with the acquisition objective. Before evaluation, separate old competencies whose specifications stay fixed from questions intentionally revised by the acquisition. Measure interference on the former and correction quality on the latter. Do not relabel regressions as corrections after seeing results.

This creates another native requirement: a growing space may need to retain source, scope, uncertainty and revision meaning, not merely blend two numerical representations. Keeping incompatible claims distinguishable can be more useful than forcing them into one average. Whether this metadata must live in a latent state, an explicit interface, or both remains open.

### S8. What "reasoning over an encoder" could mean

The phrase covers substantially different programs. The following is a candidate taxonomy, not a claim that each route is already demonstrated or equally useful.

| Route | What supplies the next reasoning step? | Principal question |
|---|---|---|
| Retrieval over an embedding index | An external reasoner consuming retrieved items | Does retrieval expose the needed evidence, and is the missing capability really retrieval? |
| Specialist readout plus reasoner | A small decoder extracts entities/relations/uncertainty; existing reasoning composes them | Which task-relevant distinctions survive a reusable structured readout? |
| Rich representations injected into a reasoner | An existing backbone plus learned input/interface adaptation | Is the richer channel useful across changing questions beyond equally funded structured extraction? |
| Repeated encoder calls with explicit state | A controller chooses new inputs, masks or updates | Is useful computation reused, or does the controller learn the task from scratch? |
| Learned transitions directly over representations | A newly learned recurrent/transition model | Does donor pretraining reduce the data/compute needed to learn valid transitions? |
| Encoder as verifier/energy signal | Search proposes candidates; encoder-derived score ranks or rejects | Does the score track real task quality under optimization, beyond its training distribution? |

The project history makes the last row especially cautionary: a learned latent score is guidance, not independent quality evidence. Selecting candidates with the same score used to claim improvement does not answer the question.

A static vector export, a callable contextual encoder, and a backbone with legal intervention/readout operations are different resources. A callable encoder can respond to new inputs; a finite index cannot generate missing representations without another model. A token-embedding table does not retain the backbone's contextual computation. Decoder-to-encoder adaptation can supply a callable export, but its reasoning preservation must be tested separately. Diffusion donors add another interface possibility: the masked/noisy state, conditioning and refinement schedule are part of their computation. A final embedding alone need not retain that process. For a concrete masked-token reverse-process example, see Nie et al., *Large Language Diffusion Models*, 2025, [method and sampling](https://arxiv.org/html/2502.09992).

**Closest specialized-encoder precedent:** Fallahpour et al., *BioReason*, May 2025, version 2 October 2025, [§§3–6](https://arxiv.org/html/2505.23579). Frozen DNA backbones export token representations; a learned projection and LoRA-adapted language model train on supervised reasoning, with selected GRPO runs. DNA-only and text/sequence language-model baselines are included. Reported

benefits vary across donor/backbone/task combinations. This supports the feasibility of useful specialist-plus-reasoner integration, while retaining both backbones and learning the integration. Neither sequential donor addition nor donor-independent assimilation is demonstrated. Explanatory prose is not by itself evidence that the stated intermediate causal mechanism drove the answer.

**Targeted attribution follow-up:** in the examined KEGG methods and tables, questions include variant/gene/network context. A question-only or randomized-encoder comparison was not identified there. This is a control gap, not proof that the encoder is unnecessary. At official code commit `684ff7c09eb1d65e70925c114a7a05a1fcc0403f`, the [formatter](https://github.com/bowang-lab/BioReason/blob/684ff7c09eb1d65e70925c114a7a05a1fcc0403f/bioreason/dataset/kegg.py#L21) sends raw sequences plus the question to the text baseline, versus separate sequence fields plus the original question to the integrated route; supervised targets include reasoning and answer. The [training setup](https://github.com/bowang-lab/BioReason/blob/684ff7c09eb1d65e70925c114a7a05a1fcc0403f/train_dna_qwen.py#L100) supports freezing DNA weights, adapting language-model weights and training the projection. The existence of this mechanism does not isolate what pretraining, the bridge or supplied context contributed.

**Our control correction after dialogue:** swapping DNA alone is not a clean task intervention when unchanged text specifies the original variant; it can create contradictory inputs. Use naturally matched valid examples whose text does not disclose the difference, replace all dependent fields coherently with a corresponding text-only arm, or explicitly define a new task that removes the revealing fields consistently. A gene/pathway match alone is insufficient. Variant metadata plus an accessible reference can determine the sequence, making the encoder's benefit one of accessibility rather than Shannon novelty. Preserve that legitimate benefit while comparing supplied-field prediction or declared reference lookup against the integrated route. No new experiment is selected.

**Task-first contract inspection, 2026-09-13 (following audit e1027).**
The proposed joint task was to import a sequence-dependent functional distinction B into a receiver's pathway-to-consequence operation A, then preserve that use when another donor adds context. We traced the documented PFN1 example instead of assuming that its disease prediction requires A+B. At dataset revision `9f0ef941a362f0e308e11861ed82c36338e23586`, test row 125 asks about a chromosome-17 PFN1 allele in the monomeric-actin/PFN1/filamentous-actin pathway. Its exact question and disease answer also occur in training rows 375, 440, 910 and 936. The disease is amyotrophic lateral sclerosis. The test's sequence differs from those training sequences; train 440 shares its reference sequence. An exact question-to-answer dictionary can answer this one example without DNA. This is a source-level witness, not a benchmark score or evidence the trained model ignores DNA. No other test examples were scored.

Independent verification checked the actual strings: all five pairs have length 4001 and exactly one reference-to-variant edit at zero-based position 2000.

Test 125 changes C to G; train 440 changes C to A on the same reference.
The other three changes are A to C, A to G and T to C. Equality of the disease
label does not imply biological equivalence of these alleles.

| Contract component | What the inspected example supplies | Eligibility consequence |
|---|---|---|
| Old receiver operation A | A disease-labeled gene/pathway question | Existing mechanistic execution competence is not isolated by a correct disease answer |
| Donor distinction B | Reference and variant DNA; generated reasoning describes a particular substitution | The scored disease label does not distinguish these five variants; independently annotated functional effects are missing from these records |
| Coupling A+B | A generated explanatory path grounded in disease annotations | Plausible text is not independent validation of a sequence-dependent causal intermediate |
| Cheap structured route | Exact matching question with a training answer | This documented case cannot establish a need for a richer port |
| Future growth and retention | Proposed additional context donor and continued old pathway use | Not supplied as an evaluated workload; requires a distinct contract |

The [pinned curation
notebook](https://github.com/bowang-lab/BioReason/blob/684ff7c09eb1d65e70925c114a7a05a1fcc0403f/data/KEGG_Data_3.ipynb),
zero-based cell 11, constructs questions from chromosome, network, genes and
variant-gene name, omitting variant coordinates and nucleotide change. It takes
the first disease label from the generated structured record. The generation
prompt in `BioReasoning_DataCuration_KEGG.ipynb`, cells 6/12, already receives
associated disease information. This describes target provenance, not label
leakage into the model's test inputs. The actual PFN1 question does not specify
the nucleotide change, so the earlier contradictory-input warning is conditional
and does not prohibit swapping these naturally matched sequence pairs. Their
shared disease label simply supplies no answer-changing contrast.

The public data contain train/test/validation counts 1159/146/144. The
[evaluation
loader](https://github.com/bowang-lab/BioReason/blob/684ff7c09eb1d65e70925c114a7a05a1fcc0403f/eval_kegg_dna_vllm.py#L27)
combines test and validation, explaining a 290-example evaluation. The inspected
curation notebooks export a single training collection; they do not establish
the released split algorithm or the exact historical model-selection protocol.
Do not infer those from split names. The pinned README promises future original
checkpoints; the checked official collection contains three datasets. An
author-model search returned later protein/cell systems, not a verified original
KEGG receiver. This bounded search does not prove no checkpoint exists elsewhere.

**Disposition:** this example is ineligible for demonstrating the proposed joint
donor contribution. The missing resources are a task-relevant effect contrast
with independent labels, demonstrated receiver competence on its assigned
operation, and a usable corresponding receiver artifact. Do not build a new
receiver or benchmark to hide this absence during strategy. The useful native-
math question is now concrete: which distinctions does the current question
erase, and what later question would require retaining them? This applies the
response-relative identity lens to the task; it demonstrates no latent-space
structure in a model. Source revisions, row locators and hashes are in the ledger.

**A relevant negative:** Azevedo and Loures, *Can LLMs Use Relational Transformer

Embeddings?*, August 2026, [§§3–4](https://arxiv.org/html/2609.00457).
Frozen relational embeddings, a learned projection and LoRA/SFT/RL language-model adaptation did not reliably improve the standalone relational model in the reported tasks. Serialization, context budget and masking mattered. This is evidence against assuming a generic soft-token bridge is sufficient, not against reasoning over relational encoders in general. It makes an explicit interface competence preflight more valuable than immediately scaling training.

**Function references are not self-contained implementations:** Todd et al., *Function Vectors in Large Language Models*, 2023/ICLR 2024, [§§2–3 and Table 7](https://arxiv.org/html/2310.15213), identify compact activations that trigger tasks in an existing model. Some tested vector compositions work and others fail. The authors explicitly distinguish the vector's task reference from the computation executing it. Consequently, moving a function vector need not move its implementation; an unfamiliar recipient may need compatible computation already present. A gain after steering can be valuable elicitation without proving a newly imported algorithm.

**Theory reuse:** Lorenz and Tull, *Causal and Compositional Abstraction*, February 2026, [§6, Definition 46/Proposition 47](https://arxiv.org/pdf/2602.16612), distinguish query-level abstraction from stronger component-level compatibility. This reinforces separating task contracts from mechanism-preserving realizations. We have read the relevant definition and implication, not verified every theorem in the 71-page work. S5's finite coupling argument is an elementary independent certificate candidate, not a claimed new version of this theory.

**Two further precedents delimit where computation is learned.**
[SIMPLE, August 2026 v1](https://arxiv.org/html/2608.19115v1), method and Appendices A–D, trains a 125M-parameter inference model on synthetic multi-view classification episodes. SIMPLE-F jointly processes labeled support and unlabeled queries without weight updates; SIMPLE-A calibrates on support. Fixed projected inputs and contextual computation remain work. The separate cross-domain study trains a target classifier. Feature/descriptor and omics benchmarks do not identify pinned pretrained encoder exports or test successive contributor arrivals.
The prior samples 1–16 views; missing-view experiments do not establish arbitrary new-donor growth. Joint sample attention supplies no demonstrated query-batch invariance or reusable cached support summary. Downstream efficiency excludes synthetic pretraining; total pretraining steps, hardware and elapsed time are unspecified in the inspected source. These limits leave positive reusable classification inference intact, while cumulative retention and amortization remain open. Root and an independent reader checked these details. Previously inspected paper links exposed no project-specific checkpoint/code; no new release search or reproduction is selected. This is a constructive initial investment to compare with repeated task learning, not a ready local artifact.

[TransNAR, June 2024 v1](https://arxiv.org/html/2406.09308v1), §§3–4, trains cross-attention and a 70M text receiver around a frozen graph reasoner. Text and solver-ready graph convey the same problem; the hybrid receives both. Reported

improvements include Transformer-held-out sizes, but size 14 lies below the reasoner's pretraining size ceiling of 16. Random initialization ablates the **Transformer**, not the reasoner. The paper reports no random-reasoner, raw-graph-only, cardinality-only, matched-extra-capacity, shape-constrained or symbolic-tool comparator. Invalid output shape forces task score to zero, so better shape recovery contributes to the gain. Fusion variants did not improve its original combination. Although §3 equations depict evolving graph states, §4.1 describes every cross-attention layer reading final reasoner states and suggests stepwise access as future work; the paper alone leaves that presentation ambiguity unresolved. This is positive evidence for the trained hybrid's usefulness over its Transformer comparator, not an isolated causal effect of algorithmic pretraining, direct-tool superiority, preserved interventions or cumulative donors. Root and an independent reader checked this scoped version; no reproduction.

**Specific attribution question, not a new theorem:** distinguish the useful contribution of the whole port from the contribution of its pretraining. For a learned receiving procedure, matched graph access and training budget matter: replacing the reasoner while freezing an interface specialized to it can test interchangeability but cannot by itself tell whether equivalent useful learning was available from the alternative port. Conversely, relearning the interface changes what effort was required. Decide which of these acquisition choices is the target before choosing the control. Shape support is useful behavior; isolating content accuracy must not redefine that usefulness away. This source case is a place to work out contribution and acquisition effort, not a queued large training run or another search for convenient downloadable artifacts.

**Bounded follow-up question, stated before source inspection.** A learned algorithmic processor could earn a practical role by avoiding a costly or lossy conversion from perceptual/uncertain inputs into a solver-ready problem. This is an unestablished proposition about acquisition effort and useful computation, not a general separation from structured distributions, programs or tools. Inspect the original neural-algorithmic-reasoning motivation and one executed latent-planning precedent for what is actually demonstrated: what the input encoder learns, what computation is pretrained/reused, what supervision the receiving task pays for, and which comparison isolates the purported benefit. This targets reasoning over rich encoder states, not checkpoint availability.

**Source outcome, 2026-09-14.** Veličković and Blundell, [*Neural algorithmic reasoning*, Patterns 2021](https://pmc.ncbi.nlm.nih.gov/articles/PMC8276006/), “Algorithmic bottlenecks” and “The blueprint,” propose training a processor on synthetic algorithm execution, freezing it, then learning new raw-input encoders and output decoders around it. Their motivation is that prematurely reducing uncertain observations to scalar solver inputs can impair downstream decisions. This is a perspective and proposed mechanism, not an independent experimental confirmation of the cited planner or a general theorem against explicit tools.

Deac et al., [*Neural Algorithmic Reasoners are Implicit Planners*, NeurIPS 2021](https://papers.nips.cc/paper/2021/file/82e9e7a12665240d13d0b928be28f230-Paper.pdf),

§§3–4, implements XLVIN: retain a frozen value-iteration processor trained on synthetic graphs; learn observation encoders, latent transitions and policy/value heads through task interaction. Reported low-data benefits over PPO and ATreeC span control and pixel observations. The same random-graph-trained processor is reused, while surrounding task learning remains payable. Random **graphs** do not mean random executor **weights**. No random-executor or equal-total-compute comparison isolates algorithmic pretraining. Maze value decoding and scalar-versus-latent Gaussian-noise tests are diagnostic, not interchange evidence. §3 also acknowledges that an expected successor embedding may not support further expansion in stochastic environments; breadth-first expansion grows exponentially with depth. The [supplement](https://papers.nips.cc/paper/2021/file/82e9e7a12665240d13d0b928be28f230-Supplemental.pdf), E–H, specifies synthetic graph construction and downstream training, without fully accounting for executor pretraining. This is a positive complete-recipe precedent, not demonstrated cumulative acquisition into one retained receiver.

**What this changes in our strategy.** A receiving representation can be learned around a reusable operation, rather than first finding an accidental alignment between independently trained spaces. That is a constructive candidate for the next-space lens. This particular processor was deliberately taught an algorithm; it does not demonstrate recovering an unknown reasoning operation from a general pretrained encoder. Repeated representation learning, imported operation fidelity and benefits over appropriately trained structured alternatives remain distinct questions. Its success merits studying the learned interface; lack of isolated pretraining attribution does not erase the complete recipe's usefulness.

The denizen's proposed next distinction is concrete: a state summarizing possible outcomes must support the **next** operation, not merely represent a plausible average now. The paper itself exposes this concern for stochastic transitions. Likewise a robustness curve in arbitrary coordinate units is not yet an invariant measure of the effort needed to change a behavior. These are targeted interface questions suggested by a positive mechanism, not reasons to launch another model or generic latent-space measurement suite.

**S8.1 — conditional proposition: when can an expected latent state be advanced?** To sharpen the source's stochastic-transition limitation, fix a finite state set S, an encoding z:S->R^d and an action a with transition kernel P_a. A belief b over S is exported only as `m(b)=E_b[z(s)]`. Require a receiving operation F_a to return the next expected encoding for **every** finitely supported belief:

`F_a(m(b)) = E_{s~b,s'~P_a(.|s)}[z(s')]`.

The necessary and sufficient condition is that the conditional next-feature expectation `g_a(s)=E[z(s')|s,a]` be affine in z(s) on this support. This asks whether the permitted move descends through the mean export, rather than whether nearby vectors look alike. The all-beliefs premise matters; a restricted deployment family can require less. No such property is assumed of XLVIN's learned encoder or transitions. This is a finite operational-closure calculation, not an empirical claim or a proposal to build another toy environment.

**Proof.** If `g_a(s)=A_a*z(s)+c_a`, taking expectations supplies `F_a(m)=A_a*m+c_a`. Conversely, any coefficients alpha_s with zero total and `sum_s alpha_s*z(s)=0` split into equal-mass positive and negative parts. After normalization these give two beliefs with identical m. A well-defined F_a requires their expected g_a to agree, hence `sum_s alpha_s*g_a(s)=0`. Preserving every affine dependence makes z(s)->g_a(s) an affine map on the affine hull of z(S). F_a is thereby determined on its convex hull, with no obligation on inputs outside it. This also handles noninjective z: indistinguishable states must have identical expected successor features. It is existing affine and predictive-state scaffolding, independently checked, not new latent mathematics. Arithmetic averaging is itself a coordinate convention. The proposition tests that declared export; a probability law can instead be transported through a changed encoding without identifying its average with an ordinary state.

**The next operation can break a previously sufficient mean.** For encoded states -1,0,+1, compare the equally weighted endpoint mixture with a point mass at 0. Both export mean 0. A deterministic transition taking both endpoints to +1 and leaving 0 fixed gives next means 1 and 0: no function of the old mean can perform this particular move for both beliefs. Additional features or preserved branches can remove this witness; it does not refute learning a better encoding.

There is a distinct observation-timing obligation even with identity transitions. Let two available actions pay z(s) and -z(s). Both expected payoffs are recoverable from the mean, so the best action chosen **before** observing the state has value `max(Ez,-Ez)=0` for both beliefs. If the state is observed **before choosing**, the value is `E|z|`: 1 for the endpoint mixture and 0 for the middle point. Mean-state closure for fixed actions therefore does not establish adequate conditional choice. This stronger operation is relevant only when the stipulated observation is actually available; it must not grant the receiver future knowledge.

For this three-state support, adding the feature |z| distinguishes the beliefs; it is not a universal remedy for new states or further operations. This clarifies growth: add the distinction required by a new usable operation, rather than presuming every donor can be averaged into an unchanged state type. Possible realizations include richer features, explicit weighted branches, or querying the source again. Their acquisition and continuing costs remain empirical. The calculation qualifies a declared mean-only interface, not the tested planner's actual learned states or the feasibility of encoder-based reasoning.

**Question that motivated the completed prior-art check below.** If representations are learned around useful operations, what training target makes continuation quality the object being preserved? A reward/latent-transition objective is an existing candidate, not a new invention. Inspect its actual sufficiency assumptions: distributional transition error versus error of a mean, which task/policy family is covered, and which support the training data must reach. The intended decision is which operational contract a future co-designed space should learn against, not selecting an architecture or starting representation training here.

**Existing sufficient-contract route.** Gelada et al.,

[*DeepMDP*, ICML 2019](https://proceedings.mlr.press/v97/gelada19a/gelada19a.pdf), §§2–5, use reward error and Wasserstein error of the **full pushed-forward latent successor distribution**. Global value bounds concern latent policies with Lipschitz values; the optimal-policy bound additionally assumes a Lipschitz latent MDP with `gamma*K_P<1`. Local bounds use the evaluated policy's state-action occupancy, not arbitrary future coverage. These are discounted-return guarantees, not preservation of every trajectory query. §7 experiments assume deterministic transitions and use gradient penalties, which do not certify all theoretical premises. Atari results use the objective as an auxiliary to C51; latent planning is not the evaluated mechanism. The four-track example reports near track-invariance under identical dynamics/rewards, not exact empirical collapse. Root and an independent reader checked the main theory/experiment scope; no full proof audit or reproduction. This supplies a serious pre-existing co-design target, rather than evidence that a new latent objective has been invented here.

**Our growth inference.** A representation can correctly discard which track an agent occupies when all relevant dynamics and rewards agree across tracks. A later track-specific question or reward need not be recoverable from that abstraction. That is task-relative compression working as intended. New rewards remain usable if they admit an adequate readout on the old representation; new actions need corresponding transition obligations. Otherwise retain a route to recover/refine omitted distinctions. Even predicting the full **latent** successor distribution does not restore information already discarded by the encoding.

This gives two constructive cases to keep distinct: a new objective expressible through old features may reuse existing computation; a new distinction can require refining the space. Before treating either as novel, inspect the explicit transfer mechanism of successor features and generalized policy improvement for the first case. The bounded question is whether it actually composes useful actions across previously trained policies, what common semantics it assumes, and what learning or continuing evaluation it still needs. No policy training or architecture build.

**S8.2 — proposition attempt before checking a growth guarantee.** For one fixed discounted MDP and exact action values of stored policies, define GPI(L) to choose `argmax_a max_{pi in L} Q^pi(s,a)`. Does L contained in L' imply that the policy GPI(L') performs at least as well as the already composed GPI(L)? The standard guarantee against individual stored policies is a different statement. Check this distinction before importing library growth as retention. This is a bounded mathematical source check, not an empirical toy benchmark or model run.

**Primary source read.** Barreto et al.,

[*Successor Features for Transfer in Reinforcement Learning*, NIPS 2017](https://papers.nips.cc/paper_files/paper/2017/file/350db081a661525235354dd3e19b8c05-Paper.pdf), §§3–5, factor policy values as expected discounted feature counts times reward weights. Transfer assumes common dynamics, actions and reward-feature semantics; new reward weights are supplied or learned. Theorem 1 bounds GPI against each stored policy under the **current** reward and uniform value-estimation error. Experiments report useful sequential navigation transfer and new reacher targets;

the latter supplies features for all target locations and updates all four successor-feature models from each transition. This is meaningful within-family reuse, not arbitrary encoder grafting, new feature acquisition or donor removal. Root read the main mechanism, theorem statements and experiments. The following check concerns §4.2's stronger subset-policy inference, not its empirical scores.

**Exact counterexample, independently derived and fresh-CLI audited.** Use discount .9, states u,s,x,y,z,terminal and actions 0/1. The table gives `next state, immediate reward`:

| State | Action 0 | Action 1 | pi1 action | pi2 action |
|---|---|---|---|---|
| u | s, 0 | s, 0 | 0 | 0 |
| s | x, 0 | y, 0 | 0 | 1 |
| x | terminal, 1 | z, 0 | 0 | 1 |
| y | terminal, 2 | terminal, 0 | 1 | 0 |
| z | terminal, 10 | terminal, 0 | 0 | 1 |
| terminal | terminal, 0 | terminal, 0 | 0 | 0 |

At s, pi1's action values are (.9,0); pi2's are (0,1.8).
GPI({pi1}) therefore chooses x, but at x improves to action 1 because its values under pi1 are (1,9). At z it takes reward 10. Its realized value from s is 8.1.
GPI({pi1,pi2}) instead chooses y at s and then reward 2, for realized value 1.8.
All decisive choices are strict. At predecessor u, either forced first action gives Q_old=7.29 versus Q_new=1.62, so the stronger Q-function comparison also fails. The constituent policy values at u are .81 and 1.62; the new GPI policy still satisfies Theorem 1 exactly. The theorem remains intact.

Both constituents can be optimal for previous tasks with shared dynamics and common one-hot state/action features: source task i pays zero for pi_i's chosen actions and -1 otherwise. The selected policy attains the maximal value zero. Those rewards and the current target reward all use the same feature family. Thus assuming source-task optimality does not repair the stronger inference. Nor is approximation, training noise or a changed coordinate system responsible.

The increased envelope of stored values is a better lower bound against stored policies; it is not the realized value of the old or new composed policy. This refutes monotonicity of **recomputed one-pass GPI under library inclusion**, not policy iteration after re-evaluating the improved policy or the usefulness of successor-feature transfer. It does not establish a failure in trained models.

**Constructive retention obligation.** Include the previous executable composed policy g as a library member and evaluate every member's Q under the same current objective. With uniform action-value error at most epsilon, the next GPI policy h satisfies

`V^h(s) >= V^g(s) - 2*epsilon/(1-gamma)`,
`Q^h(s,a) >= Q^g(s,a) - 2*gamma*epsilon/(1-gamma)`.

The Q statement is a slightly sharper consequence than the paper's stated bound; the state-value statement needs its own argument. Let W=max_i V^i and H=max_i Q^i. Approximate greediness gives `H(s,h(s)) >= max_a H(s,a)-2*epsilon >= W(s)-2*epsilon`. Also the policy Bellman operator satisfies `T_h W >= H(.,h(.))`. Contraction

therefore gives `V^h >= W-2*epsilon/(1-gamma)`; conditioning on a forced first action supplies the Q bound. No arbitrary pointwise Q comparison was substituted for a deployed-return argument.

Merely retaining policy code or the old envelope does not supply the composite's evaluation; learning its successor features also costs work. An evaluated old composite dominates its old constituents in the exact case, but need not dominate new additions. Reduction to ordinary single-policy improvement requires that extra dominance condition. Changed rewards protect g's value under the **new** reward, not its earlier numerical return; successive approximation losses can accumulate. The fresh CLI audit verified the witness, source scope and these qualifications without a numerical benchmark. Retaining constituent skills and retaining achieved composed behavior are different acquisition obligations.

## S9. Information gain versus new internal algorithm

The third reviewer dialogue distinguishes three candidate probes:

| Probe family | What a positive result could establish | Cheapest serious rival |
|---|---|---|
| A. Partitioned evidence | A live channel contributes otherwise unavailable information | Verbatim evidence forwarding or structured fields |
| B. Reusable operation and new compositions | Donor-conditioned operational gain under a declared budget | Bounded recipient elicitation, then learning from the same supervision |
| C. Specialist encoder with an existing reasoner | Useful access to distinctions through a reusable interface | A small structured readout followed by the same reasoner |

No family is selected yet. A is cleanest about information provenance but often permits an easy text solution. B is close to the ambition but hard to identify as an *internal algorithm* transfer. C is promising when specialist evidence is hard to express compactly before the downstream question is known.

Even a post-freeze random rule does not settle B's attribution. A recipient may already implement a general interpreter; acquisition supplies a new program, not a new interpreter. One bit can select between two existing operations. Thus donor dependence, frozen recipient weights and novel held-out uses together still do not prove that the underlying algorithm was absent before acquisition. The measurable initial endpoint is **new usable behavior under a declared elicitation, learning and resource budget**. This is a legitimate objective; algorithm-transplantation language requires additional causal identification.

The question that now seems most discriminating is: **which export remains useful when the downstream question changes, and how cheaply can that export be extended when a new donor adds a distinction?** This connects encoder reuse to the original continuation-based mathematics without requiring a fixed universal geometry or an unnecessarily strong simulation of donor internals.

## S10. A reusable export pays for questions it has not yet seen

**Definition attempt S10.1 — question-relative sufficiency.** Let x be source evidence, q a downstream question, and y the desired response. An export E(x) is sufficient for a question family Q if the desired response law can be recovered from `(E(x),q)` throughout the declared support. Operational sufficiency additionally restricts the reader's learning and inference budget;

existence of an arbitrarily expensive decoder is not enough. For interacting systems replace q by the permitted continuation/context family from S5.

An export E(x,q) computed after seeing q solves a different problem. It can omit information irrelevant to that question. Success of query-conditioned cache communication does not establish a reusable query-independent knowledge store. Conversely, a store that supports arbitrary future queries may need more space or retained donor access. This distinction cuts across text and latent channels.

**Elementary counting attempt S10.2.** Suppose x is any N-bit string, an export is a deterministic B-bit message computed before the query, and a decoder must answer every coordinate query `q=i` exactly, with no other x-dependent resource. Then B>=N: if B<N, two distinct x values share a message; they differ at some coordinate i, where the same decoder input would need two different answers. If q is known before export, sending the requested bit needs only one bit. This is a worst-case exact illustration, not an empirical verdict on compressed models; structure, approximate answers and restricted queries can reduce cost. Finite precision matters: a real number with unbounded precision is not a one-bit message. Model weights, indices, adapters and caches are all information storage when they depend on the donor.

**Approximate extension S10.3, analytical only.** Let X be N binary answers, S the recipient's existing retained information, and M a fixed-length B-bit export available before the queried coordinate is known. Suppose answers computed from (S,M) have mean bit error at most epsilon <= 1/2. For the binary entropy function h2, the ordinary information bound is `B >= H(X|S) - N*h2(epsilon)` (or zero if the right-hand side is negative). For each coordinate, its error flag determines the true bit given the predicted bit; hence `H(X_i|S,M) <= h2(error_i)`. Conditional entropy is subadditive, and concavity of h2 bounds the sum by N*h2(epsilon). Subtract from H(X|S) and use `I(X;M|S) <= H(M|S) <= B`. No model experiment is needed for this argument.

This makes the role of overlap explicit. Truly unpredictable additional answers require retained information at fixed error; redundant answers can be compressed. If answers are generated by a short reusable rule, their joint entropy need not grow like the number of queries. When the donor merely makes information already in S easier to compute, the bound can be vacuous; S19's accessibility and total-cost questions then matter. The bound applies to this stated binary query family, not model parameter counts, all pretrained knowledge or an unknown future workload. An API that recomputes an answer after seeing the query uses a different resource contract. Do not compare its one-answer message size with a query-independent release while ignoring the retained donor computation.

**Native interpretation:** every new kind of question can require splitting places the old world treated as identical. The persistent system need not keep all raw evidence, but it must either preserve the distinctions that future questions need, recover them through continued access, or accept a stated loss. "Constantly adding knowledge" therefore requires a policy for the growth of distinctions and their cost, not just another alignment matrix.

Related existing theory should be reused rather than renamed. Banerjee and Montúfar, *The Variational Deficiency Bottleneck*, 2018, version 3 November 2020, [§§II–III](https://arxiv.org/html/1810.11677), develop channel approximation and its decision-risk interpretation. Our extra research obligations are restricted executable readers, changing questions, repeated acquisition and causal usability in actual model interfaces. We have not established that these obligations require a new theorem rather than a suitable application/extension of existing theory.

**Discriminating test design, not a selected run:** compare a query-conditioned export, a fixed reusable export, and retained on-demand encoder access on the same source items. Change the downstream question family after acquisition. Match information access and account for the conditional export's recomputation. A reusable export holding up on new questions is stronger evidence for the growing-space ambition than a channel optimized only for the final answer.

### S11. Observing a state does not make it writable

The obvious next idea is to use future-test predictions as coordinates. This has already been examined in [CR-15.10](CONTINUATION_REFINEMENT.md), including PSR/OOM prior art, finite-panel limits, inverse observability and conditioning. Repeating that theory or fitting a Hankel matrix without a new acquisition decision would be a return to old measurement apparatus.

For orientation, Ayache, Eyraud and Goudian, *Explaining Black Boxes on Sequential Data using Weighted Automata*, 2019, [§§2–3](https://proceedings.mlr.press/v93/ayache19a/ayache19a.pdf), extract weighted-automaton approximations through queries to a sequential black box. This supplies a relevant model-extraction baseline; it does not provide a general graft into a different frozen recipient. A finite empirical matrix's low rank is not proof that it spans all future queries.

**Missing acquisition obligation:** even perfect knowledge of a desired response profile does not imply that any allowed recipient intervention can realize it. Observability concerns distinguishing states. Writeability concerns reaching a state or constructing a component that produces the required behavior while preserving designated old behavior. They are separate. A response predictor can be excellent while the recipient has no usable input port for its prediction.

**Definition attempt S11.1 — feasible acquired behavior.** For an allowed integration family U and budget B, let `F(R,U,B)` be the set of task-context response laws realizable by integrating with recipient R. A proposed donor contribution must be adequately approximable within this set while meeting the retention contract. This definition isolates the question; it is not a tractable test or a claim that unsuccessful optimization characterizes the whole set.

Two acquisition routes can satisfy it differently: add an executable external component, or modify/inject a recipient state through a learned port. The former can work even if the latter is infeasible. Neither requires all donor internals to share the recipient's geometry. A small response-test basis becomes useful only if it lowers the cost of selecting, learning, or validating such a usable

interface. Otherwise it remains a measurement surface.

**Reviewer refinement (audit e962–e963):** a new question is recoverable from a profile P precisely when its response is constant on P's fibers over the declared domain; an affordable reader is an additional requirement. An action requires the successor profile `P(T_a(x))` to factor through P as well. New donor support can break these properties even when the question names stay unchanged. Questions that change the state require resets or independent copies before their answers can be treated as one profile.

For a linear approximation `f_q = c_q^T P + r`, coordinate error at most delta and residual at most eta give error at most `||c_q||_1 delta + eta`. Small rank does not imply stable or cheap use. More generally, an L-Lipschitz reader with error eta requires target separation between two items to be at most `L * profile_distance + 2 eta`. Violating this refutes that declared reader contract, not every possible representation. This is familiar mathematical scaffolding. The operational question is which necessary distinction or move it diagnoses. Choose the useful receiver operation before collecting a basis.

**Growth corollary, not a new theory block.** Adding information can break the sufficiency of an old transition port. For example, T(a)=c, T(b)=a, T(c)=c admits a one-place quotient; newly distinguishing c leaves {a,b} with no unique successor block. Refining by future observations repairs it through the existing continuation construction. For finite stochastic kernels and arbitrary starting laws, the corresponding requirement is equal transition probabilities into each quotient block, not merely equal means of selected features. This is familiar quotient/lumpability scaffolding, independently checked, not learned-model evidence. It changes an acquisition decision only if the new distinction must be advanced without source requery. Current readout can still be useful without that contract; otherwise charge richer maintained state, transition learning or continued access.

## S12. What a model provider would actually export

The user's retired-model example motivates an access contract, not a prediction of any provider's release policy. "The embedding space" is underspecified until the callable map, input domain, observations and retained computation are named.

| Export | What it permits | What remains absent unless separately supplied |
|---|---|---|
| Token embedding table | Map known token IDs to their input vectors | Contextual backbone computation, reasoning dynamics, usable output behavior |
| Finite paired input/vector bank | Learn/use correspondences on stored support | Fresh contextual encoding of arbitrary inputs and unobserved operations |
| Callable contextual encoder API | Encode new inputs with donor computation retained remotely | Weight access, internal restart/intervention, offline independence |
| Frozen contextual backbone weights | Reproduce its supported forward computations locally | Automatic small size, a compatible recipient port, proof of retained task behavior after conversion |
| Distilled encoder or compact executable component | Reuse behavior within a trained export contract | Lossless preservation of all donor knowledge; free creation of the export |
| Typed capability API with response examples | Invoke declared operations and test their meanings | General access to unexposed capabilities or donor-independent execution |

A useful research export should declare revision, tokenizer/preprocessing, layer/pooling or output semantics, precision, input support, query/session/reset behavior, and which observations/interventions are available. Paired records need stable identities. The cache probe shows why these are scientific requirements: finite numbers and matching shapes do not establish faithful representations, and matching score files do not establish row semantics.

This contract does not dictate a format or implementation. It lets us ask a concrete question of each possible donor: **what new useful behavior could this export make available, what would integrating it require, and what information would no longer be recoverable if the original donor disappeared?**

**Conditional size calculation, not a claim about a proprietary model.** Suppose a contextual backbone has P unique parameters excluding a vocabulary embedding matrix E of shape V by d. If its output projection is tied to E, retaining the input embedding and backbone still retains `P + V*d` unique parameters after the output projection operation is removed. There is no unique-weight saving from deleting that tied head. With a separate output matrix, removing that matrix saves its parameters, while the contextual backbone remains. This is parameter bookkeeping, not a runtime benchmark or a lower bound on possible compression.

Computing contextual features once can avoid repeated autoregressive generation and the output projection, but does not remove the attention/feed-forward work needed to encode a fresh input. Architecture, sequence length, cache use and the receiving computation decide total cost. "Release the embedding space" can thus mean a useful contextual feature service or backbone release without making the model small. A smaller executable export requires an actual compression or distillation result on a declared future-use contract. No architecture or release policy is inferred for the user's retired-model example.

### S13. Growth is a sequence of usable extensions, not a donor count

**Close assimilation precedent, bounded source follow-up:**
[Roth et al., Fantastic Gains, ICLR 2024](https://arxiv.org/html/2310.17653v2), sections 3–5.2, studies distillation between already pretrained ImageNet models. Its retention method partitions examples between donor targets and a frozen copy of the initial student, using confidence or label-based selection. Three sequential teachers improve tested students, with diminishing returns and forgetting. Positive prediction flips are their task-specific complementarity measure, not knowledge units or guaranteed extractability. Shared labels and transfer inputs supply correspondence; this is a substantive baseline for cumulative assimilation, not heterogeneous operation composition or training-free grafting. The official repository at
[ec9ab8ca38af651b290759fd0a168b467617109d](https://github.com/ExplainableML/General-Knowledge-Transfer/tree/ec9ab8ca38af651b290759fd0a168b467617109d)
contains only README and LICENSE, with no releases in the checked official surface. Independent source inspection confirmed this bounded availability verdict. Retain the precedent; do not start a reproduction project.

**Definition attempt S13.1 — conditional acquisition value.** Fix evaluation

contexts C, a utility functional V, and a resource accounting convention. For an integration procedure I and already acquired donor set S, define the measured conditional gain of D as `V(I(S + D)) - V(I(S))`, with matched recipient access, training evidence and evaluation contexts. This quantity depends on the procedure, budgets, ordering and task distribution. It is not an intrinsic number of knowledge units inside D. Storage and ongoing execution are reported separately rather than hidden in a single unmotivated utility weight.

A donor can have zero standalone gain but positive conditional gain: one source may supply an identifier and another the information indexed by it. Conversely, two individually useful donors can be redundant. Thus a screen that rejects every donor with zero individual gain can discard useful combinations. A factorial baseline (neither, A, B, A+B) establishes conditional contributions on the declared tasks, but even a positive interaction does not prove an internal algorithm was transplanted. A text or structured-data join may explain it.

**Proposition attempt S13.2 — incompatible retention demands.** At the same unqualified context, suppose old and new contracts demand output laws p and q. If the acquired system's law r must be within TV tolerances epsilon_old and epsilon_new respectively, the triangle inequality requires `TV(p,q) <= epsilon_old + epsilon_new`. If this fails, no integration method can meet both contracts. The remedy may be a qualified context (source, time, scope), an explicit correction, or revised tolerances. It is not necessarily better alignment. This concerns contradictory specifications, distinct from parameter interference between compatible tasks.

The denizen's world therefore needs not only distinctions and moves but the scope in which a distinction is valid. Retaining an old answer after discovering it was wrong is not the same objective as retaining an old skill. S7's declared correction policy prevents an impossible preservation contract from being misdiagnosed as failure of acquisition.

**Order is an experimental variable.** Compare A then B with B then A only after matching total examples, replay access, optimization and retained resources. Permutation-invariant final weights are unnecessary; test the required behavior and repair cost instead. If later evidence intentionally supersedes earlier evidence, order-independence is not even the intended law. For a third donor, the question is whether extending the existing interfaces needs bounded local repair or effectively relearning all earlier integrations. Two-donor success alone cannot answer that scaling question.

**Relevant baseline, narrower than heterogeneous-model grafting:** Hitit, Girrbach and Akata, *A Systematic Study of In-the-Wild Model Merging for Large Language Models*, version 2 March 2026, [§§3–5 and Appendix F](https://arxiv.org/html/2511.21437v2), study fine-tunes of a shared base separately for each base family. They compare sampled subsets of increasing size, finding modest average improvements from simple task arithmetic under their evaluation. This does not test arbitrary cross-architecture donors, sequential repair cost, or newly joint operations. Their evaluation omits

model-specific chat templates; gains over that protocol should not automatically be treated as gains over each model's best inexpensive elicitation. Shared-base weight merging remains a serious baseline when that access regime applies.

### S14. A usable port before a new universal space

The operation dialogue considered identity-preserving scene updates and scoped assignment updates. Neither presently earns a model run: the former adds perception/data construction uncertainty; the latter overlaps closed temporal memory work and may be fully served by an explicit structured delta. They are worked examples of obligations, not newly selected benchmarks or results. Historical `interchange_v1` failed its baseline before a swap arm; `interchange_v2` failed its fixed single-anchor construction. S14 is a new contract question, not authorization to reopen those closed runs; see the [closure inventory](../docs/HANDOFFS.md#durable-findings-from-the-frozen-model-line).

The material question is stronger than changing readouts: **does an imported distinction remain usable after a receiver operation, so that a later operation can use the resulting state?** Static feature banks with separate question heads can pass readout tests without supporting this requirement.

**Definition attempt S14.1 — component interchange contract.** Start with an independently competent receiver operation consuming a specified port. D1/E1 supplies that port. Replace it by D2/E2 while keeping the receiver operation fixed and declaring a calibration budget for E2. Evaluate both old supported behavior and cases where D2 has a verified useful advantage. Measure whether that advantage reaches the unchanged operation. Calibration must not simply teach E2 all decisive held-out answers; a frozen receiver alone does not rule out task learning inside the adapter.

Replacement tests a stable interface. Extension admits a previously unavailable distinction or operation. Interchange can clarify extension, but it is not a mandatory staircase: a genuinely new modality may have no old equivalent port. Likewise an ordinary external component can be the best realization; an internal latent injection is not required by the acquisition objective.

| Observation under matched access and budgets | Next question |
|---|---|
| Structured port preserves operation and transmits donor improvement | Can this inexpensive port extend while retaining earlier uses? |
| Old operation survives, donor improvement does not | Did export discard it, or can the receiver not act on it? |
| Rich export transmits more improvement than matched alternatives | Which extra usable distinction explains the gain? |
| Neither port enables the proximal operation | Is donor competence, calibration, or receiver access inadequate? |

**No artificial symbolic-versus-latent contest.** Unrestricted structured fields can contain programs, distributions, features or original evidence. Every finite precision latent export can be serialized as bits. A narrow hand-picked schema failing is not a general separation. Compare actual interfaces under the same source access, acquisition budget, storage, recurring compute and required operations. A representation can offer an important practical advantage without being impossible to encode in text. Serialization alone, in turn, does not make

the recipient capable of interpreting it cheaply.

An empirical interchange claim needs an actual donor pair and usable receiving operation that populate this contract. This is a requirement for that experiment, not a prerequisite to mathematical work or to other acquisition routes. Invalid cached pairs remain closed; active routing lives in the Next-work boundary.

**Worked continuation, 2026-09-14 — declared semantic stage, not layer index.** Stipulate a port containing exact minimum hop distances d(s,v), stable node identities and infinity for unreachable nodes. A receiver asks which nodes are reachable within radius k and which become newly reachable at radius k+1:

`B_k(v) = 1[d(s,v) <= k]`,
`N_k(v) = 1[d(s,v) = k+1]`.

The port plus k supplies both exactly, and advancing the request changes k to k+1 without changing d. If k is omitted, the same node at distance 2 requires different B answers at k=1 and k=2, and different N answers at k=0 and k=1. No deterministic reader of d alone can satisfy both omitted-context requests. The missing item is query context, not necessarily a missing latent distinction. Once k is supplied, this stipulated continuation has no remaining information obstruction. A frozen stage-consuming interface may need a conversion; permitted receiver adaptation can instead consume distances directly. Neither choice needs to imitate the donor's internal algorithm. Conversion work still counts.

Even providers solving the same problem need not share an iteration clock. Initialize distances at (s,a,b)=(0,infinity,infinity). A simultaneous relaxation round reads old distances; an ordered sweep updates a then b using new distances. On s->a->b, one ordered sweep reaches (0,1,2), requiring two simultaneous rounds. On s->b->a, it reaches (0,infinity,1), matching one simultaneous round but not two. Thus no single choice of simultaneous-round index matches the first ordered sweep on both graphs. This ordinary algorithmic example refutes that specific clock-matching rule, not graph-conditioned adapters or richer hidden-state maps. Use the semantic radius observation above if that is what consumption requires.

These calculations close the alleged stage-information obstruction for this contract; they are not a new learned latent law. S8's final **hidden** states are not established to be equivalent to decoded distances. Final-state access avoids an intermediate-clock obligation, but does not prove answer-only access is adequate for the trained hybrid. If evolving states matter, identify the required observations before assuming iteration or layer correspondence.

**One further operation: edit the graph, then ask again.** The proposition to test on paper is whether the same distance export remains sufficient when an edge can be deleted. Unlike advancing a radius, this changes the problem itself. Take directed graphs on (s,a,b,c,t). Both contain edges s->a, a->t, s->b, b->c; G1 additionally contains c->t, while G2 does not. Both export distances `(0,1,1,2,2)`. Even all edges lying on shortest paths from s are identical: c->t is absent from that set because it supplies a longer route to t.

Delete a->t in both graphs. Now G1 has distance 3 to t through b,c, while t is

unreachable in G2. The old distances, shortest-path edges and named deletion are identical, but the required answers differ. No reader of those resources alone can supply both correct answers. This is a concrete instance of S11's existing successor-factorization condition, not a new general impossibility theorem. The changed operation has exposed a distinction the old answer contract omitted.

The remedy is explicit: retain graph access and recompute/query the donor on the edited graph, or export additional information adequate for the declared edits. A particular extra detour resolves this pair; no claim is made that a fixed small detour list handles every graph or edit sequence. Repeated donor calls and maintaining richer state have different costs, not a demonstrated winner. S8's hybrid already receives the graph, so this is **not** evidence of an information deficit in that model. There, any obstacle would concern affordable use of available information, as S19 distinguishes. We have not established which information its hidden states retain or whether it supports graph edits.

The paper case closes with two different acquisition contracts: final distances plus radius suffice for the stated continuation; editing the source requires additional access or retained distinctions. A port's adequacy depends on the future operations, not only its current answer accuracy. This makes the denizen's question concrete: two maps can list identical travel times yet differ in which detours survive a road closure. No model run follows from this analytical witness.

### S15. A fixed hub need not mean a fixed set of distinctions

**Concrete precedent:** Girdhar et al., *ImageBind*, CVPR 2023, [§§3–6](https://arxiv.org/html/2305.05665), freeze image/text encoders and train other modality encoders through image-paired contrastive supervision. They test cross-modal classification/retrieval and illustrate audio exports driving existing detection/generation interfaces. This demonstrates useful interface reuse, not arbitrary donor grafting or sequential retention. Their discussion identifies task adaptation and additional pairing sources as further work.

**Conditional obstruction S15.1.** Let H(x) be the old hub observation and Z(x) the complete permitted source-dependent deployment resource. Assume its channel law factors through H, with no other source-dependent side channel. If two situations have the same H but desired output laws separated by TV distance Delta, every downstream reader has worst-case TV error at least Delta/2. Both situations induce the same reader law; apply the triangle inequality. Include source-dependent adapters, caches, session state and retained donor calls in Z. Leaving an information path out would invalidate the premise.

More generally, if the two complete resource laws have TV distance at most delta, data processing and the triangle inequality imply `Delta <= 2 epsilon + delta` for a common reader with error at most epsilon on both. Nearby vectors in cosine/Euclidean distance do not establish this TV premise. In particular, two distinct deterministic vectors can have TV distance one regardless of their small geometric separation.

**Why this is not a no-go for fixed-dimensional alignment:** a donor exporting

into the same ambient vector space need not compute its export from H(x). It can retain distinctions unused by old readers. A contrastive objective alone does not imply hub-only factorization. Whether extra distinctions survive training, finite precision and affordable decoding is a separate empirical question. Do not turn a conditional information bound into a verdict against ImageBind or shared spaces.

**Operational extension criterion:** P' should admit an interpretation preserving old P interactions, distinguish new situations sufficiently for an affordable reader, and preserve successor information needed after updates. Old places may split into new places with a forgetting map back to their old meaning. Extra coordinates are optional; extra usable distinctions are essential. This is an operational constraint on acquisition, not a newly claimed mathematical theorem.

**Conditional small falsifier, not a selected run:** use cases with identical actual hub input but different competent donor evidence requiring different answers. Compare donor export, replacement by the hub export, an explicit donor readout, and donor evidence swapped within matched pairs. Split source groups; create export before the changed question. Donor-swap-sensitive success beyond the hub-only arm refutes hub-only factorization for the tested interface. It alone does not establish reusable updates or cumulative reasoning. Failed readout does not prove information loss. Merely selecting nearby hub vectors would confound the test with unmeasured hub information.

Independent reviewer /root/cache_integrity_review developed this distinction and falsifier after reading the primary source; root records the finding to avoid concurrent blackboard writes. No model or new data run was selected.

### S16. Closer precedents sharpen the missing evidence

**Another decoder donor can improve a fixed visual operation.** Ruthardt et al., *Better Language Models Exhibit Higher Visual Alignment*, TMLR 2026, [§§3–5 and appendices](https://jonaruthardt.github.io/assets/pdf/ShareLockPaper.pdf), freeze vision/language backbones and separately train projections for language variants. Their controlled study holds out alignment classes; ShareLock uses a larger caption-trained projection. The visual computation and cosine decision rule stay fixed, but the donor-specific adapter changes. Reported projection training time excludes substantial feature extraction; fixed label caches only amortize repeated label sets. Their compositional evaluation remains weak. Independent source review: /root/cache_integrity_review. This is a useful S14 classification precedent, not evidence of sequential retention or state updates. The next question is complementary usable gains versus simply selecting a better single donor or combining scores, not reproducing another alignment table.

**Operator names do not establish reasoning laws.** Huang, *DODR*, September 2026, [§§7.2, 7.6, 11.1, 19.1](https://arxiv.org/html/2609.04782), uses frozen DistilBERT snapshots, supervised matrix operators and candidate-snapshot cosine retrieval. The small self-built evaluation uses one seed and lacks controlled baseline systems. Independent source triage: /root/strategy_questions_review.

This supplies a supervised operator baseline idea, not cumulative acquisition. Our logical check: determinism alone cannot guarantee correctness; a deterministic map can consistently give the wrong answer. No broader proof audit is needed to reject that inference.

**Learned discrete ports over frozen features are relevant.** Kaszynski, *Emergent Compositional Communication for Latent World Properties*, 2026, [§§3–5](https://arxiv.org/html/2604.03266), trains senders and receivers on property-comparison tasks over frozen visual/video features. Factored messages, receiver resets and property-specific comparison supervision shape the protocol. The work includes new receivers over frozen messages, action-conditioned outcome prediction and real-video validation. These are useful learned-interface precedents. They do not establish a transplanted pretrained reasoner, unchanged receiver transfer to every new task, or sequential donor retention. Zeroing a message tests influence; it alone does not prove a legal, selective replacement operation. The paper's failed single-message bin classifier motivates S17's anchor diagnostic rather than a conclusion that absolute information is absent.

The linked repository has later onboarding claims beyond the paper. Treat those as separate versioned evidence, inspected at commit `ca36be0b86eee76425f6aad3f37c634cdbcc8a0f`; do not conflate its newer protocol with the paper's experimental setup. Code inspection and saved-result interpretation are completed in S18; no external script was executed or model loaded.

## S17. A relative code may admit an absolute reader with anchors

**Proposition attempt S17.1.** Let a property take ordered values `v1 < ... < vm`. Retain a labeled anchor message ai at each vi for i<m. Suppose a deployed comparator receives only query message z, ai and a fixed property specification, and correctly computes the strict predicate `v(z)>vi`. Then `rank(v(z)) = 1 + sum_i 1[v(z)>vi]`. Thus a correct finite order interface plus labeled anchors gives a rank reader. Numerical values additionally require the labeled dictionary. This is a constructive accessibility diagnostic, not a new theorem or evidence that any particular model meets the premises.

If threshold error Ei occurs with probability epsilon_i under the actual anchor/query deployment law, rank error is at most `sum_i epsilon_i` by a union bound; independence is unnecessary. Errors can cancel, so the bound is sufficient, not necessary. Average accuracy on randomly paired examples does not establish these anchor-specific errors. A comparator that excludes ties has not shown the required strict-threshold behavior when the query equals an anchor value.

Stored-anchor compatibility matters: jointly encoded pairs, changed context or shared session randomness may invalidate reuse. Count anchor labels/storage, comparator weights and calls. The construction distinguishes representational absence from expensive accessibility; it does not beat a cheap learned reader merely by existing. Independent dialogue with /root/strategy_questions_review checked these qualifications. No empirical anchor test is selected.

**Cross-property calibration is an extra resource.** Independent increasing

transformations preserve each property's within-property comparisons but may change comparisons between properties. For example, shifting every value of A by ten leaves A's ordering intact while changing whether A exceeds B. Therefore within-property agreement alone does not identify cross-property meaning. Shared units, contextual anchors or new supervision can supply calibration; cross-property receiver training should be counted as such rather than silently attributed to an already universal code.

For the denizen, an ordering, a measuring scale and a shared unit are different tools. This offers a concrete vocabulary for donor interfaces: which relations are retained, which calibration is missing, and how much work makes it usable. It does not require discovering a special vector geometry.

### S18. Onboarding must establish a contribution from the new sender

The external WMCP repository is inspected at commit `ca36be0b86eee76425f6aad3f37c634cdbcc8a0f`. Its [Phase 104 implementation](https://github.com/TomekKaszynski/emergent-physics-comm/blob/ca36be0b86eee76425f6aad3f37c634cdbcc8a0f/_phase103_106.py#L429) replaces slot 1 of four senders, freezes the others and one receiver, and trains the new sender on the same mass-comparison task. Evaluation first occurs at loop index 50; all ten [saved curves](https://github.com/TomekKaszynski/emergent-physics-comm/blob/ca36be0b86eee76425f6aad3f37c634cdbcc8a0f/results/phase104_onboarding.json) contain only that observation. There is no step-zero, constant or shuffled-new-sender arm in this function. The base score pools three receivers, while the replacement uses receiver 0. Some loop iterations skip optimizer updates.

The [onboarding demo](https://github.com/TomekKaszynski/emergent-physics-comm/blob/ca36be0b86eee76425f6aad3f37c634cdbcc8a0f/protocol-spec/examples/onboard_new_encoder.py#L81) prints a literal curve in dry-run mode; it does not load those saved results. Its intermediate values therefore cannot fill the missing step-zero control. The demo also uses a different training/evaluation procedure. Root and independent reviewer /root/cache_integrity_review verified these source distinctions. No external script was executed and no model was loaded.

**Our inference:** recovering a fraction of full-system accuracy does not by itself establish that the replacement sender contributes. Remaining senders can carry the task. This is not a finding that the replacement is unused; it identifies the simplest unrun null needed before adopting that interpretation. Observations at index 50 show performance by that check, not the earliest learning time or an exact count of optimizer updates.

**Carry into S14:** evaluate the same receiver and paired items before calibration, with a constant or appropriately shuffled replacement, and after calibration. Establish useful task behavior under the declared interface and resource budget. The contribution may be additional information, improved accessibility of existing information, or a cheaper realization. Removing a message tests dependence on that interface, not unique knowledge; off-distribution ablations need qualification. If the null already meets the endpoint and no other declared benefit changes, that endpoint does not identify acquisition. Establish contribution before

interpreting onboarding speed; count donor computation, calibration, storage and recurring receiver cost separately. Preserve source/task groups for statistics, not independent significance claims from repeatedly sampled pairs. S19 records the distinction between oracle information and usable computation.

The complete tracked tree includes small real-video feature exports, but the required CLIP feature tensor and matching Phase 104 trained receiver checkpoint were not identified. The advertised demo is therefore not a currently eligible zero-model replay from the inspected files. Do not start feature extraction or base training merely to reproduce its headline. The exact missing resources and the contribution-null question are more useful strategy outcomes at this stage.

A complete recursive inspection of the three tracked JSON artifacts `results/phase58b_cross_property.json`, `results/phase95_realvideo.json`, and `results/phase96_clip.json` found metrics/configuration summaries, not per-example message exports with labels. Git blob IDs, respectively: `1e1a0e245d661a04ba7af7c492d5c467abcb646b`, `45fbbe131486283c904637335cb056046fb2827a`, and `a2710dc0b2fd2845fc1dcc2aacb347352fd88564` at the pinned commit above. Thus these three files cannot support S17's proposed alternative-reader test. This is a bounded artifact-eligibility finding, not an absence claim about the entire repository or the information in its trained messages. No tensor was loaded and no new scientific experiment was run.

## S19. Useful computation need not add Shannon information

**Finite decision-theory calculation.** For existing information X, donor message M and target Y, unrestricted Bayes prediction under log loss has risks `H(Y|X)` and `H(Y|X,M)`. Their difference is `I(Y;M|X)`. This assumes an unrestricted predictor knowing the relevant distribution, not an affordable deployed reader. Positive conditional information can leave optimal accuracy unchanged: equally likely posterior probabilities 0.8 and 1.0 have mean 0.9, and both predict the same class. Log loss improves; accuracy stays 0.9.

Conversely, let X contain n independent fair bits and let Y be their parity. A reader allowed to inspect at most n-1 bits cannot exceed half accuracy. A donor supplying parity enables a correct one-bit read, although `I(Y;M|X)=0`: M is already a deterministic function of X. Donor computation must still be counted; this illustrates accessibility, not a total-cost advantage. This analytical example is not a proposed toy benchmark.

Reuse the relevant existing theory. Xu et al., *A Theory of Usable Information under Computational Constraints*, ICLR 2020, [Definitions 1–3, §3 and Appendix F](https://arxiv.org/html/2002.10689), define predictive V-information relative to an allowed predictor family. Preprocessing can increase this usable quantity; ordinary Shannon identities need not all survive. Hewitt et al., *Conditional probing*, 2021, [§2 and Appendix A](https://arxiv.org/html/2109.09234), extend the formulation to condition explicitly on a baseline. Neither gives a free causal acquisition

certificate. A trained probe only approximates the within-family optimization, and our sequential operational/retention requirements remain additional.

**Practical contract:** for the fixed-receiver comparison, report its improvement, then compare with an inexpensive competent alternative under the declared training and inference budget. S2.2 separately permits receiver adaptation with its learning attributed; fixing it is not an acquisition-wide requirement.
These are different claims. Additional information, accessible computation and cheaper realization are all legitimate contributions. Use an information-novelty control only for a novelty claim; use a matched total-cost comparison for an efficiency claim. Do not fit high-dimensional mutual information estimators merely to screen donors.

The distinction also prevents a misleading retention theorem. An optimal reader family that can ignore a new port can retain its old optimum, but a particular learned receiver may deteriorate. Ignoring the port must be executable within the real memory and compute budget; preserving an old weight snapshot is not free. Strategy should discover how to retain usable operations, not assume it from an oracle's optional choice.

## S20. An encoder-based reasoning engine still needs a rule for inference

The frozen encoder can supply observations or conditional predictions. Something must decide which candidate states to consider, which operation to apply next, how to combine donors and when to stop. S8's readout, transition and verifier routes put that computation in different places. The representation itself does not supply an inference algorithm merely by being rich.

**Existing route using pretrained masked models:** Goyal, Dyer and Berg-Kirkpatrick, *Exposing the Implicit Energy Networks behind Masked Language Models via Metropolis–Hastings*, ICLR 2022, [§§2–3 and Appendix J](https://arxiv.org/html/2106.02736), distinguish a declared sequence energy from independently learned masked conditionals. Their sampler uses the conditionals as proposals with an acceptance correction. Repeated full sequence scoring is costly, and their limitations leave optimality of the derived energy unresolved. This is evidence that pretrained encoders can support iterative generation; it does not demonstrate cheap cumulative reasoning.

**Different route requiring new training:** *Energy-Based Transformers are Scalable Learners and Thinkers*, 2025, [§§3–4](https://arxiv.org/html/2507.02092), learns energy functions through unrolled prediction optimization. Its experiments pretrain the proposed models from scratch; this is not an extraction method for arbitrary existing encoders. Inference involves gradients and candidate search, so forward-call counts alone are not a complete compute comparison. Treat this as a constructive next-space design precedent, not evidence that existing embeddings already expose a usable energy landscape.

**Composition obligation:** separately reasonable donor conditionals need not belong to one common joint model. Alternating their updates can still define an

algorithm, but the update schedule becomes part of its meaning. Convergence to a distribution, if established, is distinct from satisfying every donor's conditional predictions. Finite-run order effects alone do not prove global inconsistency; even compatible updates can mix at different rates.

**Score calibration obligation:** independently meaningful rankings do not identify a meaningful sum of scores. On two candidates, let E1=(0,1) and E2=(2,0). Their sum chooses the second; replacing E1 by 10*E1 chooses the first, although neither donor's own ranking changed. A shared utility, calibrated probability/temperature, explicit constraint policy or learned arbitration must supply the missing scale. The same issue reappears when adding each new donor.

This gives three concrete research forks: use existing callable conditionals with a declared inference schedule; learn a reusable operation over frozen features; or co-design a new latent space whose legal updates and readouts are well-defined. They can share donor knowledge while requiring very different training and runtime resources. No route is selected merely because it avoids autoregressive text output. Independent task quality must validate any learned energy or verifier; optimizing its own score is not the quality endpoint.

### S21. Two concrete interfaces and one conditional-preference question

| Candidate | Accessible resource | Missing or confounded element | Strategy disposition |
|---|---|---|---|
| Real-video feature exchange | Two small tracked spring-video exports at S18's pinned repository commit | Static encoder sees one frame, temporal encoder sees 16; object-name sequences match but unique trial IDs/revisions are absent; no competent trained receiver export | Do not run a new supervised probe just because the tensors are small |
| Small protein encoder's masked prediction port | Locally complete ESM2-8M revision `c731040fcd8d73dceaa04b0a8e6329b345b0f5df`, including prediction weights and tokenizer | Predictive value does not identify an inference algorithm, composable updates or a transferred capability | Consider one bounded operational diagnostic of the existing conditional port; no alignment or training |

Independent source/metadata review by /root/cache_integrity_review identified `features[206,8,1024]`, object names and masses in the temporal export, versus `features[206,384]` and object names in the static export. There are 26 objects; matching name sequences do not prove trial pairing when extraction independently skips failures. [Pinned extraction source](https://github.com/TomekKaszynski/emergent-physics-comm/blob/ca36be0b86eee76425f6aad3f37c634cdbcc8a0f/_phase87_phys101.py#L160).

Mass is assigned by object; a trial split would also risk identity memorization.

No tensor was deserialized. This candidate remains a possible control resource, not a selected acquisition experiment.

The second candidate has independent predictive precedent: ProteinGym's [pinned summary](https://github.com/OATML-Marks lab/ProteinGym/blob/144fe22b07dfaeec2b366f2346203a9838a55b4c/benchmarks/DMS_zero_shot/substitutions/Spearman/Summary_performance_DMS_substitutions_Spearman.csv) reports average Spearman 0.226 for its 8M model. This is external benchmark evidence, not a local replication or evidence of reasoning. Its [scoring implementation](https://github.com/OATML-Marks lab/ProteinGym/blob/144fe22b07dfaeec2b366f2346203a9838a55b4c/proteingym/baselines/esm/compute_fitness.py#L240) adds mutation log-odds measured in the reference context; that chosen additive

scorer should not be mistaken for proof that context-dependent updates share an objective. The [original model release](https://github.com/facebookresearch/esm) exposes the masked-prediction interface. No biological application is selected.

**Definition/proposition attempt, before any model run.** Hold a sequence's context fixed except at two sites, each with two possible symbols. At each edge of their four-state rectangle, mask only the updated site and take the within-call logit difference of its destination and origin symbols. Orient the four differences around the rectangle and call their sum C. If all four differences equal differences of one scalar potential, C=0 by telescoping. If every edge differs from such a potential by at most epsilon, then `abs(C) <= 4*epsilon`. Thus `abs(C)/4` is a lower bound on the largest necessary edge correction. It is attained for one isolated rectangle: subtract C/4 from every oriented edge, then the corrected edges sum to zero and integrate to vertex potentials. This does not establish a joint optimum over multiple overlapping rectangles. This is ordinary discrete potential mathematics applied to an operational question: does the same destination have path-independent preference change?

**Locked bounded panel, not yet run:** one 76-residue human ubiquitin reference sequence, four preselected one-based site pairs (10,30), (20,40), (30,50), (40,60); each alternative is A, or G when the reference is already A. No search for a strong witness. Four single-mask inputs per rectangle, repeated unchanged to measure numerical variation; CPU float32, evaluation mode, two CPU threads, no fitting. Pin sequence, tokenizer, checkpoint and implementation. Primary prospective edge tolerance is 0.1 natural-log units (about a 1.105 odds factor); report 0.05/0.2 sensitivity and all raw edges rather than selecting a threshold after seeing the values. This tolerance is an interface approximation choice, not a validated biological-utility threshold.

**Expectation and interpretations:** masked training does not enforce this potential condition, so measurable circulation is plausible but its magnitude is unknown. A bound above tolerance would require explicit reconciliation before treating these edges as one objective. A bound below tolerance would support only these rectangles; neither result chooses a whole reasoning architecture or proves quality. A discrepancy near repeat noise is inconclusive. A substantial raw cycle can still be small relative to the moves, so report edge magnitudes too.

**Moot-making confound:** inconsistent conditioning. Every edge must preserve all other tokens, use the proper corner's other-site symbol and exactly one mask. Do not substitute a double-mask query or compare different token positions. Within-call logit differences avoid probability underflow. This is a local port diagnostic, not a grafting result, inference demonstration or global certificate. The independent second dialogue selected this one diagnostic with those limits. Check shared identical masked inputs across overlapping pairs using the already collected calls. Assert residue/token offsets, legal alternatives and one mask. Reference is the first 76 residues of [UniProt P0CG47](https://rest.uniprot.org/uniprotkb/P0CG47.fasta), retrieved before the run: `MQIFVKTLTGKTITLEVEPSDTIENVKAKIQDKEGIPPDQQRLIFAGKQLEDGRTLSDYNIQKESTLHLVLRLRGG`.

No outcome is yet known at this lock.

**Observed result, independently audited:** the locked CPU run
completed with eight forward calls / 32 input rows, no training, in 60.27 seconds
including startup. [Runner](../experiments/run_conditional_port_probe.py) and
[durable result](../experiments/results/conditional_port_v1/result.json).

| Sites | Oriented circulation (nats) | Isolated minimum worst-edge correction | Mean absolute edge (nats) |
|---|---|---|---|
| 10,30 | 0.1125717 | 0.0281429 | 2.7736793 |
| 20,40 | 0.0038663 | 0.0009666 | 0.4396586 |
| 30,50 | 0.0771118 | 0.0192780 | 2.0189845 |
| 40,60 | 0.0008296 | 0.0002074 | 0.7473513 |

All four isolated corrections are below the primary 0.1 tolerance and both
predeclared 0.05/0.2 sensitivities. Repeated identical inputs and two shared-input
checks agree exactly in this execution. Repeat agreement measures repeatability,
not a bound on systematic floating-point error or cross-platform variation.
There is one checkpoint and one declared sequence; no seed/generalization claim.

**Audited interpretation:** this panel finds no isolated incompatibility exceeding the declared
approximation scale. Exact nonzero circulations are diagnostics, not a negative
verdict over a learned continuous model. Nor does this small local compatibility
check validate a globally consistent or biologically useful objective. Do not
expand the panel to seek a failure. Return to what operation and independent
task objective would make the existing port useful. Practical significance of
the tolerance was not validated. Saved values are within-call logit differences,
not complete destination/reference logits. The timestamped pre-run ledger entry
documents chronology but is not a cryptographically sealed protocol.

**Post-hoc cheapest null, discovered in the independent audit:** ignore the
other edited site's state and use one constant preference per site. For a site's
observed edge values, their midpoint has maximum error half their range. Across
all measured sites, the largest such error is 0.0722242 nats, below the primary
0.1 tolerance. This additive class therefore fits the whole observed panel at
that tolerance. It exceeds the 0.05 sensitivity at site 50. Keeping exactly the
reference-context preferences instead gives maximum error 0.1444484; do not
conflate that narrower null with the best additive class. These are post-hoc
calculations from retained observations, not trained predictors, prospective
held-out controls or evidence of reduced inference cost.

Fresh real Codex CLI audit session `01a09c8d-6c38-7ea2-9abd-cc7b87cd13ae`
independently reconstructed token inputs and potentials, upheld the arithmetic,
and required the additive-null qualification. Verdict relayed by root to audit
board e5a4e16f entry e1021 under the single-writer custody workaround. Audit
synthesis completed; this is separate from the scheduled two-hour approach audit.
**Next question:** what independently scored task requires updating conditional
preferences, and would those updates improve a competent receiver over fixed-
reference scoring, additive scoring and direct donor use at matched cost?

## S22. A bounded screen for useful output complementarity

**Definition before calculation.** For each assay's common finite variant support, replace each donor's scores by its ascending midrank percentile, with tied values receiving their mean rank and endpoints normalized by n-1. The receiver score is the equal average of the two percentiles. Evaluate Spearman correlation with the independent measured assay score, reranking the averaged score with the same tie rule. The rule uses no target labels, but is batch-relative: it needs the declared assay's score distribution. No oracle selects a donor for each item. There is no general theorem that this average must beat either donor.

**Why this question:** S21 did not identify useful updates. Before looking for richer interfaces, ask whether two actual pretrained output ports offer any exploitable complementarity through the simplest declared receiver. This is an eligibility screen for further research, not a demonstration of latent reasoning or cumulative internal acquisition. Nonadditivity in a biological assay alone would not establish a need for iterative reasoning; a fixed nonlinear predictor could capture it. Independent dialogue favored this output screen over a separate epistasis investigation for its closer connection to adding contributors.

**Locked selection before outcome inspection:** ProteinGym v1.3 merged columns `ESM2_8M` and `CARP_600K`, both positive score orientation in the pinned config; four short, accessible assay records: `AMFR_HUMAN_Tsuboyama_2023_4G3O`, `ARGR_ECOLI_Tsuboyama_2023_1AOY`, `BBC1_YEAST_Tsuboyama_2023_1TG0`, and `CBX4_HUMAN_Tsuboyama_2023_2K28`. Selection used reference metadata and archive entry availability/sizes, not assay performance. These are four descriptive units from one assay family, not representative coverage or four independent research replications. Source protocol: [official resources](https://github.com/OATML-Marks lab/ProteinGym/blob/144fe22b07dfaeec2b366f2346203a9838a55b4c/README.md#resources).

The official server supports byte ranges. Archive lengths/ETags checked before fetch: DMS 43,021,128 bytes / `2907348-6329ff6970941`; merged predictions 1,911,045,703 bytes / `71e83e47-633cd6a03f0f6`. Fetch only the central directory, selected local headers and compressed members (about 7 MB), never whole archives. Validate member names, sizes and CRCs; retain hashes and only relevant columns. The first prediction member's header was inspected for eligibility; no outcome calculation or model invocation preceded this lock.

**Primary confound/control:** different variant support or score orientation. Verify variant identity and sequences against the independent assay member; report duplicate/invalid/missing exclusions and use the same joint finite support for both donors and the average. Verify measured scores agree across files. Report each donor's correlation, the fixed average, and differences versus each donor and the retrospectively better donor. The last comparator is diagnostic, not an executable selector trained without labels. No per-variant significance, new tuning, post-hoc donor replacement or inference-cost claim.

**Expectations and decisions:** improved ordering over both individual scores on some assays would motivate examining the complementary distinctions there. Matching or losing to the better donor does not justify a richer interface for this pair/rule yet. Mixed effects motivate explicit task/calibration requirements;

they do not authorize tuning these same four outcomes into a prospective result. No direction depends on a claimed improvement before the result exists. Two independent dialogue rounds selected this one bounded screen, with no model loading or training. It cannot establish sequential retention, internal transfer, biological intervention benefit or generalization beyond the panel.

**Observed, independently audited and numerically corrected:** the screen completed in 23.86 seconds, including bounded retrieval, with 8,610 jointly scored variants and no exclusions or identity/endpoint mismatches. No model calls or training. The fixed average lost to the retrospectively better donor on all four assays.

| Assay | First donor Spearman | Second donor Spearman | Fixed average | Difference from better donor |
|---|---|---|---|---|
| AMFR | -0.208771 | -0.194402 | -0.205586 | -0.011184 |
| ARGR | 0.331586 | 0.266615 | 0.313539 | -0.018047 |
| BBC1 | 0.331119 | 0.113237 | 0.238012 | -0.093106 |
| CBX4 | -0.271018 | -0.320185 | -0.301905 | -0.030887 |

Donor order is the locked column order above. Negative signs were investigated after calculation: individual values agree to reported precision with the [official pinned per-assay table](https://github.com/OATML-Markslab/ProteinGym/blob/144fe22b07dfaeec2b366f2346203a9838a55b4c/benchmarks/DMS_zero_shot/substitutions/Spearman/DMS_substitutions_Spearman_DMS_level.csv). The official metric implementation uses signed Spearman, not absolute correlation. Do not flip a donor after seeing these test outcomes. Broad average benchmark performance did not establish competent prediction on each chosen assay.

This pair and fixed rule do not supply a positive gate toward richer grafting here. The result does not exclude complementarity under another justified rule, other donors or other tasks; it gives no bound on latent information. Retained [subset data and provenance](../experiments/results/cached_donor_screen_v1/result.json) and [runner](../experiments/run_cached_donor_screen.py) make this bounded screen reproducible without any donor runtime. Its next consequence is to require task-specific competence and a reason to expect complementary value before selecting an expensive interface, not to tune this panel until it wins.

Fresh real Codex CLI audit `01a09c9c-3c7b-7eb3-b9bd-327d54eb9bb5`, relayed as audit e5a4e16f e1022, upheld this bounded negative and required a numerical correction. Floating-point percentile normalization split mathematical ties in the summed ranks. Integer doubled-midrank sums preserve the specified ordering; the largest correlation change is 0.00001343, with no verdict change. Corrected offline from retained CSVs, then independently checked with SciPy. Constant columns are explicitly undefined rather than assigned zero correlation or a loss. Original source/result are preserved in commit `0f61942`; current result carries original hashes and values. No new network or model calls were needed.

The audit validates the retained subsets and calculations, not independent authentication of discarded complete archive members. Source-support and endpoint agreement are the recorded runner's checks, with bounded retrieval, CRCs and hashes. Preregistration hashes support local chronology, not an independently timestamped seal. Byte-preserving Git attributes protect these

hash-bound inputs, results and runners from platform newline conversion.
Close this screen. Its failure neither establishes nor excludes exploitable
complementarity, and is not a reason to tune weights or swap donors on this panel.

### S23. Pairwise compatibility does not establish a composable growing system

**Definition/proposition attempt.** Suppose a donor port exports constraints over shared, explicitly identified binary variables. Three ports assert A=B, B=C, and A!=C respectively. Every pair of ports has a satisfying assignment; all three together do not. Thus testing each incoming donor against each existing donor separately cannot certify that their combined requirements remain realizable. For any cycle length, equalities along a path plus one inequality between its endpoints give the same obstruction: every proper subset is satisfiable. This is ordinary constraint mathematics, not a finding about any real model. It identifies a missing requirement in a naive pairwise acquisition protocol.

The probabilistic version is stronger: each equality/inequality port places uniform mass on its two satisfying pairs. All shared singleton marginals agree, yet the three pair laws have no common joint. Every assignment violates at least one relation, so any candidate joint has summed violation probabilities at least one. At least one prescribed pair law must therefore change by TV at least 1/3. This gives the counterexample tolerance meaning without an exact-only verdict.

The denizen needs to know when individually usable imported rules can be obeyed together. S13 already separates inconsistent requirements from weight interference; this example adds that the inconsistency may only become visible at joint use. Agreement on familiar tasks or two-donor tests can miss it. A language for latent interfaces should identify their overlapping distinctions and the scope of each rule, rather than treating every successful pairwise chart as a universal map.

**Conditional constructive alternative.** For finite variables, organize ports as a tree of clusters, with one normalized distribution per cluster. Require agreement on neighboring overlap marginals and the running-intersection property: every variable's clusters form a connected subtree. A joint distribution can then be constructed by sampling the root cluster, followed by each child's private variables conditional on the already sampled overlap. Marginal agreement ensures the child's overlap has the required law; the tree property ensures no earlier assignment outside that overlap is silently changed. Induction preserves every cluster marginal. At a zero-probability overlap, the conditional can be chosen arbitrarily because that event is never reached under the exact joint.

**Existence is not identification.** Let AB and BC both be uniform independent binary pairs. Their laws permit A=C with B independent, A!=C with B independent, or complete independence. The construction chooses one Markov completion; it does not infer which world produced the marginals. To answer a new joint question such as whether A=C, justify conditional independence, collect coupling evidence, or report the range over admissible completions. Combining separately competent ports does not automatically supply knowledge of their cross-domain interaction.

This is an existence construction under strong explicit assumptions, not a cheap

inference result or a proposed architecture. Representing/calibrating the overlap law can be expensive. Learned ports may not expose shared variables, their confidence scores may not be calibrated distributions, and constraints may be inconsistent. Approximate or partial agreement needs its own reachable-support and error accounting; do not import the exact construction as an approximate certificate. S5's conditional-kernel bounds apply only after those conditions are established.

**Strategy consequence:** distinguish two ambitions. An ensemble may use an explicit arbitration or update schedule without representing one consistent world model. A composable shared-state system needs additional compatibility structure or a rule for resolving joint contradictions. Neither is automatically the correct destination. Before measuring N-to-N alignment, ask what overlap information and joint-use obligations the intended system actually exposes. No compute is proposed for this analytical counterexample.

Independent dialogue with /root/cache_integrity_review supplied the identification qualification and approximate triangle bound. The decision-changing obligation is that promised joint queries must be identified or adequately tested, not just that pairwise adapters function. A next space might expose overlap identity, scope and unresolved coupling; it need not impose one global world model on all donors. Do not build a generic consistency harness without an actual interface that requires it.

### S24. One worked acquisition episode: adding structure to a persistent page

**Purpose and definition.** This is an on-paper account of where joint-use knowledge comes from, not an implementation, selected application, or model result. Let a persistent page representation retain source identity, recognized tokens and their locations. Acquisition extends the operations or relations available over that same page, before later questions arrive. Retention concerns declared earlier uses, while correction of erroneous tokens follows an explicit policy. The broader project remains native latent mathematics and cumulative model contributions; this concrete episode exposes a simple serious baseline.

**Actual page.** The Table Transformer repository's [illustration](https://user-images.githubusercontent.com/10793386/139559159-cd23c972-8731-48ed-91df-f3f27e9f4d79.jpg) shows Table 4 on page 6 of Popoola et al., [BMC Oral Health 17:8](https://link.springer.com/article/10.1186/s12903-016-0236-6). We visually inspected that released illustration, not a new model output. A later literal table query is: among rows under socioeconomic status, which have a printed numeric P value above 0.9? The displayed middle category has 0.95, the low category 0.68, and the high category a dash; the answer is the middle category only. This is a transcription/query example, not a medical or statistical interpretation of the article.

| Episode | Distinction or operation | Its source and learning attribution |
|---|---|---|
| Initial receiver | Filter typed records, follow declared relations, compare numbers, count | Existing explicit executor; it must be checked on correctly supplied records, not assumed competent because it is code |

| | | |
|---|---|---|
| First donor acquisition | Word identities, numeric strings, locations and reading order | A pretrained OCR interface; alternatively direct PDF text extraction if the deployment input permits it |
| Second donor acquisition | Table rows, columns, spanning cells and header regions | Pretrained structure model consumes the page/table image; no final query answer is supplied to it |
| Cross-donor coupling | Which word belongs to which cell; which row/column the cell belongs to | Shared page/crop coordinates plus explicit postprocessing rules, not a relation magically inferred from matching latent vectors |
| Later joint question | Scope selection, numeric comparison and output | The existing executor uses the acquired text and structure; any new scope rule or schema conversion must be counted as receiver work |
| Retained uses | Locate earlier words and read isolated values | Preserve token identity/provenance through structural additions, and test read behavior; copying old records alone is not evidence of all retention |

Removing final-answer supervision does not remove this example's identifying relationships: the declared structural interpretation and executor determine the answer. But that is conditional on correct text, correct structure and a valid interpretation of the section header. Removing the structure leaves an open empirical question, not a guaranteed failure: simple coordinate grouping may recover the same relations. Removing text leaves boxes without the required labels/values unless some other permitted input supplies them.

**Available component interfaces, inspected without loading weights.**

[Tesseract's documented TSV/hOCR output](https://tesseract-ocr.github.io/tessdoc/Command-Line-Usage.html) supplies words, locations, reading-order fields and confidence; ordinary TSV is not a distribution over alternative readings. The English fast trained-data file is exposed at revision `87416418657359cb625c412a48b6e1d6d41c29bd` (4,113,088 bytes). This establishes availability, not competence on the page.

At Table Transformer code revision `16d124f616109746b7785f03085100f1f6247575`, [recognize](https://github.com/microsoft/table-transformer/blob/16d124f616109746b7785f03085100f1f6247575/src/inference.py#L756) passes the image to the structure model and receives OCR/PDF tokens separately. The pipeline does not itself perform OCR. Model output supplies structural boxes; fixed rules intersect rows/columns, resolve spans and assign each token to a cell by geometric overlap. Header conventions and conflict removal are also explicit code. Independent source inspection verified this division of labor. A public structure checkpoint exists at `bsmock/TATR-v1.1-All` revision `30e6112ea20d72cc9fb8f443e34ca119d497cfe6`; no weights were downloaded or executed. These are learned structural predictions plus an existing binding procedure, not demonstrated transplantation of that procedure.

**A port choice that has concrete consequences.** The inspected pipeline's cell records retain locations, row/column membership, spans and header flags. HTML and CSV omit some of those fields; CSV additionally flattens headers and repeats spanning-cell text. The pipeline does not expose a joint distribution over alternative assignments. Omission of a field does not alone prove that a later query becomes impossible: it may be reconstructible. Compare actual retained distinctions and queries before declaring an interface inadequate.

The strong structured alternative can preserve multiple readings, alternative parses and coupled assignment constraints. It is not limited to one hard table or independent confidence scores. Such a schema and inference procedure would require work and cost accounting; do not assume they come free. A richer learned port earns investigation if a specific useful distinction or efficient operation is lost by a comparably funded explicit interface, not because explicit ports are intrinsically incapable of uncertainty.

**Growth and access boundaries.** Keeping callable donors supports new pages; keeping this page's annotations only supports later questions about this page. The question arrives after representation acquisition, so a cached answer to it is not the proposed persistent artifact. The source HTML/annotations are for inspection and evaluation; if they are available to the deployed receiver, direct use is the first comparator. An image-only contract must be stated rather than silently hiding a cheaper available source. Later donor updates may change crop coordinates, tokenization or scope conventions; those changes create actual repair obligations even if neither backbone is trained again.

**Decision from the episode.** It is possible to assign the joint-use relations to concrete resources without postulating one universal latent space. Whether these particular donors add value on this page is unmeasured. The next scientific question is which part of a growing interface must change when a donor adds a new distinction, and what earlier operations can remain meaningful. Token/cell identity, scope, correction and continuation are useful vocabulary here; pixel geometry and fixed table rules remain ordinary scaffolding. This episode is not a demonstration of new mathematics or latent-model structure. No OCR, table pipeline, acquisition training, benchmark or uncertainty system is queued.

**Repair made concrete, without a wrapper project.** In the inspected [`objects_to_crops`](https://github.com/microsoft/table-transformer/blob/16d124f616109746b7785f03085100f1f6247575/src/inference.py#L252)
path, the crop's token list contains the original token dictionaries and their boxes are rewritten in place into crop coordinates. Rotation rewrites them again. Crop records retain image and tokens, not an explicit inverse transform; `extract` returns crop-local outputs. Multiple crops can share those dictionaries. Independent review and root code reading confirm this source-level dataflow; its occurrence on the illustrated page was not run. Crop-local coordinates can be a legitimate API convention. The path simply does not, without caller work, satisfy our proposed immutable page-coordinate contract.

Apply the existing S5/S13 distinctions rather than inventing another general theorem: known coordinate conventions need deterministic translation and provenance; splitting/merging tokens must be judged by the old reads it preserves; new semantic relations need their actual evidence or learning source; changed facts need a correction policy. A merged token can preserve old reads if it retains constituent identities and locations. Keeping page records and view transforms addresses this wrapper obligation without changing learned spaces. This is a prerequisite correction, not the next scientific artifact.

The remaining learned-interface question is specific: which relation needed by a later query is inadequately supplied by OCR plus a declared cheap grouping rule, yet supplied by the frozen structure port? The illustrated page provides no measured such contrast. Its section membership may be recoverable by simple grouping; a schema field's presence or omission alone does not resolve that. Do not run another convenience-selected page to obtain an attractive failure. An eligible test needs the relation, its independent reference, the donor field that supplies it, and comparable receiver inputs. Only then can intervention separate a useful learned contribution from wrapper repair or ordinary grouping.

**Second dialogue: choose the useful revision before the intervention.** A proposed cell-crop replacement test was not selected: independent crop processing, annotated cell identity and an explicit executor would supply most of its locality and composition laws. It could validate an interface without discovering learned structure. The sharper question is which useful later decision requires revising an earlier interpretation using context supplied by a new donor, and which old uses should survive. Header membership is an example only; this page has not established a discriminating ambiguity or donor competence. Choose the actual decision and independent reference before varying contextual evidence. A typed record system that economically supports such revision is a valid cumulative acquisition endpoint. It leaves the broader mathematical question open rather than disqualifying the direction. No new experiment follows from this dialogue.

**Worked identification problem after two fresh design-dialogue rounds.** A separate hypothetical purchasing case makes the missing evidence precise. Assume independent groups A/B, whole-carton ordering, and an authoritative correction replacing the old size only in its stated scope. Both groups initially use 12 items/carton. The acquired port reports `items/carton = 10` but omits scope. Two exhaustive interpretations are A-only, giving sizes (10,12), and A+B, giving (10,10). For a request of q items from group g, the stipulated task is `ceil(q/size_g)`.

| Later use | Before | A-only correction | A+B correction |
|---|---|---|---|
| A, 30 items | 3 | 3 | 3 |
| B, 30 items | 3 | 3 | 3 |
| A, 36 items | 3 | 4 | 4 |
| B, 36 items | 3 | 3 | 4 |

A's 30-item calculation depends on size even though this particular correction leaves its answer unchanged. Keep three things distinct: dependence on a variable, applicability of this correction, and realized change in a chosen answer. A map of observed answer changes alone cannot identify the first two.

Within these stipulated noiseless hypotheses, one reliable distinction resolves the ambiguity: does the correction cover B? An authoritative statement, a clear scope boundary under declared conventions, or a trusted B-size observation can supply it. The B/30 answer cannot. A trusted B/36 answer can, but then it becomes acquisition evidence and cannot also demonstrate an unqueried consequence. Asking an uncertain receiver does not make its response authoritative. Until the distinction is supplied, retain both alternatives. This instantiates S1/S23's

existing information argument; a typed scope field is a sufficient repair here.

**Permissions and scientific bridge.** Acquisition may use scope-bearing evidence and declared calibration labels, with S2.2's fixed procedure and budget. Withhold later answer labels and manually enumerated affected-use lists; then test fresh quantities and compositions after freezing acquisition. Charge continuing donor calls and give structured/direct-forwarding alternatives matching information. If an explicit executor supplies every dependency and consequence, success is useful integration. A learned operational claim instead requires a relation inferred from donor/receiver behavior to predict later response changes and preservation before those responses are examined. Controlled changes to the scope evidence should selectively alter those predictions, across new cases, without caller-installed dependency routing supplying the claimed model law.

The new decision is where to place identifying evidence and what to reserve for evaluation. Dependency graphs and program slicing are established scaffolding; renaming them would not advance the native-mathematics mission. No purchasing page, model, new benchmark, or compute run is selected. The bounded empirical question is whether a useful learned dependency can be discovered economically and predict fresh uses, alongside the valid typed-integration alternative.

**Decision-bearing revision contract: typed route retained.** The second periodic review asked which acquisition decision a learned revision predictor would improve. For the purchasing stipulation, the answer is none:

- Later decision: how many whole cartons to order for a fresh quantity in A or B.
- Revision operation: replace the external size record for the authoritative scope. Do not edit model weights, hidden states, or an input prompt implicitly.
- Evidence: the corrected value, its unit, affected group identities and the authority to supersede the old value. These are stipulated inputs here, not outputs demonstrated by the table model or a real purchasing document.
- Receiving interface: `size[group]` read by the already specified ceiling executor. This is the existing *on-paper* interface, not an installed receiver or a verified learned model. Acquisition changes records; the executor stays.
- Retention: under A-only correction, every valid B quantity uses its old size; A quantities use the new size even where the resulting integer stays fixed. Preserve provenance of the replaced record separately from current truth.
- Acquisition decision: accept the authorized, identified correction; if scope remains ambiguous, retain both possibilities or obtain identifying evidence. A prediction of an unrelated learned receiver's answer changes none of this.

Under these assumptions, explicit scoped import supplies the complete useful operation. No implementation or model experiment is needed to establish that conditional conclusion. No arbitrary-scope, unreliable-source or economically superior deployment claim follows. In particular, the actual table source does not export an authoritative `applies_to_B` field. Inferring one from boxes would be an additional semantic operation requiring its own evidence.

An independent approach check identified the strongest remaining role for learned-response prediction: predicting when a *producer's interpretation* is

unreliable could change accept-versus-recheck decisions before typed import. That would require a real independently scoped correction, a callable port that attempts that interpretation, and an available additional observation whose cost can be compared with prediction. The selected illustration supplies none of this contrast. Replacing its executor with an unverified learned receiver would only manufacture a harder problem. Close this purchasing candidate as an on-paper success for scoped import. Retain typed import as the leading route for this contract; do not generalize it to all capability acquisition.

The transferable boundary is operational: a learned map earns a job when it changes an available choice of acquisition, intervention or reuse at acceptable error and effort. A map that only forecasts behavior can still inform the broader native-mathematics program, but that alone does not advance cumulative acquisition. The current contract's identity, revision and preservation laws are supplied by its interface; they are not discovered properties of a learned latent space.

**Existing causal-abstraction bridge.** The historical [intensional-descent note](closed/INTENSIONAL_DESCENT.md) already names this foundation. [Geiger et al., Causal Abstractions of Neural Networks, 2021](https://papers.nips.cc/paper/2021/file/4f5c422f4d49a5a807eda27434231040-Paper.pdf), §§3–5, proposes a symbolic model, searches alignments, then swaps source/base activations. The neural model computes consequences; the symbolic model supplies test targets. MQNLI candidate structure comes from its generator, with task and phrase-relation fine-tuning before analysis. Interchange targets do not train that network. The empirical scope is sampled examples and alignments, with an exhaustive pair/clique procedure unsuitable for a small probe. This is causal-abstraction testing, not untouched-pretraining or cumulative-grafting evidence.

Our remaining discovery question is which task-useful revision rule predicts the learned system's consequences, including failures, before we train it to obey that rule. A proposed symbolic rule can be an evaluation hypothesis without supplying the model's computation. If intervention targets teach it, attribute that learning. The possible contribution is discovering and using an informative operational structure while satisfying acquisition and retention obligations.

## S25. Revision: importing facts and acquiring their consequences

Lifelong knowledge editing is substantive prior art for the user's growing-knowledge ambition. It should not be omitted because its exports can be text. The following source readings are not replications or a selected editing project.

**Corrected-target acquisition.** [MEMOIR, v4](https://arxiv.org/html/2506.07899v4), §3, Appendix A.2/A.4.3 and Table 14, learns a fixed-size residual FFN matrix from prompt–target pairs while storing a growing database of activation masks. Frozen upstream features determine masks; nearest-mask Hamming matching gates inference. Thus fixed parameter count does not mean fixed total storage or lookup burden. The sequential procedure uses fixed per-model training settings and prefix augmentation. Paraphrase tests differ from its Temporal test of another continuation for the same entity prefix. On the filtered 100-edit RippleEdits POPULAR subset, reported reliability is .98, logical generalization .20 and

specificity .59. These endpoints separate remembering targets from propagating their consequences. This is a useful cumulative-learning baseline, not a donor-computation transfer demonstration. Independent reviewer read methods and experiments; root cross-checked the source table and retrieval equation.

**A concrete revision contract already exists.**
[Cohen et al., RippleEdits, TACL 2024](https://aclanthology.org/2024.tacl-1.16.pdf), §§3–5, tests logical consequences, two-hop composition, aliases, preservation of other objects and relation specificity. The benchmark uses Wikidata plus manually specified dependency rules and language templates. Its filtering conditions evaluation on successful edits and prerequisite query competence, so conditional scores and eligible coverage must be distinguished. A direct in-context edit is an explicit comparator. The source's dependency rule and counterfactual convention are part of the target semantics; type-correct questions alone do not validate every entailment. We should audit the selected rule before calling its violation a failure of reasoning. A stipulated convention can be coherent; its prompt and correction policy must convey that convention. This supplies a task language, not an automatic reason to run its full benchmark or import its results as ours.

**Positive sequence evidence with conditional mathematics.**
[Ma et al., StableEdit, v1](https://arxiv.org/html/2605.11836v1), §§2–5, Appendix A/B.4, studies repeated labeled edits using running gradient statistics, whitening and ridge-regression updates. It reports long-sequence editing and general-task retention tests. The analysis assumes smooth bounded gradients, nondegenerate covariance, trackable drift and moment bounds under a working statistical model. Theorem 3.8(c) retains a cross-step conditional-direction correlation term; near-orthogonality is qualified for unrelated edits, not every possible sequence. Whitening also incurs width-dependent matrix work. These are relevant stabilization mechanisms and reported behavioral results, not a theorem of arbitrary capability retention or heterogeneous grafting. No full proof audit, implementation validation or replication has been performed here.

**Our analytical caution and synthesis.** Orthogonal parameter updates alone do not preserve an old read: for `f(w)=w1+w2`, updates `(1,0)` and `(0,1)` are orthogonal but both change f. This is a counterexample to that bare implication, not to the papers' algorithms or experimental results. Geometric stability can be scaffolding; the operational question is which actual reads and subsequent revisions survive.

Answer import is a valid acquisition branch. A stronger branch acquires a useful dependency or operation that makes new consequences computable. Neither can promise all old answers remain fixed when a correction changes their premises; reuse the S7/S13 correction policy. The decision-changing question is whether the donor supplies a new answer, an already usable relation, or evidence from which the integration procedure must learn that relation. Keep the source of that learning explicit before attributing a new reasoning capability to the growing space.

## S26. Locked bounded question: autonomous conditional continuation

**Definition/proposition attempt, before compute.** On a reference construct x,

conceal sites i<j. Let M(x with i,j masked) supply independent amino-acid argmax predictions a,b. The autonomous move writes a at i and queries j again; the caller supplies this schedule, and the pretrained model supplies each conditional. The empirical hypothesis is that the generated intermediate improves both-site and second-site reference recovery enough to pursue this direct callable procedure. There is no theorem that conditioning on a model's own guess improves accuracy. The useful decision is whether to investigate this existing callable continuation before paying to learn a receiving interface. This is self-composition of one encoder, not cross-model acquisition, biological fitness or a reasoning result. **So what:** can this model use its first guess to improve its second?

Two fresh real CLI direction rounds revised and adopted this single diagnostic; the competing exporter-emulation proposal lacked a concrete reason to approximate this inexpensive port. No result here decides whether to retain donors generally. The expected failure modes are incorrect intermediate proposals, an insensitive continuation, or order dependence. An oracle intermediate is diagnostic only and is not a guaranteed upper bound for a misspecified model.

**Locked support and permissions.** Reverse declared substitutions in every row of S22's four retained CSVs, checking destination residues, indexing, and agreement on one reference per assay. The source inspection passed all 8,610 rows: construct lengths 47, 69, 64 and 50. They are assay reference constructs, not independently verified natural or pretraining-held-out sequences. Use no assay scores or cached prediction scores. For length L, choose the eight distinct one-based positions `floor(k*(L+1)/9)`, k=1..8; pair consecutive selected positions. Thus four nonoverlapping pairs per construct, 16 pairs total, selected without outcomes or residue-dependent filtering. No replacement pairs, expansion or tuning after runs. Only visible residues, mask locations and model predictions enter autonomous inputs. Concealed reference tokens enter scoring and isolated oracle arms.

**Arms and cheapest confound.** Use the already cached S21 snapshot, revision `c731040fcd8d73dceaa04b0a8e6329b345b0f5df`, CPU float32/eager, two threads, eval mode, no training or downloads. Restrict choices to the fixed 20 standard amino acids in alphabetic order; ties take the first. Seven batches of 16 rows:

1. Doubly masked independent predictions at both positions.
2. Identical-input repeat: report probability noise and argmax agreement.
3. Increasing-position autonomous continuation, inserting its own prediction.
4. Decreasing-position autonomous continuation, locked order sensitivity.
5. Increasing-position oracle continuation, inserting the true first residue.
6. Decreasing-position oracle continuation, isolated diagnostic.
7. Increasing-position content control: cycle the initial first-site predictions so pair k receives pair (k+1) mod 4 within each construct; insert at first sites.

The installed `modeling_esm.py` lines 265-272 rescales embeddings according to observed mask fraction; snapshot `token_dropout=true`. The content control keeps one mask and the within-construct marginal of inserted predictions, addressing mask-count scaling and generic unmasking. Record coincident own/control insertions; compare **second-site** recovery for attribution, not both-site accuracy penalized

by deliberately misplaced first guesses. This is a targeted control, not a proof against every presentation effect. Do not change the model's normalization.

The cheapest serious equal-call scheduling alternative is confidence-first: choose which position to fill first using the larger top-two probability margin from the initial call, ties increasing-position. Assemble its trajectory from the measured two orders; no extra forwards and no reference-based winner selection. Report actual experimental cost separately from the policy's two-call deployment cost. No efficiency advantage is established by comparing to the unchanged-input repeat.

**Locked approximate continuation criterion.** Primary always means increasing-position autonomous continuation; confidence-first never replaces it. Second-site comparisons use j for increasing order, i for reverse, and whichever site the confidence-first policy leaves second against its corresponding initial prediction. All must hold: parent-macro gain
of at least .10 in both-site recovery and .10 in second-site recovery versus independent completion; positive both-site gain on at least two parents and none negative; reverse-order aggregate both-site change at least -.0625; primary second-site gain versus the equal-mask content control at least .10. These are resource-allocation thresholds for a conspicuous local signal, not statistical reliability or theorem gates. Report per-parent numerators, corrected/spoiled predictions, probabilities, oracle and confidence-first results. Probability improvement cannot rescue failed recovery criteria. Repeat argmax disagreement, nonfinite outputs, malformed support or timeout makes the probe inconclusive.

Cap wall execution at 180 seconds including startup with an enforceable deadline and per-batch checkpoints. Seven model forwards / 112 rows maximum; no GPU. Timeout is incomplete, not a negative result; do not extend or silently rerun. A passing result licenses only local autonomous continuation on this support. Oracle-only improvement suggests proposal quality as an obstacle; no gain closes this procedure on this panel, not the encoder-reasoning mission. Four parent clusters permit descriptive spread, not pair-level significance or generalization. The preserved mathematical question is when a learned operation's output remains usable by another operation. No discovered latent-space law is claimed from the caller-defined token substitution or scheduling alone.

**Observed result; independently audited (e1044-e1045).** The single run completed in 10.1455 seconds: seven CPU forwards, 112 rows, all 16 cases completed in each measured arm, no training/GPU. Identical-input probability drift was zero. Primary and independent both-site recovery were 0/16; primary second-site recovery was 2/16 versus independent 2/16 and cyclic control 3/16. Reverse and confidence-first also recovered 0/16 pairs. Oracle second-site recovery was 3/16 in increasing order and 1/16 in reverse, versus corresponding independent baselines 2/16 and 1/16. These are fixed-position recoveries, not open-ended termination or biological quality scores. Root manually checked all 16 decoded residue pairs against the recorded targets. A fresh real CLI audit independently reproduced every count, source reconstruction and custody/code-path check. Reverse and confidence-first each correct one and spoil one prediction. Reported

wall time starts in main, excluding interpreter startup; the external supervised 180-second wait returned exit 0. The audit prose mistakenly says 100.15 seconds; the raw result is 10.145497100020293. Its receipt and correction are in the ledger.

The registered continuation criterion fails; close this procedure on this panel. A post-run diagnostic explains an important limit: the initial increasing-order first guess was correct on only 1/16 cases. Since this policy never revises that guess, its both-site recovery cannot exceed 1/16 even with a perfect second step. Thus the locked .10 gain threshold was unattainable with these proposals. This is evidence of weak proposals in the chosen setting, not a strong exclusion of composition given competent inputs. Do not lower the threshold, change pairs, claim absence of conditional structure, or infer that a learned exporter helps. Raw probabilities, parent counts, source/runner/snapshot hashes and timings are in [the result](../experiments/results/encoder_continuation_v1/result.json).

### S27. Connected refresh closes the stipulated navigation episode

**Third periodic review and second dialogue, 2026-09-14.** The proposed traversability-then-energy episode closes through full-refresh typed acquisition, conditional on adequate ports. Both contributions must address the same directed edges, vehicle and conditions. Traversability needs feasible/infeasible/unknown semantics. An additive-cost planner can filter edges and minimize supplied energy; history-, payload- or battery-dependent costs require appropriate state or a restricted contract. The old shortest-feasible-route operation remains callable; an energy-aware choice may legitimately differ. No installed donor, run, general savings claim or learned continuation mechanism is asserted.

Three changes remain distinct. A physical change can alter a property's value. A viewpoint change can alter visibility, confidence or correspondence without changing the property. Obsolete model inputs can require recomputation even in a static world. A new start position changes the route; it need not change edge costs. Full requery uses current available evidence, not knowledge of unseen change.

The reusable recipe registers identified contributions, supplies inputs, refreshes ports and invokes established consumers. Meaning, units, calibration, coverage, correspondence and any new consumption rule remain donor-specific teaching or engineering. A shared schema does not establish transfer of their interpretation. Caller-installed invalidation rules make selective refresh ordinary caching; without an actual recurring burden and error consequences, no savings comparison selects learning them. Do not extend this episode into another benchmark or cache study. Its residue is to separate contribution acquisition, evidence revision and consumer recomputation, then name which obligations cease recurring on addition.

The second fresh dialogue accepts root's objection and recommends reusing learned consumer operations across acquisitions instead. This is a constructive use of S2.2, grounded in S8's positive precedents, not a new empirical result. It leaves full-refresh connected access eligible and charges all new interpretation learning.

### S28. Reusing interpretation across successive contributors

**Constructive target adopted after three dialogue rounds, 2026-09-14.** Fix

one prediction task, label semantics, identified labeled support and an already learned consumer F. Add two contributors using the same recipe: `D0 -> D0+D1 -> D0+D1+D2`. The second addition tests repetition, not scalability. At each stage retain the callable donors, support encodings, declared calibration, receiver changes and established single/joint-use configurations. Evaluate useful added contribution on fresh inputs and retention of earlier uses. This is a strategy contract, not a selected architecture, benchmark or run.

Shared support can reuse labels when the same identified examples and target meaning remain valid. New donor encodings and their interpretation still cost work. Missing correspondence, new granularity or new task semantics may require new teaching. A fresh simple reader gets the same support and all accumulated views; it is not artificially limited to the newest donor. Compare initial consumer learning, per-addition encoding/calibration/repair, and per-query work separately. F may infer a task-specific rule during each forward pass: that is valid reusable inference, but it is not no learning or free recurring computation.

The persistent acquisition state need not be a changed backbone. A registered contributor, its calibrated interface and retained support can enable fresh uses. Preserving an old callable configuration and maintaining quality of the expanded configuration are different obligations. Old predictions may legitimately improve; keeping files alone or insisting on identical answers is not the quality test.
This first contract adds evidence under an existing operation. New operations remain a distinct branch requiring their own semantics and consumption learning.

**Selected source-detail question, now inspected:** when another view arrives, what can stay prepared, and what is rebuilt for each query? Root and an independent reader revisited SIMPLE's method and Appendices A–D; the source report is S8. The following dependency analysis is our inference from that stated architecture, not a measured cache implementation or timing result.

| Object | Reuse conditional on unchanged dependencies | What can require renewed work |
|---|---|---|
| Raw reference inputs, IDs and labels | Same examples and label meaning; input available to new donor | New modality inputs, missing original references, changed granularity or semantics |
| Per-donor support encodings and fixed preprocessing | Pinned donor, input, projection and support statistics | Using the new donor on support examples requires its own aligned features; absent features remain masked with usefulness unestablished. Encoder changes or recalibration invalidate affected values |
| Feature-level within-view processing | Fixed parameters and that view's inputs | A new view needs its own processing; adapter changes can affect previously processed views |
| Cross-view support representation | Same view set, masks, indexing, values and receiving parameters | New evidence enters cross-view attention and normalized aggregation, so old joint representations cannot simply be assumed valid |
| Sample-level contextual outputs | Same complete permitted context and parameters | Joint support/query attention allows query-dependent support processing; the source establishes no reusable final support summary or independent-query equivalence |
| Calibrated reader/configuration | Its declared parameters and support remain valid | SIMPLE-A can change calibration/readout objects; the exact per-view/shared update scope is not fully resolved by prose alone |

This is not a claim that every value necessarily changes, that all partial caching is impossible, or that the published implementation realizes these cache boundaries. Fixed earlier-stage computations can be reusable even when a later joint state is not. The source's description licenses dependencies, not an exact incremental API. The actual cost advantage and optimal reuse boundary still require measurements.

**Acquisition-evidence choice.** Backfilling a new donor on retained support inputs is one concrete way to provide its relationship to the task without acquiring new target labels. It needs those inputs and donor calls. If they are unavailable, possible alternatives include new labeled calibration examples, paired unlabeled bridges or retained source access with suitable prior structure; adequacy is not automatic. Missing-view support is not evidence that a view absent from every labeled support row will become useful. Do not promote full backfill to a universal necessity or claim that saved old embeddings substitute for arbitrary original inputs. Existing S1/S10/S23 already contain the identification cautions.

**Investment implication.** This precedent offers a reusable inference procedure, not demonstrated permanent compilation of each task's inference. Initial synthetic pretraining, per-addition support preparation and recurring contextual computation are distinct investments. Its reported downstream advantage does not determine how many acquisitions or queries amortize initial training. Unknown absolute costs need not block the strategy question: specify which retained acquisition evidence and reusable preparation a future method would require, then compare against fresh simple fitting on that same evidence. No implementation or new compute follows.

**S28.1 — worked baseline identity before allocating initial training.** The fresh-reader reference must not imply that simple methods necessarily restart all optimization. For aligned support rows, let X be retained old features, Z a new contributor's features, Y fixed targets and lambda>0 a fixed ridge penalty. Put A=X^T X+lambda I, B=X^T Y, C=X^T Z, D=Z^T Z+lambda I and H=Z^T Y. The expanded ridge fit solves the block normal equations. With S=D-C^T A^{-1} C, its exact coefficients are

`beta_new = S^{-1}(H-C^T A^{-1}B)`,

`beta_old_updated = A^{-1}B - A^{-1}C*beta_new`.

This is an existing Schur-complement identity, not native latent mathematics or a numerical result. The previous factorization and solution can be reused; this primal route also needs the new normal-equation terms. A practical solve uses factors rather than explicit inverses. Lambda>0 makes the full Gram system and its Schur complement positive definite. Changing regularization or preprocessing changes the problem and reusable objects. Root and an independent reader checked the algebra. Reuse does not establish a substantial speedup: dimensions, conditioning, retained factors and implementation determine its cost.

There is a distinct dual route for the same objective. With retained support Gram K_old=X X^T, form `K_total=K_old+Z Z^T` and solve `alpha=(K_total+lambda I)^{-1}Y`. This requires no primal cross-feature moment C. A fresh prediction is `(x_query X^T + z_query Z^T)*alpha`. Support Gram matrices and targets suffice for the fit, but not for arbitrary future predictions without

query-to-support evaluations. Retained feature rows are one sufficient deployment resource; a callable kernel port is another. The dual route trades feature-sized algebra for support-sized storage/solves, without a universal cost ordering.

This makes the acquisition-evidence choice route-dependent. A and B alone do not generally supply C or H for the primal update. Aligned X,Z and retained Y can; alternatively use sufficient cross-moment resources. The dual route uses aligned support kernels and Y but must retain a deployable query-evaluation path. Raw inputs can regenerate old or new features when needed; they are unnecessary for these algebraic fits when the required feature/kernel resources already exist. Existing labels can be reused if retained and still meaningful. New feature or kernel extraction remains work. Old summary statistics are not automatically adequate preparation for either arbitrary later donors or fresh deployment.

An iterative comparator can also start at `(beta_old,0)`, preserving original linear predictions before updates under fixed concatenated features. The updated joint optimum need not preserve old predictions or held-out quality. Keeping the old coefficients preserves a callable reader only while its feature/preprocessing path remains available. Incremental and warm-start simple methods belong beside fresh fitting as serious references; do not grant a proposed meta-learner savings by forcing its comparator to restart unnecessarily. Linear task adequacy and total cost remain empirical. No code, solver timing or model run follows from this ordinary-mathematics baseline calculation.

### S29. Reuse across contributors and operations

**Definition attempt within the reusable-consumer direction.** A stronger constructive target has two independently varied axes: the source of observations and the operation performed on them. An observation interface is reusable across operations if previously learned identity/correspondence and relevant evidence can serve the next operation without relearning those parts. New quantities, semantics and executor calibration are still charged. This is a prospective investment question, not an established transfer law or selected experiment.

A worked contract uses reachability and minimum travel time over the same network. Both need node/edge identity; minimum time additionally needs durations and a consumer for them. Keep the established topology interface initially fixed, permit declared duration teaching, and ask whether the new operation can reuse its correspondence. Existing executors supply the algorithms; a classification consumer is not presumed to know them. A typed graph is a serious realization of the common interface, not a deliberately weakened alternative.

**The missing combination makes reuse testable.** Given source D0 with operation O0 and O1, calibrate a new source D1 through declared primitive evidence, then ask whether O1 can consume D1 without new end-to-end O1 answer supervision. Record all primitive labels, paired data and receiver/interface adaptation. The unseen combination is not supervision-free when its component meanings were taught. A new duration reader is allowed; pretending durations were in the old interface when they were not would manufacture a failure. Matching held-out whole-task

quality and retained O0 use is the endpoint, not merely filling the matrix cell.

Compare reuse with operation-specific interface fitting under the same evidence; both may reuse all legitimate prior labels and computation. Do not charge a new label budget only to the comparator or require it to restart optimization. If reuse saves topology/correspondence optimization or new teaching at matched quality, invest in the common observation interface plus separate consumers. If necessary repair removes that saving, shared early perception with operation-specific ports remains viable. Failure of one fit does not establish intrinsic information loss.

This advances S28 from new evidence under one task to reuse of interpretation under a new operation. It does not establish transfer of an absent internal algorithm. The existing S14 continuation cases and S8 positive mechanisms supply its foundation; no new closure theorem, model availability search or graph benchmark is selected. The remaining concrete question is which part of the acquisition interface is reusable before the next operation's answer labels are supplied.

### S30. Check the grafting branch against concrete heterogeneous fusion

**Question before bounded primary-source inspection.** S28/S29 examine reusable consumption, but the user's broader mission also includes transferring useful computation into a receiving model. Does a concrete cross-architecture fusion method retain donor benefit after donor runtime withdrawal, and what alignment, calibration, search or task learning does it pay? Separate full-body fusion, exported adapters, shared-trunk serving and connected inference. None is assumed to establish arbitrary grafts or native mathematics merely by using transport.

The bounded source pass will inspect a concrete weight-transfer mechanism and a current encoder-stitching mechanism, at most these two primary cases. Its decision is whether direct grafting supplies a sufficiently constructive alternative to continually adding callable donors to deserve its own next strategy contract. Read actual data/learning/retention scopes, not abstracts; no models, code execution, checkpoint hunt or reproduction. Existing analytical closures remain closed.

**S30.1 — normalization question before interpretation.** A transport plan moves probability mass; a coordinate map need not preserve that normalization. For nonnegative plans with row sums `1/a_out` and `1/a_in`, investigate the conditional bound

`maxabs(Q_out W Q_in^T) <= maxabs(W)/(a_out a_in)`.

If two outer layer plans each have row mass `1/L`, their elementwise geometric mean has row mass at most `1/L`. Raw use of all these plans could therefore make the transferred term small. This is a question about the *printed formula*, not a finding about the released implementation or reported runs: first check whether the code rescales/sparsifies plans before use. The interpretation-changing null is masked target-weight shrinkage with identical masks and interpolation strength; when donor scale is material, also preserve that scale in a correspondence-breaking control. A positive transfer claim should isolate donor-specific contribution from a helpful change to the target alone. No numeric run is proposed.

**Two constructive precedents, source scopes checked.**

- [Transport and Merge, arXiv 2602.05495v2](https://arxiv.org/html/2602.05495v2),
main and appendices A–D: paired-input activation correlations determine neuron
and layer transport; selected target weights receive transported source weights.
Optional adaptation trains base parameters with the transported term frozen.
Folding permits the target architecture to run without the donor. Appendix B
specifies 2,000 examples per dataset. Reported merge-only gains include Malay
categories and Indonesian average 38.43→39.18; medical average instead goes
46.30→46.23, then 47.87 with adaptation. General-task averages and individual
source-target pairs do not test sequential acquisition. The representation-space
theorem proves a linear product identity, not nonlinear behavioral equivalence.
The inspected paper does not fully specify adaptation/search cost or isolate a
shrink-only arm. These are external results, not our reproduction.

- [Revisiting Model Stitching, CVPR 2026 final](https://openaccess.thecvf.com/content/CVPR2026/papers/Mai_Revisiting_Model_Stitching_In_the_Foundation_Model_Era_CVPR_2026_paper.pdf),
§§3–6: frozen visual backbones are joined by trained tokenwise interfaces. Final
feature matching followed by task-loss training outperforms several alternatives;
matched self-stitches control for trainable module, position, loss and data.
Cross-model gains occur but not for every pair/position. At layer 22, fMoW
self-stitches score 69.9/68.9 and cross-stitches 72.2/71.8. A task-agnostic
interface trained on approximately 1.1M images is reused with newly fitted linear
heads. Shared-trunk deployment retains specialized suffixes. Thus the paper
supplies a positive feature-interface reuse precedent, not complete donor
withdrawal or sequential acquisition. Main and supplement were read separately
from earlier arXiv versions.

- The [stitching supplement](https://openaccess.thecvf.com/content/CVPR2026/supplemental/Mai_Revisiting_Model_Stitching_In_the_Foundation_Model_Era_CVPR_2026_supplemental.pdf),
A.2–A.3/B.4–B.6, charges classification training up to 100 epochs, early stopping
and three learning rates. VST stitch training uses one epoch over 558k pretraining
and 665k instruction pairs; multimodal training follows a broader recipe.
Its 4.3%/39% figures count extra encoder layers, not end-to-end latency. The
45.5%/84.2% figures average five normalized benchmark gains; one component exceeds
100%, so the full-model reference is not an upper bound. Prediction analysis
includes interference as well as rescue. Fresh heads and frozen-tail forward/
backward computation remain costs even when the interface is reused.

**Pinned weight-transfer specification check.** Root and an independent reader
inspected the official release at commit
`6a822ef33d386585c57fa4e7cdd79925454336a7`; no code was executed or models fetched.

The [activation extractor](https://raw.githubusercontent.com/chenhangcuisg-code/Cross-Architecture-Merging-for-Large-Language-Models/6a822ef33d386585c57fa4e7cdd79925454336a7/activs_llama3_modules.py#L194)
uses model-specific tokenization and masked token means: alignment is per prompt,
not token-to-token. It extracts attention and some MLP projections; that does not
establish that every extracted module is transplanted.

The [fusion consumer](https://raw.githubusercontent.com/chenhangcuisg-code/Cross-Architecture-Merging-for-Large-Language-Models/6a822ef33d386585c57fa4e7cdd79925454336a7/generate_hot_residual.py#L672)
maps attention Q/K/V/O. It multiplies geometric-mean layer weights by

`round(sqrt(L_pre L_post))`, then uses `Q_out W_B Q_in^T` without feature renormalization on that path. Selected-mode initialization copies original weights outside selected slices and computes `(1-alpha) W_base + alpha W_hot`, resolving the paper's interpolation/additive-formula discrepancy for this code path.

The [transport producer](https://raw.githubusercontent.com/chenhangcuisg-code/Cross-Architecture-Merging-for-Large-Language-Models/6a822ef33d386585c57fa4e7cdd79925454336a7/core/hot_transport_chunk.py#L125) uses uniform probability marginals, normalizes Q by its total sum and returns it without barycentric scaling. The intervening caller/save path and actual paper-run plans remain unchecked; do not assert those runs used unrescaled Q.

The [training/folding path](https://raw.githubusercontent.com/chenhangcuisg-code/Cross-Architecture-Merging-for-Large-Language-Models/6a822ef33d386585c57fa4e7cdd79925454336a7/train_hot_residual_sft.py#L535) freezes the transported buffer while training base parameters. Selected folding uses current base weights outside the mask, whereas training interpolates those weights with their frozen original copies. These can differ after adaptation; dense folding follows the patched linear function. Actual paper-run flags remain unverified. This is a conditional path distinction, not a demonstrated run failure.

**S30.1 disposition — conditional calculation, not a reproduced mechanism.**
For any output entry, nonnegativity gives
`|sum_uv Q_out[i,u] W[u,v] Q_in[j,v]| <= maxabs(W) sum_u Q_out[i,u] sum_v Q_in[j,v]`, which proves the proposed bound under its stipulated row masses. Cauchy–Schwarz gives the outer geometric-mean bound. Scaling both feature maps to unit row mass changes their product by exactly `a_out a_in`; this compares two maps, not the donor and target weight norms. The code's layer multiplier corrects the simpler raw-layer interpretation, while caller-side feature scaling is unresolved. Stop this bounded inspection here. A future transfer experiment should inspect its actual transported/target norms and compare shrink-only plus scale-matched broken correspondence. No explanation of the reported benchmark gains follows today.

**What changes our strategy.** Useful grafting is sufficiently concrete to retain as a branch alongside connected inference. The two cases occupy different points: trained interfaces can reuse a donor prefix/receiver suffix; direct weight transfer can remove donor runtime but its attributed mechanism and adaptation cost need stronger isolation. Neither makes the user's ambition unreasonable, and neither establishes that a universal capability atlas already exists. An initial working interface could expose which donor computation must remain, before deciding what to compile into the receiver. Compilation need not precede all useful acquisition.

For a denizen, the desired primitive is an operation that still does the intended thing after crossing between worlds. Correlation transport and Euclidean feature matching are existing coordinate tools, useful scaffolding. Our native-math question is whether intervention-defined operations have reusable domains of validity and composition rules across those worlds. No such learned law has been shown here. A failed graft may reflect its interface/optimization, not a proven hole in the source space; separating those explanations is part of the next constructive contract, not a reason to demand exact equivalence before proceeding.

### S31. What would justify acquiring an intermediate operation?

**Definition attempt before dialogue.** Let a donor operation `T` map current observations into an intermediate object used by two independently specified consumers `C0` and `C1`. Acquisition fits a receiving operation `T_hat` using a declared evidence budget. A useful reuse target is improved held-out `C1(T_hat(x))` without giving acquisition the new instances' or second use's answer labels, while retaining earlier receiver uses. The consumer must already be competent on the intended intermediate object, or its new learning is separately charged. This is a prospective functional target, not a theorem or selected run.

The initial lean is to identify a useful connected interface before compiling the donor contribution into the receiver. The strongest alternative is direct distillation from the outset. The extra intermediate stage is justified only if it supplies reuse, supervision, repair savings or deployment choices that the direct route does not match. Ordinary distillation is a legitimate acquisition route; terminology does not establish a distinct research contribution.

An independent strategy response sharpens the endpoint to donor-dependent benefit that survives a change of downstream use. Same-receiver task-label training and scale/support-preserving correspondence controls can help attribution. New inputs alone do not separate factual knowledge, representation and computation; no claim that the receiver lacked the algorithm or reproduces internal donor mechanisms follows. The unresolved constructive ingredient is one intermediate operation with two competent, independently specified consumers. Another stitched accuracy comparison would leave that object unidentified. Dialogue should decide whether this condition identifies useful reuse or unnecessarily narrows the program.

**Fresh dialogue round 1.** Two consumers are an investment question, not an entrance requirement: one use can justify assimilation, while two cosmetic readouts prove little. A connected-first stage is worth purchasing only when it changes the acquisition choice. The proposed weighted-network intermediate makes shared interpretation concrete, but richer edge/duration teaching cannot be compared with reachability-only labels as an architectural advantage. A shared direct learner may discover its own intermediate and should get legitimate prior learning. Receipt: `strategy_grafting_dialogue_r1.md`, fresh session `01a09d8d-7814-7c62-9b83-b8d12d37d097`.

**Root response before round 2.** Accept those corrections. The proposed learning-cost comparison does not yet resolve a strategy choice without actual learning curves; another finite network calculation would repeat S29. Also keep two evaluation contracts separate: a genuinely unanticipated operation withheld during acquisition, versus an anticipated multitask workload whose task labels may be taught from the outset. Direct multitask distillation is a serious option for the latter, not a matched arm if only it sees withheld-operation answers. Conversely, identical call counts can expose different amounts of teacher information. A useful next paper question must specify the anticipated family and available intermediate semantics, then identify what reusable preparation is worth retaining; it cannot obtain a learning-effort advantage from a stipulated graph.

**Fresh dialogue round 2 and adopted scope.** Retain revisable interpretation

within a family of recurring entities, attributes and relations whose meanings are stable; a new meaning needs new teaching. Preserve identified evidence, learned correspondence and earlier callable uses. The competing shared direct learner also keeps parameters, accumulated teaching and replay evidence. For an unforeseen operation, neither sees its answers during preparation; after reveal, both receive the permitted specification and teaching. Known multitask preparation is a separate contract. The deciding observation is a post-reveal learning curve: where does adaptation occur, what prior interpretation remains usable, and what total work is saved? Sufficient retained information alone cannot answer this economic question. This closes the on-paper S31 framing without choosing a new graph run. Receipt: `strategy_grafting_dialogue_r2.md`, fresh session `01a09d91-f1f7-7d00-98ea-89d2709a5f61`.

### S32. Does a new provider replace or complement the old one?

**Question before a third direction response.** The user's stream of newer models need not grow the number of retained providers forever. A new provider can replace an old one for the declared workload, coexist because the old one retains a useful conditional contribution, or replace only some uses. This is task- and interface-relative substitution, not a claim about all knowledge in either model.

Replacement favors economical migration while retaining prepared evidence and established consumers; complementarity favors selective joint use. The useful lifetime of an interface therefore affects what initial preparation can repay. Standalone superiority does not determine either choice. A route that needs less serving work may still incur expensive backfilling, calibration or repair.

The prospective bounded source question is whether a real embedding-update method preserves use of already encoded evidence while admitting a better new encoder, and exactly what new training or provider cooperation it requires. That would make replacement concrete without assuming arbitrary independently released models are compatible. It would not by itself show that an older donor has no remaining specialist value. The third dialogue must decide whether this source case changes the preparation strategy or merely repeats a sufficiency caution. No model, re-indexing job, benchmark or implementation is selected.

**Third dialogue selects the migration case, then a scoped retirement decision.** Fresh CLI session `01a09d95-8175-7662-9836-6233e1d132ba` read the paper's arXiv v2 main/appendices; root independently read the CVPR final main and three-page supplement. The case makes an interface outliving its original provider concrete. It does not settle S31's consumer-design choice or justify a compatibility survey. Receipt: `strategy_grafting_dialogue_r3.md`.

**Primary evidence.** [Shen et al., CVPR 2020](https://openaccess.thecvf.com/content_CVPR_2020/papers/Shen_Towards_Backward-Compatible_Representation_Learning_CVPR_2020_paper.pdf) train a new encoder with an influence loss through the frozen old classifier. Basic BCT uses old labeled training data; extensions use old-model outputs for new classes. Training runs 16 epochs on eight accelerators; incremental compatibility cost is not isolated. New queries can use old gallery embeddings. The three-version experiment trains on 25%/50%/100% identity subsets while keeping

the evaluation task fixed. Its Table 4 shows that compatibility with the original baseline does not preserve every improvement achieved by the second version. This is cooperative new-model training, not arbitrary released-API alignment.

The [CVPR supplement](https://openaccess.thecvf.com/content_CVPR_2020/supplemental/Shen_Towards_Backward-Compatible_Representation_CVPR_2020_supplemental.pdf), §2/Table 4, adds partial-backfill evidence for a separate two-model setup and reports the third model's same-model endpoints. At other operating points, compatibility can also differ. No seed spread or confidence intervals accompany the inspected tables. Do not extrapolate the partial-backfill curve to the three-version setting or interpret aggregate point differences as guaranteed per-item retention.

**One workload-relative decision from those reported points.** Use the currently deployed second query encoder with first-version gallery features as the reference. Here Q denotes the query encoder and G the gallery encoding version:

| Configuration | Search, TPIR at FPIR .01 (%) | Verification, TAR at FAR .0001 (%) |
|---|---|---|
| Original Q1/G1 | 22.57 | 41.45 |
| Currently deployed Q2/G1 | 39.00 | 56.34 |
| Replace queries only, Q3/G1 | 36.10 | 53.98 |
| Re-encode gallery, Q3/G3 | 74.12 | 85.66 |

Rows 1–3: main Table 4; row 4: supplement Table 4. These are published results, not a new local experiment. Under a no-point-degradation requirement relative to the deployed reference, query-only replacement does not qualify on these reported values. Retaining Q2 for G1 or paying to re-encode are distinct options; the table does not supply their economic break-even point. A future decision needs a declared tolerance and uncertainty analysis, not a threshold chosen to make retirement pass.

**What to preserve.** Keep gallery identity, encoding version and the actual deployed query/gallery combination, together with its quality reference. Old raw images, access and permission permit re-encoding; saved old features alone do not provide that route. The provider's classifier and permitted training data are acquisition resources for the compatible-training route. Moving that work upstream does not make it free. Continuing to serve the old query encoder remains an option when replacement training or re-encoding is unavailable.

For a declared future workload, compare migration preparation, one-time re-encoding/repair and recurring query/storage work separately at adequate quality. No measured costs here select permanent retention or retirement. The substantive decision is narrower: **do not retire the working Q2/G1 configuration merely because Q3/G1 improves over Q1/G1.** A better same-version encoder can still be a worse replacement against already retained evidence.

**Residue for the growing-space mission.** An old contributor can retain value through compatibility with accumulated preparation, without possessing unique facts or an irreplaceable algorithm. Conversely, saved embeddings can remain useful for fresh queries after their producing encoder stops serving, provided a compatible query/consumer path exists. This preserves corpus-derived evidence, not all knowledge in the retired model. The native object is substitution within

an operational context, with the retained evidence and consumer included in that context. No new learned law, global dominance result or architecture is asserted. This bounded source branch is complete; no further source or compute follows.

### S33. What teaching evidence should acquisition purchase?

**Definition attempt before source inspection.** Fix a donor operation, receiving learning procedure, useful held-out endpoint and acquisition budget. Ordinary teaching records input/output behavior. Intervention teaching additionally records the response when a declared internal state/component is replaced or changed, including the input, intervention specification and source of the replacement. These are different evidence channels; S1's observational ambiguity does not prove that the second teaches useful behavior more efficiently.

The decision is whether to allocate acquisition effort to internal interventions or targeted ordinary examples. The strongest simple alternative uses valid input counterfactuals or hard-example selection that deliberately varies the same task factor. Internal interventions can expose otherwise rare dependencies, but they can also create unfamiliar states, transmit donor artifacts or simply add labels. The required comparison charges teacher generation, alignment search and student optimization; it does not grant the intervention route extra teaching unnoticed.

An independent response favors one bounded primary causal-distillation case. Read what the student learns—internal correspondence, useful outputs or both—and whether the reported comparison identifies an acquisition benefit. Agreement with an imposed causal model after extra supervision can be valuable without demonstrating efficiency. Preserve useful acquisition as the endpoint; internal causal equivalence is optional additional interpretation. No new identifiability theorem, model run, source catalog or architecture follows from this question.

**Fresh direction round 1.** Keep the bounded case, but do not ask it to settle superiority over informative ordinary teaching if that comparison is absent. Practical learning advantages can matter even when ordinary inputs could identify the same dependency in principle. Better optimization is a legitimate contribution, not a reason to discard the route. Internal distinctions need not matter to the desired valid-input use. Receipt: `strategy_teaching_dialogue_r1.md`, session `01a09d9e-5e9d-7c61-ac8a-7982a49277ec`.

**Primary case, read before round 2.** [Wu et al., NAACL 2022 final](https://aclanthology.org/2022.naacl-main.318.pdf), §§3–5/Algorithm 1/A.1–A.4, add a loss matching outputs after aligned internal interchanges. Each model substitutes its **own** source activations; teacher vectors are not copied into the student. Students share the teacher's hidden width, use fewer layers and initialize from teacher layers. Standard losses include ordinary output and cosine-state matching. On matched WikiText data, six-layer GLUE scores rise 75.80→77.14 after task fine-tuning; this is 1.34 points, not 1.77 points. MLM perplexity falls 15.69→13.45. Three distillation seeds each have five downstream fine-tuning seeds; those 15 runs are nested. Distillation uses three epochs and approximately nine hours on four accelerators. The paper does not compare targeted valid-input counterfactual teaching or equal total

acquisition compute. These are positive recipe results, not our reproduction, identified semantic-operation transfer or a global causal-abstraction certificate.

**Root response for round 2.** The source improves the constructive route even though it does not settle evidence efficiency. Its core causal loss compares effects of corresponding actions in each model's own coordinates. A common latent vector chart is therefore not a prerequisite of that loss; the intervention correspondence and shared output interpretation still must be supplied. The tested complete recipe also uses coordinate matching and shared architectural structure, so do not promote this observation to demonstrated arbitrary-model portability.

Do not require a human-readable name for the transferred dependency before a distributed learning benefit counts. Instead ask which part is reusable when a different donor arrives: ordinary input identities, output semantics, intervention addresses or their correspondence. This can motivate a causal teaching interface without pretending the additional forward passes and alignment work are free. The second dialogue should turn this into one acquisition choice, not demand an exact causal certificate or launch another source survey.

**Second dialogue adopts the intervention-response teaching branch.** A teaching episode contains identified base/source inputs, each model's own intervention, their correspondence, and comparable ordinary/intervened outputs. Reuse the receiving learning procedure and episode protocol; new donors still require usable addresses, replacement scope, output interpretation and informative pairs. Token indices and layer numbers are not portable meanings. The complete source recipe does not establish arbitrary-donor portability.

The discriminating future observation is a second-donor acquisition under the same procedure with explicitly charged new correspondence. Compare useful held-out behavior and prior-use retention with targeted incremental ordinary teaching at accounted expenditure. Protocol reuse and superiority of intervention supervision are separate results; either route can supply useful acquisition. This is a strategy contract, not a queued run. Receipt: `strategy_teaching_dialogue_r2.md`, session `01a09da2-34d9-7c81-b3ae-9dea77c275ca`.

| Preparation | Reusable when its meaning and dependencies hold | New work for a contributor |
|---|---|---|
| Base/source evidence identities | Same input instances and permitted task meanings | Tokenization, modalities or support may require fresh correspondence |
| Teaching episode and receiving objective | Same promised operation/output contract | Register the donor's permitted interventions and outputs |
| Intervention correspondence | Previously justified behavioral relation still applies | Address/role search or fitting; matching integer indices alone is insufficient |
| Teacher response bank | Fixed donor, inputs, intervention, decoding/evaluation state | New donor responses; a finite bank does not cover arbitrary later episodes |
| Receiver source states | Only while the relevant receiving computation remains unchanged | Receiver learning can invalidate cached states even when teacher responses stay fixed |

This dependency table is our protocol analysis, not a measured cache implementation. It does not require matching hidden dimensions for the core output-response loss; auxiliary losses and the actual intervention mechanism have their own requirements.

Changing coordinates also requires transporting the action's meaning: overwriting the same numeric indices after an arbitrary representation change is not generally the same intervention. No additional coordinate-invariance theorem is proposed.

**S33.1 — which responses become retention obligations?** Distinguish interventions used only to teach from operations the acquired system promises to expose. If only ordinary task behavior is promised, preserving every old teacher's counterfactual surface is an additional restriction, not automatically capability retention. If an intervention is itself a promised operation, its meaning and adequate response must be retained alongside ordinary uses.

S1 already allows donors that agree observationally but differ under an intervention. Mapping both to one receiver action can therefore create conflicting teaching targets even when their ordinary-use contributions are compatible. This reuses the existing witness; it is not a new impossibility result. Keep intervention addresses and correspondences donor-scoped until shared operational meaning is justified. A conflict can motivate separate ports, revised alignment or a different teaching objective; unsuccessful joint fitting alone does not diagnose insufficient receiver capacity or a hole in either latent space.

### S34. Where should joint inference live?

**Definition attempt before selecting a source.** A candidate state is a proposed answer or intermediate world configuration with a meaning shared by the participating ports. Each specialist supplies an evaluative response to that candidate and its own evidence. A controller uses these responses to revise candidates. This is an inference interface proposal, not an assertion that every encoder exports a likelihood, energy, gradient or competent evaluator.

The denizen question is whether specialists can evaluate proposed moves well enough for their contributions to compose without learning a new joint reader. Common candidate meaning, usable evaluation and a competent search procedure are separate requirements. Known typed constraints may already admit a direct solver; that is a constructive realization, not a failed latent approach. A learned joint reader remains an alternative when constructing, calibrating or searching the candidate space is harder than learning to consume the contributions directly.

**So what:** combine specialists by asking each to improve the same developing answer, including combinations they were never jointly trained to answer.

**Dialogue decisions (three fresh rounds, 2026-09-14).** Evaluator competence may require paid reader training; absence of fusion labels does not identify pretrained contribution. The controller is reusable preparation, not permanently frozen. Self-composition establishes operation reuse, while an independent donor tests contributor portability. Fresh-versus-stale feedback diagnoses runtime use, not acquisition savings. The third round provisionally retains a reader investment but distinguishes participation, repeated use and inheritance of learned judgment by a later contributor. Source availability alone does not justify the image workload. Work one dependency/cost account before funding implementation.

(`01a09db3-c0ff-7941-b866-af38037beaa2`) and `_r3.md`
(`01a09db9-39b1-7122-984f-6eee10fbf305`), all under
`internal/codex_transcripts/`; ledger stores full paths and hashes. Round 2's exact agent-authored text was recovered from its session patch after CLI final output overwrote it. Round 3 wrote the board despite root-only custody; root relayed its three findings unchanged with explicit provenance, preserving IDs e1081–e1083.

**Selected primary execution account.** [Du et al., ICML 2023 final](https://proceedings.mlr.press/v202/du23a/du23a.pdf), §§4–5/C/G, combine evaluations on a shared noisy image using annealed MCMC. Score models permit unadjusted updates; separately trained energy parameterizations permit acceptance corrections. Image implementations initialize each noise level with a reverse step before additional updates. CLEVR self-composes one conditional model trained with one position label per image; training images already contain one to five objects. Five-position reported accuracy rises 57.4→62.3 with unadjusted HMC on the score model; it uses a learned external position classifier. MCMC arms match score-evaluation counts, but this is not a matched-total-cost comparison with ordinary reverse sampling. Explicit-energy training and extra backward passes cost more. ImageNet uses a separately trained noise-conditioned classifier; text examples mostly self-compose conditions, while independently trained component distributions are shown in 2D. This supplies an executable positive mechanism, not cumulative encoder acquisition, unseen-world generalization or local quality evidence.

**Worked lifecycle for investment selection (proposal, not an experiment).** Use S34's independently trained image prior plus noise-conditioned classifier as the single constructive starting case. The paper demonstrates this initial prepared composition. It does not demonstrate the following growing system; do not splice its result with another paper to claim that system exists.

The prospective joint use is image generation satisfying an object requirement and a scene requirement. A new scene specialist is valuable only if its contribution helps meet the scene requirement while the object requirement and image quality remain adequate. This is a bounded visual instance of reasoning over specialist knowledge, not a substitute definition of all reasoning or the mission.

| Lifecycle stage | Retained object and new work | Evidence boundary |
|---|---|---|
| Prepared starting system | Image prior, working candidate update procedure, an object evaluator and their shared image/noise meaning | Source supplies prior-plus-classifier composition, not our implementation |
| Contributor arrives | A scene encoder plus its actual permitted access; do not assume its embedding is already a candidate evaluator | Proposed donor; none selected or loaded |
| Acquire useful interpretation | Learn or calibrate a candidate-to-evidence reader if needed, including validity on the states the controller visits | First project investment; prior and existing evaluator preparation stay available |
| Fresh joint use | Reuse the prior and update procedure with the acquired scene evaluation, testing both requirements and image quality | Source does not establish this particular two-specialist result |
| Subsequent addition | Reuse the prepared inference path and old evaluators; charge the new reader, correspondence and any necessary repair | Repetition and incremental savings remain untested |

**First investment:** establish useful completed-candidate evaluation using the

contributor's available interface. Learn a reader only if that interface needs one;
noisy-state assessment and derivatives remain separate prospective investments.
Retain the prepared inference procedure and existing uses. This chooses connected
growth for the first investigation.
Donor withdrawal, a universal latent chart and a new jointly pretrained reasoner
are not requirements of this first investment. They remain mission branches whose
value can be judged after useful participation exists.

The competent alternative uses the same starting prior, permitted donor evidence
and acquisition examples to adapt a direct conditional generator incrementally.
Allow warm starts and replay in that alternative. Compare preparation plus recurring
sampling at adequate joint quality; a cheaper reader can lose through expensive
search. Direct symbolic placement is also relevant if the task is reduced to known
rendering rules, but this prospective task is natural-image generation, not a toy
where those rules silently supply the answer.

**First consequential missing observation:** can the frozen scene contributor,
through the proposed reader, supply useful assessments on actual candidate states?
The positive source establishes that a specially trained evaluator can do this;
it does not establish the selected encoder-to-evaluator conversion. Therefore the
next funded empirical block would test basic participation, not recurrence or
scaling. No such block is selected for execution now: donor, evidence, resources
and stopping criteria must be made concrete before a run. Fresh-versus-stale
feedback is a diagnostic arm only; direct incremental conditioning is the serious
investment comparison. Third dialogue adopts this dependency/cost analysis, not an implementation.
Donor-specific readers can pay through repeated use even if they do not reduce
the next donor's teaching. Do not rename the former as the latter.

**Lifecycle dependency account (paper analysis, not a new route).** The proposed
scene reader has the form r_i(E_i(x_t), c, t): it assesses a scene requirement c
using the frozen donor's representation of the current noisy image x_t. Both the
image and noise state vary during inference. Consequently a cache of E_i(x_old)
is generally stale after a revision; this selected mechanism retains fresh donor
encoding, not only a saved embedding bank. Gradient-based revision additionally
requires a usable derivative path or an explicitly different proposal mechanism.
An embedding-only service does not silently grant derivatives through its encoder.

This differs from r_i(E_i(o), h), where observation o stays fixed while hypotheses
h change. That second dependency can reuse one encoded observation across many
hypothesis evaluations, provided the retained reader can perform the promised
operation. It is not what the proposed image lifecycle has established. Both are
covered by S12/S34's access distinctions; naming the dependency prevents transferring
the second case's hoped-for cost advantage into the first.

What survives after the first scene acquisition is concrete: the learned scene
reader, donor access, calibrated requirements within its supported family, the
existing object evaluator and the working inference procedure. A fresh use changes
the requested scene and object combination within supported meanings while reusing
those learned operations. Same-meaning provider replacement tests portability;

acquiring an additional useful distinction or operation tests growth. Neither alone establishes reduced subsequent teaching. For a later encoder with the same scene meanings, reusing the old reader may require a newly learned input correspondence. Compare that route with fitting a direct reader to the new encoder using the same permitted teacher outputs, features and labels. For a genuinely new property family, the scene reader supplies no demonstrated interpretation; existing scene judgments remain useful alongside newly learned ones. Retained specialist use is valuable without claiming that each new interpretation became cheaper to learn.

The initial teaching must cover the candidate states the reader will assess. Clean-image labels alone do not establish useful judgments on noisy, imperfect or adaptively proposed candidates. Conversely, teaching a reader on such examples can be useful even if the donor was never noise-trained. Whether frozen features supply enough information is the participation question, not a prior impossibility. Compare a reader using informative donor evidence with the same learner deprived of that information before crediting the encoder; allocate the same labels and training opportunities to the direct alternative. Quality is judged independently of the score the inference procedure optimizes.

**Workload accounting and provisional funding disposition.** Apply S4.1 to the whole lifecycle. Let A_R and A_D be total preparation/onboarding/repair costs for the reader route and direct incremental conditioning, including any separately charged reusable preparation; let c_R and c_D be recurring costs at adequate joint quality. The reader route is cheaper over n queries exactly when $A_D - A_R > n(c_R - c_D)$, under this stationary accounting. Common sunk prior training cancels only if both routes really have the same access. Retaining a new donor adds storage and, in this candidate-encoding case, recurring forward work. Equal score-call counts do not equate gradients, memory or elapsed time. No measured quantities currently determine this inequality.

The analysis licenses a **bounded participation investigation**, not a claim of inherited interpretation or scalable hundreds-of-donors execution. Keep reader reuse for fresh scene/object requirements as the proximal question; test later provider correspondence against direct reader fitting only when participation exists. Do not invent a universal learned interpreter merely to make acquisition reuse sound stronger. If the intended workload cannot repay donor calls and reader preparation, direct conditioning is the sensible competing investment. This image lifecycle is now a worked option with explicit limits, not the chosen application of the entire project. No local image model or training job is selected by this paper analysis.

**Earlier investment proposal: completed-candidate evaluation.** Independent review identifies an avoidable bundle in trajectory guidance: scene interpretation, noise-state validity and derivatives need not be learned together. Keep the existing object-conditioned generator, produce a fixed budget of completed candidates and use the scene evaluator to select among them. This requires clean-candidate assessment, not a derivative through the donor. If a released contributor already supplies the needed judgment, no new reader training should be presumed necessary. The first comparison includes the generator's own adequate direct conditioning

controls wherever its actual interface supports the requested scene.

The deciding quantity is whether the permitted candidate set contains acceptable joint outcomes. Reuse S26's proposal-ceiling logic: terminal selection cannot exceed the fraction of tasks whose candidate set contains an independently judged adequate object, scene and image-quality outcome. The analogous graded ceiling is the best externally judged utility in each set. Neither ceiling is measured by maximizing the acquired evaluator's own score. Do not infer best-of-K coverage from a marginal success rate without the required within-task sampling assumptions.

If coverage is adequate, compare learned/acquired selection with competent direct selection under the same candidates and expenditure. If coverage is inadequate, selection alone cannot fill that gap; trajectory guidance, better proposals or direct incremental conditioning have a concrete role. A scorer advantage over random selection establishes only a local useful judgment, not efficient acquisition or new destinations beyond that candidate set. Approximate feature refresh is also an available engineering choice, but its quality must be measured rather than treating every stale cache as categorically unusable.

**Existing artifact check for this decision.** The selected source's [official repository](https://github.com/yilundu/reduce_reuse_recycle/tree/81177d99bea601e53396a9d35e37f14ab2ee7a98) was inspected at revision `81177d99bea601e53396a9d35e37f14ab2ee7a98`: complete 45-entry tree, README and three notebook output inventories. No eligible declared object-plus-scene candidate bank was identified in this scope. The image notebook has three image outputs and a fixed demonstration context; those are not an unselected candidate series for this question. Its README distinguishes an alternative tapestry implementation and unreleased infrastructure used for most large paper experiments. Checkpoints and training data links are not coverage receipts. No model weights, linked training corpus or new generator run were requested. This is a scoped artifact-eligibility finding, not global data absence.

**Pre-deferral disposition:** retain the lifecycle, but make completed-candidate coverage and useful clean evaluation the first prospective evidence purchase. Trajectory guidance is a later investment if proposal coverage warrants it. The source-only lifecycle account is complete; new evidence would require one suitable existing candidate collection or a separately bounded data-generation proposal. The fourth approach review selects one bounded data-acquisition proposal next, not another bank hunt. It does not authorize a model run or imply that the image workload is the project's highest-value application.

**Fourth review disposition (02:40 UTC).** Continue, revise evidence allocation. The image workload remains provisional; neither its source nor a low terminal coverage result establishes that it deserves trajectory guidance. Prepare one small candidate-data proposal with accessible components and explicit costs; learn a reader only if the available contributor lacks the required interface. The licensed claim is a concrete reusable evaluation interface and cheaper participation test supported by published prepared composition. Actual scene-donor participation, retention across additions and acquisition savings remain unmeasured. Receipt `strategy_periodic_4_audit.md`, session

`01a09dc5-c8af-7050-98ac-ed4203f6ed7e`; audit e1086–e1087, root synthesis complete.

**Deferred candidate-data design, preserved for reuse.** The full resource and selection specification is in this file at commit `f9ce821` (retrieve with `git show f9ce821:theory/CUMULATIVE_CAPABILITY_ACQUISITION.md`), plus the hashed resource and dialogue ledger entries below. This table consolidates that closed proposal; no run or compatibility success is implied.

| Item | Preserved specification |
|---|---|
| Generator | Official `pytorch-pretrained-BigGAN` revision `1e18aed2dff75db51428f13b940c38b923eb4a3d`, deep-128; 210,849,368-byte checkpoint. Noise/class/truncation interface, no discriminator or documented joint scene prompt. |
| Object evaluator | Installed torchvision 0.26.0 ResNet18 `IMAGENET1K_V1`, 46,830,571-byte checkpoint; short-side resize 256, center crop 224, official normalization. |
| Scene evaluator | Official Places365 revision `8a953ed56438726dc98bdef3796d042e7f1f171e`, ResNet18, 45,506,139-byte checkpoint; square 256 resize, center crop 224, official normalization. Square source images make the resize geometry coincide; tensor equality still needs checking. |
| Access status | Code, labels and successful headers only; 303,186,078 total weight bytes, no bodies acquired. Full weight hashes, loading, compatibility, memory and latency unverified. Installed torch 2.12.0.dev20260408+cu128, NumPy 2.3.5, SciPy 1.16.2; generator package absent. |
| Candidates | Four object conditions 208/281/339/817 (dog/cat/horse/sports car), four fixed seeds 0–3, paired noise at truncations 0.5 and 1.0: 32 distinct images maximum, all failures retained. Two requests per pool: scene classes 150 broadleaf forest and 319 street. |
| Signals | Sum dog indices 151–268 and domestic-cat 281–285; individual 339/817 for horse/car; single declared scene classes. Supplied label interpretation, not quality evidence. |
| Primary | Scene-only argmax, truncation 0.5, against object-only. Opposite-scene control uses identical images/scores. Exact uniform-selection expectation adds no model calls. |
| Secondary | Fixed first candidate, joint sum of within-pool object/scene ranks (ties object rank then stable ID), and supported truncation 1.0 remedy. No post-result promotion. |
| Practical screen | Net joint gain at least 2/8 versus object-only, at least 1/8 versus swapped scene, above uniform expectation; at most 1/8 object spoil. Report recoveries/losses, spoils/repairs and baseline-adequate denominator. A one-object-block gain stays scoped to that block. |
| Endpoint | Two independent blind image readings for object, each scene and usability, with clear/ambiguous/absent labels. No scores or winning arm disclosed. Coverage is acceptable-candidate count, not a selector result. Shared candidate labels remain consistent across all comparisons; funding sensitivity to ambiguity makes the purchase inconclusive. |
| Dependence | Four object blocks; shared seeds, paired truncations and two requests are nested. Different rendered images have separate labels. Descriptive effects only, no general significance claim. |
| Ceilings | CPU float32/eval/batch1/two threads/one process; downloads 320 MiB/90s, compatibility+load 120s, inference 180s, peak RSS 3 GiB; 33 forwards per model including one fixed-input repeat, 99 total maximum. **45 minutes total effort**, including judging and the result audit. No fitting, gradients, porting extension or environment upgrade. |
| Stopping consequences | Positive primary retains only a locally useful evaluation interface; low coverage closes these pools, not selects guidance. Adequate coverage without benefit closes the selector/instance. Feasibility or judging failure licenses no behavioral conclusion. |

An authenticated Claude source-image read completed but mislocalized purple in Figure A2's third row. Root and an independent visual reader instead observed purple water/sky with green trees in several panels. This verifies access, not endpoint reliability; shared reader mistakes are not bounded by disagreement. The source-image call is separate from local probe forwards. Its exact temporary render was hashed and removed after cross-check; the public PDF is reproducible.

Provenance: `candidate_proposal_resources_20260914`, `source_image_judge_readiness_20260914`, and `candidate_proposal_dialogue_r1_20260914` / `candidate_proposal_dialogue_r2_20260914` in the ledger. Final deferral below supersedes the earlier conditional funding recommendation. The full historical proposal retains URLs, transformations, timing scope and root responses; no evidence has been replaced by an execution claim.

**Conditional residue: growth need not require every contributor on every query.** Independent strategy review worked a range-only case, not a new experiment. For a declared additive selector with unchanged old weights, let the old winner's margin against every alternative be at least Delta. Newly added score functions have known ranges [l_i,u_i] and nonnegative weights w_i. Their maximum possible adverse pairwise influence is R = sum_i w_i (u_i-l_i). If Delta > R, the winner survives without evaluating those contributors. If Delta <= R, only this certificate is lost; actual reversal does not follow. This is ordinary bounded decision arithmetic, not native structure discovered in a learned space or a proposed score semantics.

A contributor in [0,1] weighted w can be skipped at margin 2w but reverse a margin w/2 when its scores on the old/new winner are 0/1. Independently adequate reversals would make it useful despite being irrelevant on easy requests. If such unresolved requests have frequency p, its expected execution is p calls per request plus checking overhead. Actual p, quality gains, useful ranges and total savings remain unknown. This requires no learned approximation oracle; tighter learned intervals would be an additional paid investment. Changed calibration, weights or scoring rules invalidate inherited margins. Matching the full selector also inherits its mistakes. Retain this conditional distinction between compressed representation, amortized teaching and selective execution; no routing implementation or benchmark is selected from the argument.

**Final proposal disposition (fresh dialogue 2; root accepts).** Defer acquisition; no part of the proposed execution allowance is spent. The practical criteria are sufficiently specified, but the small possible participation finding has no concrete next use that justifies compatibility and judging work. This is an investment judgment, not a prediction of model failure. Receipt `internal/codex_transcripts/strategy_candidate_proposal_r2.md`, fresh session `01a09de6-8b58-71b1-8c14-363bffe8620d`.

Retain three corrections: report object spoils relative to baseline-adequate choices as well as all requests; matching/swapped scene selectors exchange the same images and therefore have identical aggregate object adequacy; disagreement bounds do not catch shared reader errors. Forest context versus broadleaf subtype is an unresolved endpoint choice, just as the horse score is a narrower proxy than the observable

horse requirement. Different truncation images need their own labels. No threshold rewrite, extra proposal round or judged model run follows. Reopen only if other work materially supplies compatible resources, credible endpoints or consequential reuse.

### S35. What would show that an acquisition inherits preparation?

**Definition attempt, before selecting further evidence.** A denizen should learn how to admit another useful guide, rather than merely collect guides. Let H_k be the retained preparation after k admissions, B the fixed evidence supplied about a new contributor, and U the admission procedure. The resulting callable behavior is U(H_k,B). A participation comparison against omitting B measures the newcomer's use; it does not identify the value of H_k. A history comparison must hold the new contributor, permitted new evidence and evaluation requests fixed while changing which retained preparation is available. Preparation costs and earlier evidence must remain visible. There is no asserted monotone learning curve or theorem.

The concrete obligation proposed for direction dialogue is a **second unfamiliar feature-provider admission to the same task consumer**, with original labeled support inputs retained, old provider representations retained and fresh query access available. Backfill the newcomer on those same support inputs; do not grant new target labels only to the proposed method. Compare inherited interpretation with ordinary incremental/warm-start fitting on exactly this evidence (S28.1), and with the same admission procedure without its acquired history. Keep the previously operational reader callable and assess actual old/joint use after any shared update. No dataset, model load or implementation is selected here.

The difficult attribution is whether H_k carries useful acquired structure beyond memorized support answers or a favorable optimization initialization. Both memory and warm starts can be legitimate benefits; the comparison must name which benefit is sought instead of defining them away. Likewise, an unprepared control denied all earlier data identifies the value of that evidence-plus-preparation package, not specifically a novel integration algorithm. Replaying all previous evidence is a serious alternative with its recomputation charged. A fixed frozen universal consumer can reuse initial preparation without learning from prior admissions; that is useful procedural reuse, but not evidence that the first admission teaches something aiding the second. S28's source establishes a precedent for the former, not the latter. Root's current lean is to make this distinction the next decision, not to buy another one-off composition demonstration.

**Independent comparison check.** Write A for retained historical evidence and H1 for the result of a declared history starting from H0. Comparing U(H1,B) with U(H0,B) identifies the retained package's value when A cannot be replayed; that package includes facts, support memory, optimizer state and calibration. Comparing U(H1,A+B) with U(H0,A+B) identifies prior preparation under common replay access and a declared marginal budget. Equal access is not equal cumulative exposure: H1 has already processed A, and that historical work is charged. Equal update counts need not equal FLOPs, encoded rows or teacher information. Both comparisons can establish legitimate warm-start benefits; neither alone isolates a novel

integration algorithm. H1 must descend from the same H0 with fixed architecture, permissions and newcomer/evaluation selection to interpret the difference as history rather than checkpoint selection or extra capacity. A subsequent provider withheld from history formation and fresh query identities are required for the intended transfer scope. This cross-check sharpens evidence attribution without selecting a model or another theorem.

**Root response to inheritance dialogue 1: one proposed retained state.** A stronger admission-learning claim is optional, not a new prerequisite for useful cumulative growth. The fresh dialogue correctly requires a coherent intervention: hold current features, reader and ordinary caches fixed while resetting only admission-derived state, if that separation actually exists. Otherwise report the broader package benefit. No mathematical language can manufacture that separability.

Take one concrete cheap state for analysis: the ridge regularization choice lambda1 selected during the first admission by a declared finite grid and fixed support fit/validation partition. Use a fixed objective normalization and recorded feature preprocessing; lambda values otherwise need not mean the same thing across episodes. The state includes the chosen value and provenance, not a newly claimed algorithm. On a second provider, retain the same old fitted reader and warm-start resources in both arms. One fits the expanded reader using lambda1; the other may select anew from the same grid, on the same permitted support evidence, with search charged. This asks whether avoiding repeated selection is worth retaining an empirical choice; it does not assume that the inherited choice remains adequate.

The reconstruction procedure g reruns the first admission's recorded grid search on its retained feature rows and labels, with the same partition, preprocessing, solver rules and randomness. It returns the same state under deterministic replay. Thus no new information is supplied by the scalar when these inputs are available; its possible benefit is avoiding reconstruction or repeated selection. A changed provider can alter the best regularization, so replaying lambda1 does not guarantee second-admission quality or preservation of old decisions. A fixed reasonable lambda, no-search warm start and fresh support-based selection are serious cheap alternatives. Their old/joint quality still needs fresh evaluation.

This identifies the deciding cost: if feature extraction or recurring model calls dominate, saving a small hyperparameter search may not materially change the total. If new search and repair cost less than the loss induced by stale regularization, retaining lambda1 is unattractive. No accuracy or timing follows from this analysis. It adds a low-cost inheritance baseline to S28.1 and closes the reconstruction exercise; it does not select a scalar-transfer experiment, meta-learner, new source catalog or theorem. The next dialogue must decide whether anything remains worth learning on paper here, rather than requiring stronger inheritance merely because fixed procedural reuse already has positive precedents.

**S35 disposition after fresh dialogue 2.** The paper-only inheritance framing is complete. Reconstructing a previous choice and selecting an appropriate new choice are different operations; replay fidelity cannot establish present suitability. Fixed procedural reuse, cached computation and warm starts remain legitimate growth

routes. No scalar-transfer run, stronger mandatory admission-learning criterion or further generic reconstruction exercise is selected. Receipt `internal/codex_transcripts/strategy_inheritance_dialogue_r2.md`, session `01a09df0-dfed-7972-b7ff-97e84d4376f2`. Three empirical uncertainties now control the strategy: useful contribution through an interface, retained interpretation and repair after additions, and consequential total work at adequate old/joint quality. These are dimensions of the problem, not three compulsory preliminary experiments.

### S36. Select a useful acquisition episode: a persistent scientific collection

**Historical priority, superseded by S37.** Preserve this proposal and its dialogues as history; query-side compatibility is no longer the first allocation.

**Decision attempt before direction dialogue.** The intended recurring request is: find evidence relevant to a scientific question in a collection that remains useful across encoder releases. An acquisition should make previously poorly served questions materially better while established queries remain adequate. This is a concrete beneficiary for the growing-space idea. It tests a semantic access capability, not transfer of an internal reasoning algorithm or proof that the corpus's facts reside in encoder weights.

The prepared resource is an existing collection, document identities, encoded vectors, its index and a working query path. This is a proposed deployment premise, not a claim that this repo has an eligible encoded collection: S6's rejected exports remain rejected. S32 supplies an external precedent for the migration decision, not a scientific-document dataset or demonstrated arbitrary released-model adapter. A collection that is cheap to rebuild or short-lived may not justify compatibility.

Root's preferred route for investigation is a **query-side compatibility interface** from a new frozen encoder to the retained archive, using a small declared set of paired anchor inputs and any permitted relevance judgments. Preserve the existing query path as a callable fallback and judge the operational combination, not merely its saved weights. Compare full re-encoding/index rebuilding with the new encoder, and keeping the existing system without acquisition. A separate new index or typed late fusion is also a serious route when complementary access matters; shared vector coordinates are not mandatory.

The preference reverses if the retained archive cannot adequately serve the useful new queries through the bounded interface while full re-encoding can, and its lifetime benefit justifies rebuilding. Failure of one fitted adapter does not prove that the old embeddings have irretrievably lost a distinction. Conversely, adequate new/old retrieval with consequential avoided rebuilding favors compatibility. A new model that yields no meaningful benefit is not acquired merely because released. No cost superiority is demanded when a worthwhile quality gain justifies expense.

The expected next addition is another encoder release or specialist querying the same persistent collection. That makes retained identity, relevance evidence and usable query paths worth tracking; it does not promise that a first adapter makes later mapping easier. New anchors, model calls, calibration, index work, storage and query costs remain charged. No local collection, model pair, learning run or data

acquisition is selected until the application-level preference is challenged.

**Root commitment after application dialogue 1.** Select persistent scientific evidence-finding, targeting questions that require distinguishing mechanism-testing evidence from topical similarity, including contrary findings, while preserving established query adequacy. Prefer query-side compatibility provisionally because better question interpretation may unlock distinctions already accessible in the retained archive. Retained vectors are an economic hypothesis, not a mission requirement; choose document-side expansion or rebuilding if that supplies the useful distinction, and no acquisition if a cheaper current-system remedy suffices. This selects the application and initial route hypothesis, not a model or run.

An illustrative recurring request is: “Which experiments actually test whether this mechanism caused the improvement, and which results limit that interpretation?” The system returns relevant evidence under a fixed inspection budget; it need not adjudicate the science or generate a conclusion. Topic-search adequacy is the old use; access to mechanism-testing and contrary evidence is the intended new behavior. Evidence finding can improve without information newly entering stored documents. It remains a narrower application than encoder reasoning or a chimera.

Keep document identities, source text and accumulated relevance evidence through all routes; their value need not require retaining old vectors. Historical encoding cost is sunk. The prospective advantage is avoided future rebuilding, continuity or other declared ongoing constraints over recurring use. Do not manufacture an index solely to pretend it has an avoided rebuilding burden. A real deployment premise can be selected before local resources exist, but it is not an observed cost saving.

The actual deployed query entry point must preserve old use after routing or result combination changes; merely keeping an old callable encoder is insufficient. New anchors teach correspondence, while relevance judgments can teach selection. Give credible current-path repairs the same permitted relevance evidence; where needed, an old-encoder interface with the same learning evidence tests whether gains came from new labels/reader capacity rather than the newcomer. A separate index combined by document identity is a genuine expansion option, not a failure of the mission. Before an eventual run, lock the minimum useful gain g, permitted old-query loss epsilon, common inspection budget and interface-learning budget on held-out query families. Re-encoding is a comparator, not a quality upper bound. The present block settles the strategic choice without inventing numerical evidence or an experiment.

**Final application disposition (03:42 UTC).** Fresh dialogue 2 accepts the selected application and initial conditional route. No material application-selection decision requires another generic dialogue. The returned evidence supports a researcher's inspection; relevance must include contrary findings and never mean agreement with a query's premise. Better query interpretation cannot guarantee access to document distinctions absent from the retained interface. This is the scientific uncertainty that can favor expansion, not a reason to avoid choosing the investigation. Receipt `internal/codex_transcripts/strategy_application_dialogue_r2.md`, session `01a09e00-1c4d-7ce1-bd05-c0ea01bcb41c`. Selection-level strategy is complete; feasibility, attribution, retention and deployment value remain unproven. One future

successful admission would establish a bounded result for this operation, not a chimera, general cumulative growth or a discovered latent-space law.

### S37. User-requested priority reassessment

The user explicitly challenges whether S36 is the best approach and authorizes execution only after renewed review. Three independent assessments agree that query compatibility has no established first-priority justification. The presumed old index is hypothetical and query interpretation has not been located as the bottleneck. Scientific evidence finding remains a legitimate possible use; the compatibility-first preference and selection-level closeout are reopened.

The reviews disagree constructively on the next purchase. The fresh real CLI favors S28's fixed-candidate donor-dependent evidence selection, with direct native donor competence before any compatibility map. An independent mission review favors S33's intervention-response teaching against targeted ordinary counterfactual examples. The feasibility reviewer likewise rejects adapter training before native contribution is shown. These are priority judgments, not predictions of model failure.

**Root response before decision round 2.** Prefer a bounded S33 teaching-access feasibility comparison because it directly addresses causal acquisition and can use small pretrained models with objective linguistic outputs. S28's scientific panel still needs credible mechanism-sensitive donors and new relevance judgments; its lower nominal implementation burden does not yet mean lower epistemic cost. The proposed operation is grammatical number agreement under a distracting noun, not a new reasoning algorithm or a whole language capability. This is a new task, not a restart of the closed protein, SVB or write-boundary probes.

Primary public configuration metadata (no weights acquired) identifies two TinyStories GPT-Neo releases: recipient 1M, revision `77f1b168e219585646439073245fe87e56b3023e`, hidden64/eight blocks; donor 8M, revision `8612e3b15c66ffa94eaa6ee0de5c96edd2d630af`, hidden256/eight blocks. Both expose the same declared 50,257-token vocabulary and zero configured dropout. Actual tokenizer identity, parameter count, competence and CPU compatibility remain unverified. These small model names are not total parameter or byte guarantees.

**Claim attempt before compute.** For fixed grammatical base/source prefixes, compare the donor's valid-input number counterfactual with replacement of its own subject-token state after the first block. The same-number different-noun source is the lexical control; identical-source replacement is the mechanical identity control. The replacement should shift was/were preference toward the source number more than the same-number control if it exposes useful number-dependent teaching. A competent donor plus a receiver gap is needed before spending on distillation. Failure of the single declared address closes that teaching-channel candidate at this budget, not causal acquisition or the model's grammar competence. Replacing all residual states would trivially reproduce an ordinary source pass and is not a useful claim-bearing intervention here.

A prospective first block is CPU-only forced-choice scoring of a small fixed panel, with no generation/termination claim and no training. It would select whether

intervention teaching is worth a separately bounded comparison against targeted ordinary teaching; it would not itself demonstrate acquisition. Before running, lock rows, outcomes, confounds and resource ceilings. Round 2 must adjudicate this choice against S28 rather than allow another generic strategy loop.

**Decision round 2 and prospective lock.** The fresh CLI changes its S28-first preference to one S33 preflight, conditional on fixed alignment, bidirectional contrasts, natural counterfactuals, actual recipient errors and a finite decision rule. Its shell failed, so it reviewed the supplied proposal, not S37 on disk; round 3 must inspect this concrete lock and runner before execution.

Use past-tense **was/were**, chosen before inference because these story-trained models see past-tense narration. Four lexical families (dog, cat, boy, girl), each crossed with singular/plural subject and singular/plural distractor, give 16 prefixes: `Yesterday, the {subject} near the {distractor}`. Distractor is the next family cyclically. Eight plain prefixes omit `near the {distractor}` and establish an old-use reference. Opposite-number sources change only the subject's number; lexical sources use the family two positions ahead, retaining subject number and distractor. Both directions and all four number cells are retained. No rows are selected by model score. All noun forms and both scored continuations must occupy one token at matched positions/lengths; otherwise stop for structural ineligibility.

Intervene after GPT-Neo block index0: replace only the subject-position state with that model's own source state and recompute every later block. Other first-block states already contain original-subject information, so this is one remaining causal route, not a total number replacement. Identity swap must reproduce the base; same-number lexical swap tests arbitrary noun change. The natural opposite prefix is already part of the baseline panel and is the cheapest meaningful remedy. No model-to-model vector copying or address search occurs.

Let L=log P(were)-log P(was). For each base, orient shifts by +1 for a plural source and -1 for a singular source. Primary effect is mean oriented L change; subtract the equivalently oriented lexical-control change for specificity. Report both directions, all four lexical-family means, conditional binary probabilities, unconditional was/were mass and actual decoded choices. Four lexical families are the descriptive dependence blocks, not 16 independent population samples.

Predeclared practical funding criteria: donor correct on at least12/16, at least 3/4 in each subject/distractor-number cell, mean unconditional verb mass >=0.05; recipient correct on at least6/8 plain items; at least two donor-correct/recipient-wrong complex items; primary patch effect >=0.5 log units, each direction >=0.25, and mean patch-minus-lexical effect >=0.25. Source-following accuracy is diagnostic. Identity and fixed-input repeats must differ by <=1e-5 in scored logit margins; failure voids interpretation. These are local allocation thresholds, not population significance or a universal exact certificate. Report lexical spread with the effects.

CPU float32/eval/eager attention, batch8, two threads, no CUDA, cache=False. At most 16 model forwards/128 row presentations across baseline, lexical source, plain, identity, opposite/lexical patch and repeats. Remote release tree reports weight bodies 48,578,813 and112,405,309 bytes; cap all acquired files at192MiB, download

wall time120s, loading+inference180s, peak process RSS3GiB, total operator block30min.
No environment upgrades, model search or training in this lock. Weight sha256:
1M `07f9609ea882b8163ff3b23d40e2b82cb715d409631beb15c84b164f3877dae7`;
8M `22c355bfabebc1f6c861b3f5d7a801e96c7f6da4af4bb0f7780096ab82ea6716`.
Pin/tokenizer-check both releases; count actual parameters rather than marketing names.

If all practical criteria hold, fund the already specified bounded intervention-teaching versus ordinary/text-counterfactual comparison. Competent donor but failed patch closes this address; failed donor/headroom closes this pairing/task; matched lexical effect denies number specificity. No training rescue or localization sweep. All outcomes remain about this panel and accessible teaching channel, not cumulative acquisition. This preflight is not a generation-quality test and makes no termination or fluent-language claim. Exact rows and receipts will be retained.

S37 final design review inspected the actual lock and runner and gives conditional GO. Before execution the runner now checks both tokenizers and exact single-subject-token pair differences, checkpoints each completed batch, and runs under an independent 100 ms polling CPU process supervisor (120 s acquisition, 180 s compute, 3 GiB peak resident memory; enforcement granularity is one poll, not an OS hard quota). Streaming reads are bounded by remaining byte allowance. Execution, structural, loading and mechanical failures are inconclusive, not scientific negatives. Source-following choices are diagnostic. Review receipt: `internal/codex_transcripts/agreement_teaching_preflight_design_review.md`.

**Attempt 1 execution receipt.** The supervisor terminated the 180 s compute phase after 200.42 s total; zero scored forwards, peak RSS 592,384,000 bytes. Both pinned weight hashes passed; 163,329,006 bytes acquired. No competence or causal-channel conclusion is licensed. A 30 s import-only diagnostic observed optional device-backend package enumeration during torch import (16.31 s to finish torch), then did not finish all transformer imports within its cap. One execution repair is permitted: disable optional backend autoload for the CPU-only process using the installed library switch, save import-stage checkpoints, and retry the identical panel under unchanged resource ceilings. Preserve attempt1 separately. No model/address/panel/threshold search, package change or budget growth. A second execution failure defers this local setup, rather than triggering repair loops.

**Attempt 2: harness failure, not tokenizer incompatibility.** The identical-panel retry ended after 84.57 s at tokenizer alignment, with zero scored forwards and peak RSS 734,183,424 bytes. It passed imports but the downloader had saved compressed HTTP payloads as metadata: seven gzip files and one Brotli configuration file. Decompressed tokenizer JSONs are byte-identical (sha256 f6ed3d307010c244c22aeffbde05f419cf277c23e64cf98b673cac5449cfeff5). This is an implementation error, not a model-level structural failure. The downloader now requests identity encoding and explicitly decodes bounded response reads; owned cache metadata was normalized with before/after hashes and all JSON parsed without model inference. No package or model change occurred. There is no third run in this allocation. Scientific competence, headroom and intervention effects remain unmeasured. A fresh audit must decide the justified next allocation; do not claim the pair failed.

**Review boundary.** Independent collaboration custody review verified recorded counts, both reconstructed executed-source hashes, current weight/metadata hashes, and byte accounting. It did not replay the historical compressed payloads (not retained) or the root localhost regression. Two real CLI result-audit attempts could not read files and explicitly remain incomplete; brief invocation access checks also failed. These are distinct evidence tiers, not an audited scientific negative. This allocation has no third model run. S37 may not advance or be called audited until a real CLI session first demonstrates actual file access and completes its result review. Broader strategy work remains authorized. The next scientific purchase, if justified after that review, remains the unchanged competence/headroom/intervention panel; only positive accessible teaching evidence funds the ordinary-versus-counterfactual-teaching comparison. No claim of an absolute best route or of complete understanding is supported.

### S38. Which intervention knowledge is useful to inherit?

A denizen needs moves that improve useful future responses. The immediate allocation question is whether acquisition benefits from special teacher answers, from the receiver's internal training procedure, or from both. S37 is parked; its execution failure and unavailable CLI audit do not govern this independent strategy question. No new model run or apparatus follows here.

**Repaired proposition, after independent strategy review.** Fix the donor family, adaptive episode-selection policy, learner initialization, and utility on promised receiver behavior. Suppose a donor-independent simulator using only permitted ordinary queries and disclosed metadata reproduces each intervention episode's conditional joint law given the complete previous transcript, including its dependence on learner state and shared randomness. Induction over episodes then gives the same law for the learning transcript, trained receiver and utility. Simulator query, computation, preparation and storage costs need not be equal. Metadata cannot hide donor-specific alignment or source-selection work.

Matching one-episode marginals is insufficient; S5's shared-bit counterexample already establishes this point and is not a new result here.
This is standard experiment-simulation reasoning, not a discovered latent law. Donors agreeing on all permitted ordinary outputs have identical donor-imitation targets there; that does not establish equal value for external truth, future composition, or changed environments. Those require their own target relationship. Do not call this limitation a converse of the simulator proposition.

**Decision-changing distinction.** Keep three candidate teaching arms conceptually separate. Ordinary teaching supervises the student on ordinary inputs. A second arm supervises corresponding student interventions using targets obtained from ordinary teacher calls on explicitly constructed counterfactual inputs. A third uses the same student interventions but targets obtained from teacher interventions. The second-versus-third contrast concerns teacher access; the first-versus-second contrast concerns the receiver's training pathway. Common ordinary losses, learner initialization, episode support and effort accounting must remain explicit.

This is a three-arm design question, not a queued experiment or an assertion that an arbitrary internal swap has a semantically valid text counterpart. A vocabulary-valid token splice need not be a task-valid counterfactual. When a proposed ordinary surrogate differs, it only rejects that surrogate; it does not prove that every ordinary-query procedure is insufficient. The useful endpoint remains behavior and prior-use retention, not fitting an imposed mechanism for its own sake.

Independent reviewer `intervention_value_review` recommends acquisition efficiency as the first benefit to investigate and warns against another generic sufficiency campaign. Root independently identified the same teacher-target/student-pathway split. Inspect the published loss and ablations next, then state the smallest unresolved contrast. Existing mathematics is scaffolding; the native candidate is an interchangeable move defined by preserved and changed behavioral roles across contexts and contributors, not a shared residual coordinate or matching layer ID.

**Published losses do not resolve the three-arm contrast.** [Wu et al. (2022), Algorithm 1, §§3–5](https://aclanthology.org/2022.naacl-main.318.pdf) forms both teacher and student interchanges, then matches their outputs alongside ordinary losses. Source-state values remain on the student's differentiable computation path. Reported ablations vary alignment, layer count, data fraction and auxiliary losses, rather than replacing teacher intervention targets while preserving the student intervention objective. Thus the source supports the combined recipe; it does not identify the separate value of special donor answers. This is a source-specific missing contrast, not an assertion that no paper has tested it.

A useful ordinary-access comparator is [Feng et al. (EMNLP 2024), §§3–4.6, Table 2](https://aclanthology.org/2024.emnlp-main.333.pdf): construct label-changing text edits, generate supporting/refuting rationales, and teach through ordinary language-model training. Its equal-example-count comparison reports 33.01 to 36.28 for one standard-rationale baseline after replacing half the original examples with counterfactual ones. Equal example count does not equal teacher queries or training tokens; generation and five-path filtering add work. The paper supplies an ordinary-input precedent, not a controlled comparison with internal intervention teaching or proof that its edits isolate causal mechanisms. Its original-versus-generated discriminator is not a gold-label validity test.

**New control obligation from independent source review.** Distinguish a trained composite's dependence on its donor input from a valuable contribution of donor pretraining. Post-training zeroing may only induce a distribution shift. A matched adapter trained with the same selection budget on raw/public input, ordinary donor answers, or suitable untrained representations is a stronger acquisition baseline. Nonlinear adapters are allowed to do useful work; account for that work and ask whether pretrained access changes the attainable utility–effort curve. This is our operational analysis, not a theorem that all such baselines are equivalent.

**Nonlinear interfaces need contribution tests, not a blanket linearity rule.** [Sutter et al., NeurIPS 2025 final, §4 and Appendix I.2.2–3, pp.6,38–39](https://proceedings.neurips.cc/paper_files/paper/2025/file/dbb98528c9870377f3f0d133aae6050b-Paper-Conference.pdf) prove their unrestricted-abstraction result under countable inputs, layerwise

input injectivity, strict output surjectivity, matchable orderings, and a network that already solves the task. Their empirical random-network alignment result has a significant qualification: its main IOI split separates sentences but not names. Under disjoint name sets, random-network alignment fails in the reported setting while trained-network nonlinear alignment succeeds. Alignment training uses two epochs over one million interventions. This is neither a cheap mapping guarantee nor an impossibility theorem for useful nonlinear grafting. Root checked the final PDF directly after independent source review; its SHA256 is 80a9c16eea3c447730192b88a0ac9945ebac603d9852961268f6df197919fcea.

Our resulting allocation rule: freeze the interface before genuinely fresh entities and combinations, and compare pretrained access with equally informed retrained controls at matched selection effort. A failed post-training donor ablation is not enough. Useful engineered composition, acquired pretrained contribution, and recovery of the donor's original mechanism are three distinct achievements. Standalone donor task accuracy is not a universal acquisition requirement: a useful representation may need a trained readout. S37's native agreement competence criterion was specific to the donor operation it proposed to teach.

The source's name-disjoint result is a constructive clue for the mission: richer maps need not erase the distinction between useful pretraining and fitting the adapter. It is a published task-specific result, not our experiment and not proof of cumulative acquisition. Prefer assessing operational transfer and its effort over policing the linearity of a chosen coordinate chart.

**Training-path calculation before another source check.** Write a student's patched hidden state as z_theta=(1-M)h_theta(x)+M h_theta(s), with a fixed selection mask M and all unpatched base context held in the downstream function g_theta. For loss ell(g_theta(z_theta),y), the encoder-side gradient contains D_z(ell o g_theta)[(1-M)D_theta h_theta(x)+M D_theta h_theta(s)]. Ordinary counterfactual training instead contains D_theta h_theta(tau(x,s)). Equal teacher targets alone do not equate these paths. Equality requires an appropriate student-side identity (and matching remaining context/dependencies) throughout the parameter neighborhood used in training, not just equal predictions at one parameter setting. Full differentiation also includes downstream and other context parameter paths. This chain-rule calculation makes the proposed contrast explicit; it is standard calculus, not a new latent law or measured advantage.

**Symbolic-teacher precedent, independently reviewed.** [Geiger et al., ICML 2022, §§3–6, Table 1, Figure 4 and Appendix C](https://proceedings.mlr.press/v162/geiger22a/geiger22a.pdf) compares internal intervention training with input augmentation using a supplied symbolic oracle. On MNIST-PVR, typed internal quadrant substitution reaches 93.93% behavioral test accuracy versus 90.90% for input-quadrant augmentation; untyped intervention training reaches 0.09%. On MQNLI, augmentation already reaches perfect behavioral performance, while internal training produces stronger agreement with the specified interventions. Appendix C describes one million base/source pairs reused per epoch, a common symbolic label oracle and up to five epochs; total computational work is not matched. ReaSCAN's reported comparison

has no augmentation arm. These are published results, not local reproductions. Root and independent reviewer `intervention_value_review` checked the methods; the review is not a real CLI audit.

**Decision.** The source supplies a constructive student-training precedent without requiring extra answers from a pretrained donor. It does not isolate gradient routing alone: internal substitution also changes intermediate states and effort. The smallest useful unresolved comparison fixes base/source pairs, checks equality of oracle targets episode by episode, and compares held-out behavioral learning curves against total work for ordinary versus internal substitution. Equal endpoint performance can conceal acquisition differences. Better intervention agreement alone is not an acquisition benefit unless a later use needs that operation.
Do not train a large replication or add a detached-gradient arm before the basic contrast is useful. A symbolic teacher is an informative control, not evidence that arbitrary pretrained donors have interchangeable internal parts.

**Equivalence boundary derived from the contrast.** Let inputs have typed slots x=(x_1,...,x_m), and let tau_{i<-j}(x,s) replace base slot i with source slot j. Suppose a student's whole interface factors as h_theta(x)_i=phi_theta(x_i), with the same differentiable phi for interchangeable slots, no cross-slot context, no omitted bypass, and identical treatment of randomness. The downstream function may mix these components arbitrarily. Then

h_theta(tau_{i<-j}(x,s)) = swap_{i<-j}(h_theta(x),h_theta(s)).

This is an identity in theta, so identical targets, loss weights and episode weights yield identical mathematical gradients for input and internal substitution where derivatives exist. For nonsmooth operations, matching differentiation conventions is an additional condition. Optimizer paths coincide if optimizer state and numerical execution also agree; input work may still differ. This result requires an identity across parameters, not an observed one-point match.

Thus a student-training difference needs some failure of those assumptions, such as contextual mixing before the interface, nonshared role encoders, stochastic differences, bypass context or unequal objectives. It does not by itself establish extra teacher knowledge. For a deterministic symbolic oracle that reads each slot independently and then combines the slot values, its input and internal replacement targets are likewise equal. This defines a clean target control without assuming the neural receiver satisfies the same factorization.

The native question remains which substitutions preserve meaning across actual contexts. Coordinate masks implement a proposed move; they do not discover its validity. The factorization calculation is ordinary scaffolding, not a new law of latent space or a reason to make all future representations context-free. Context can be exactly the useful information a donor contributes.

## S39. Can live latent communication admit a different contributor?

A denizen needs another contributor's message to retain useful meaning during a continuation. S38 studies teaching into a receiver; this source contrast studies connected use of retained donor computation. Neither entails the other.

**Contract before implementation inspection.** A reusable message includes the receiver-relative continuation it enables, not just its tensor shape. Fix receiver parameters, prefix, positions, masks and state conventions. A cache may reproduce recomputation when it contains the same keys and values that receiver would have computed on the same prefix. Different contributors require additional evidence; a byte-preserving copy does not itself preserve interpretation. This specializes S5's continuation-sensitive port contract, rather than inventing another identity.

**Primary source boundary.** [LatentMAS v4, 3 August 2026, §§3–4, Appendices A–C/G](https://arxiv.org/html/2511.20639v4) autoregresses aligned hidden states and reuses layerwise caches. The lossless-transfer proof expressly uses caches produced by the same model on the same inputs. Reported backbone variants are separate configurations, not a sequence of mixed pretrained admissions; Appendix G suggests trainable adapters for heterogeneous agents. Its input/output map is ridge alignment over embedding matrices under a shared semantic-coefficient assumption. Appendix E.3's latent-reasoning/text-communication arm uses only the last 128 decoded tokens. Accuracy, token and timing reports do not provide the termination table required for our capability/cost claims. We therefore retain a same-model continuation precedent without adopting the efficiency headline or claiming training-free heterogeneous transfer. Root checked v4 after independent review identified it as newer than the initially opened v3.

**Pinned implementation inspection.** Official repository revision `9a9e4d331eb11430bd9e64754c6b252b06d73031` exposes one ModelWrapper in `methods/latent_mas.py`; roles call the same wrapper while carrying past_key_values. An optional second inference copy uses the same model_name, not a second donor checkpoint. Read-only source inspection, not execution or a claim about every community extension. Hashes and exact source paths are retained in the ledger.

**Independent strategy review.** `alignment_contribution_review` proposes the right diagnostic: in ordinary attention, K'=KR and Q'=QR^{-T} preserve QK^T for invertible R, but pairing Q' directly with the old K generally changes scores. Thus even equal-shape, functionally equivalent attention computations need not share a raw cache convention. This is algebraic scaffolding, not a discovered latent law; it does not claim every such transform is a symmetry of an entire position-encoded transformer. A compatible adapter can repair the convention.

The native target is a communication move whose relevant consequences survive new contributors and continuations. The cheapest ordinary evidence interface and receiver recomputation remain serious comparators. The next source-only check examines advertised heterogeneous extensions: do they actually pass latent information across distinct pretrained checkpoints, or combine ordinary tool/text interfaces? No model download, generation or training is selected.

**The heterogeneous extensions are actual candidates.** [Hybrid implementation, revision d9f0d2235d92f81874083d701db456b9c6a5f39e](https://github.com/nhminle/LatentMAS-Hybrid/blob/d9f0d2235d92f81874083d701db456b9c6a5f39e/methods/latent_mas_hybrid.py) loads distinct checkpoints, computes cross-model ridge maps from vocabulary rows, and re-encodes accumulated prompts under the recipient before appending transferred

states to construct a fresh recipient cache. It resets the retained hidden sequence
to the new model's states on switching. The [README at that
revision](https://github.com/nhminle/LatentMAS-Hybrid/blob/d9f0d2235d92f81874083d701db456b9c6a5f39e/README.md)
restricts intended use to shared-tokenizer models and leaves specialization versus
overhead benchmarking to future work. Root verified the switching path after
independent review by `intervention_value_review`. This is implemented cross-model
transport, not merely a tool/text integration and not demonstrated acquisition.

[AVP at revision e71453a85b718317eaf85b3d0546f1080f9cc96e](https://github.com/VectorArc/avp-python/tree/e71453a85b718317eaf85b3d0546f1080f9cc96e)
implements a different route: source output-head probabilities weight recipient
input embeddings; different tokenizers use an intersecting token-string vocabulary
and renormalize there (`src/avp/rosetta/project.py`). Its HumanEval pipeline defaults
to one transferred state, extracted after an extra EOS-token forward following
latent rollout. The recipient first processes that vector, then its own reviewer
prompt. The code supports multiple transferred states as a separate option.
Its documentation reports mixed cross-model outcomes. Those author reports have
not been reproduced here or checked against raw per-item results and termination.

**Smallest confound, found in implementation.** AVP's direct HumanEval prompt asks
for a function body; its receiving reviewer prompt asks for a complete function
and invokes a reviewer role. Therefore target-solo versus cross-model results are
not a clean message-contribution contrast. The first null is the identical receiver
reviewer prompt with no donor message. A same-position, same-scale message permuted
across requests then tests content dependence, separating it from extra positions
or generic perturbation. The inspected evaluator handles both a raw body and a
complete function; this is a prompt-control issue, not a demonstrated scoring bug.
This is an identified uncontrolled contrast, not evidence that prompting explains
the reported difference. The text comparison also changes
sender computation and recipient context; it compares whole procedures.

**Useful narrowing, not dismissal.** For AVP's probability-mediated channel,
matching the selected source logits up to an additive constant (at the same
positive temperature), recipient embedding rows, and normalization suffices to
reproduce the transferred vector. This concerns that message only. The source
state follows internal latent rollout and an extra token; an ordinary text API is
not automatically able to generate or query that state. Nor is the weighted mean
embedding an expectation over the recipient's nonlinear responses: S8 already
states the relevant affine boundary. Keep this legitimate no-fitting interface
as a candidate without treating it as a universal latent translator.

The next informative distinction is whether source latent rollout contributes
beyond projecting its ordinary prompt-prefill distribution, under the same terminal
token convention. Then compare equally budgeted recipient computation and targeted
sender text. Unique donor information is not required: useful computation or a
better quality/effort tradeoff can justify connected acquisition. A single switch
and a consequential receiver decision come before a multi-agent chain or a claim
that old operations survive future admissions. No experiment is selected yet.

**Projection review and uncertainty boundary.** Independent reviewer `alignment_contribution_review` verified the pinned probability-mediated paths. Complete source probabilities at the selected state suffice for the message; top-k access generally does not. The projection's optional diagnostics do not alter its main output. Normalization can take the mean outside the convex hull, so even a convex-mixture interpretation of the transmitted point needs qualification. Correct-versus-permuted gain would establish conditional message-content value, not pretraining-specific attribution or cumulative growth.

For the overlap route, let S be the shared-token set, p the complete source softmax at the chosen temperature, rho=p(S), and q_v=p_v/rho on S. The projected message is determined by q, independent of rho. Two source distributions with identical q but very different rho therefore induce the same message. Whenever a promised receiver decision depends on confidence that a relevant outcome lies in S, that message alone is insufficient. Carrying rho repairs this particular lost distinction, not the remaining mean-embedding compression or semantic token match. This is a property of the inspected operator, not empirical evidence that current models often encounter the problematic distributions. Shared-token count alone cannot bound rho. Do not turn this conditional diagnostic into another generic certification or benchmark campaign.

**Concrete next experiment shape, not a selected run.** One fixed receiver and one useful decision, not a chain: identical reviewer prompt without a message; correct message; within-panel message permutation at identical insertion positions and norms. If the content contrast succeeds, add zero-versus-positive source latent steps with the same terminal token, followed by a competent ordinary message and receiver extra-computation comparison. Positive ordinary communication is useful acquisition evidence too. Before any such run, specify a task whose donor or joint contribution is plausible and whose competent baseline fits the short CPU budget; do not substitute poor miniature language models simply because their weights are cached. The published implementation is a candidate, not that eligibility evidence.

**Coordinate check, not a new campaign.** The unnormalized probability bridge commutes with a recipient chart change E'=EA, g'(z')=g(z'A^-1): pEA=(pE)A. Source coordinate changes preserving the selected logits also preserve its message. The current Euclidean norm adjustment need not commute. For E=I_2, p=(1/2,1/2), A=diag(2,1), adjusted transport in the new chart is 3/sqrt(10) times the transported old adjustment. This is a positive scalar difference; a scale-invariant continuation erases it. Independent review confirmed the algebra and this qualification. No arbitrary whole-transformer symmetry or observed behavioral failure is asserted. If a useful-message experiment survives its first controls, compare the same message with/without norm adjustment before inventing a metric or fitting another alignment. Ordinary algebra checks an operational requirement here; discovering useful receiver operations remains the destination.

## S40. Can separately prepared contributions work together?

A denizen needs acquired tools to remain useful when another tool arrives. S39

found real communication implementations, but not a demonstrated sequence of retained contributions. The next question is narrower than another global-map search: can two receiver interfaces prepared separately be used together without joint fitting, and what prior behavior survives? This is the operational extension question from S5/S8.2, not a new definition or a demand for universal retention.

**Proposition boundary before source adjudication.** Freezing the receiver and old interface parameters retains their available computation, but does not guarantee that jointly invoking an added interface preserves old answers. S5's substitution bound requires the contexts actually reached during joint use; isolated pairwise success does not supply that coverage. No new synthetic experiment is needed to repeat this established distinction. A published separate-training/joint-use test could nevertheless provide a constructive precedent for growth.

**Constructive source result.** [Cache-to-Cache v2, §§3.3–4.4 and A.5](https://arxiv.org/html/2510.03215v2) trains cache fusers with both models frozen. Table 6 includes receiver-only fine-tuning and same-model sharing; different-model sharing leads on its four tasks, with unequal trainable parameter counts. A.5.1 combines separately trained fusers without additional training, reporting a higher aggregate score than either pairing. This is a meaningful connected-growth precedent, not our reproduction. The general training uses 500,000 examples; the ablation fuser has 478 million parameters. The receiver's multiple-choice generation cap is 64 tokens, without a termination table. No local capability or cost headline follows. A.5.2's universal interface still has pair-specific gates and does not improve every receiver over its best individual pairing. Neither experiment establishes repeated admission with prior-use retention.

**The released composition operator is concrete.** Root and independent reviewer `intervention_value_review` inspected [pinned wrapper lines 511–581](https://github.com/thu-nics/C2C/blob/113c3a9b2538cbf096a0477e1ec99ae2a2e0d12a/rosetta/model/wrapper.py#L511). Parallel mode gives each fuser the same current base-cache slice and adds their output-minus-base residuals once. Sequential mode feeds the updated slice onward. [Projector lines 947–1024](https://github.com/thu-nics/C2C/blob/113c3a9b2538cbf096a0477e1ec99ae2a2e0d12a/rosetta/model/projector.py#L947) compute gated contextual key/value updates. Same current slice does not imply an entire receiver-only trajectory. Table 13 has not been tied to an exact saved configuration or fusion mode. A bounded official-source check found both candidate fuser directories at [release revision f01fc3258b305e280e04c7238f4f2cf31b7dc70d](https://huggingface.co/nics-efc/C2C_Fuser/tree/f01fc3258b305e280e04c7238f4f2cf31b7dc70d), but no matching joint-run record in the checked model card, tree and examples. The chat example changes response inclusion and is not an evaluation substitute. No weights were downloaded. This scoped absence ends the metadata search. Pinned file hashes are in the ledger; source fetched in memory, never imported or executed. Review is strategy review, not a CLI audit.

**Why this changes the next question.** A candidate move is now explicit: add a separately prepared contributor's contextual update through an unchanged receiver. Ask how much of A's established useful behavior survives B's admission, and which joint uses become possible. Keep A-support, B-support and mixed-use cases separate; retain item-level corrections and regressions. Compare joint execution with simple

donor selection under declared information and resource access. Matching routing would still establish useful connected access, while narrowing the composition claim. Do not demand all capabilities improve on all inputs, or start a retention measurement program before the selected contribution is useful.

Parallel preparation avoids one within-step source of shifted fuser input, but the receiver can respond nonlinearly to the summed changes. Sequential fusion can also be order-sensitive. These are distinct predictions, not interchangeable settings. The highest-leverage strategy step is to derive a small consequence of this actual operator, then ask which observable would distinguish its failure modes. Training hundreds of millions of adapter parameters locally is not justified.

**Shared factors are a different proposal.** [Thought Communication, NeurIPS 2025 final, §§2–4 and Appendix A](https://proceedings.neurips.cc/paper_files/paper/2025/file/b2b502c3629beadda06311386d2c6f73-Paper-Conference.pdf) uses response hidden states, an autoencoder and an injection adapter. Its factor identification requires invertible smooth mixing, population distribution matching, Jacobian-support conditions and sparsity. Practical reconstruction plus an L1 penalty does not verify those assumptions. Its 500/500 training/evaluation setup and agent count experiments do not establish successive admission with retained interpretation. Independent reviewer `alignment_contribution_review` and root checked the final paper. Shared statistical factors need not be common truth or reusable interventions; receiver-only and input-only adapters remain useful comparators. Do not launch a factor-recovery campaign from an identification theorem alone.

**Native-math and holes check.** Cache addition and sparse Jacobians are ordinary coordinate tools. The denizen's proposed object is the contextual compatibility of useful updates: can they remain jointly executable, and where does that cease? This is not yet a discovered law or a proven hole in any learned model. A future space could expose stable compositional operations, but the present task is to identify useful operations and test their contextual limits. No new model run, training, runner or empirical artifact in S40.

### S41. What does adding cache updates predict at one attention read?

A denizen would need to distinguish changing where a read looks from changing what it reads. S40 supplies an actual key/value update operator. Before another run, derive its simplest consequence. This is conventional attention algebra used as scaffolding, not a new law of latent space or evidence of useful transfer.

**Proposition attempt: frozen-query composition.** Fix one attention head, query q, finite unmasked token support, attention scale and baseline key/value pairs (k_i,v_i). Let a_i and b_i be the scaled query products with two prepared key increments. The increments are evaluated against the same baseline cache and then held fixed. Let u_i,w_i be their value increments. Baseline scores are s_i; write p0=softmax(s), pA=softmax(s+a), pB=softmax(s+b). Under parallel addition,

pAB_i = (pA_i * pB_i / p0_i) / sum_j(pA_j * pB_j / p0_j)
yAB = sum_i pAB_i * (v_i + u_i + w_i).

Proof: substitute the three normalized exponentials; normalizers independent of i

cancel. This is exact on common finite support, with ideal positive probabilities;
use log scores in finite precision. Masked tokens are excluded, not divided by zero.
The receiver query, positions, mask and prepared increments must be identical in
all arms. A separately executed whole-model A/B run generally violates that contract.

**Two distinguishable consequences.** With the already prepared key increments zeroed, weights stay p0
and yAB-y0=(yA-y0)+(yB-y0) for this one read. With key updates active, attention
reweighting can interact with either donor's values. A nonlinear combined read
therefore needs neither nonlinear dependence of the fusers on each other nor a
new capability. Conversely, additive head outputs do not guarantee additive later
behavior. This identifies key-only, value-only and joint key/value ablations as
mechanism contrasts if a useful donor contribution is first present.

**What equivalence is operational here?** For this fixed query/support, adding a
constant to every score increment changes no attention probability. Key directions
annihilated by q are also invisible. The visible operation is a change in relative
attention odds, not Euclidean distance between cache arrays. Its scope is deliberately
local: a later query can distinguish keys this read cannot. A global quotient needs
future-query coverage (S5), not a declaration that these states are the same forever.

**Questions under independent review.** Does this decomposition predict anything
worth measuring beyond the attention implementation itself? Which useful failure
would be distinguished by the key/value contrasts? Can routing or a simpler text
message explain the entire behavioral gain before mechanistic work is warranted?
Independent reviewer `alignment_contribution_review` verified the formula and scope.
A fixed linear output projection preserves the value-only identity, but later
nonlinear computation need not. Do not re-evaluate a coupled fuser/gate and claim
the same prepared-increment intervention. Key/value ablations can disrupt a jointly
learned interface; they do not isolate proven addressing/content modules.

**Allocation decision:** this is mostly an implementation identity. Retain it as a
diagnostic for an observed useful system that regresses under joint use. It could
separate one-read reweighting from changed queries or later trajectories; testing
the identity alone earns no capability claim. Useful separate/joint/selection
evidence takes priority. No synthetic benchmark, model loading or new runner is selected. The formula is a
conditional prediction for a candidate intervention, not a reason to build apparatus.

### S42. Can a decoder contribute an answer representation without answering aloud?

The denizen's useful object may be the consequence of an input, rather than a
summary of its wording. This directly connects the user's decoder-to-encoder idea
to a candidate acquisition role. Earlier LLM2Vec evidence (S1) changes an encoding
backbone; S39–S40 distinguish repeated donor computation from prompt-state sharing.

**Question before source interpretation.** Let a donor answer distribution be
P_D(Y|x), and let E be an explicitly chosen consumer representation. A learned
fixed-length export R_D(x) might predict an E-representation of a donor completion
without generating that completion at inference. Ask what training target it uses,
which donor computation remains at runtime, whether useful task behavior survives,
and whether another contributor can use the export without new pairwise teaching.

S8 already shows why an average representation need not support arbitrary nonlinear continuation; do not re-prove that here. Avoid identifying input encoding, predicted answer encoding and reusable reasoning state as the same resource.

A second concrete uncertainty is admission cost: reducing cache-fuser parameters need not reduce the frozen-model forward work required for fitting them. Review these resource choices before claiming that either export makes the growing system small or inexpensive. Primary candidates under review: LLM2Vec-Gen (2026) and Latent Cache Flow. No run, architecture selection or new apparatus follows from the search.

**Source result and interface distinction.** [LLM2Vec-Gen v3, 29 July 2026, §§3–5 and Appendices C/D/H](https://arxiv.org/html/2603.10913v3) trains suffix tokens and projections with a frozen decoder, using generated responses and an embedding teacher. Retrieval uses a pooled projection; reconstruction uses a soft-prompt sequence. Inference still runs the backbone once. Cross-family embedding teachers and different response generators are tested; a same-backbone teacher is preferred, not mathematically required. Alignment-only nearly matches full embedding performance but loses coherent decoding. Latent chaining and agent communication are future work. Training uses 160,000 queries with response truncation at 512 tokens. Root and independent reviewer `alignment_contribution_review` read v3 after root's initial v1 reading; do not carry forward v1's thought/compression split or numbers.

[Latent Cache Flow v2, §§4–5 and B/E](https://arxiv.org/html/2605.22863v2) reduces C2C's trainable fuser substantially, but reports 52 versus 66 seconds per training step because frozen-model processing dominates. Its early-stopped/pruned results are compared with C2C's full-schedule checkpoint. The shared-context endpoint uses logits. Cross-context tests use two copies of one checkpoint and task-specific training; they do not demonstrate successive donors. Two training-time descriptions conflict. Independent reviewer `intervention_value_review` and root checked these limits. Smaller adapters are credible; proportional admission savings are not shown.

**Three roles, not one donor.** Separate the model generating training answers, the embedding teacher defining the target interface, and the frozen backbone predicting that target. Better retrieval than the embedding teacher alone does not isolate new knowledge from the answer generator. Cross-generator aggregate results also do not show that a particular new donor's useful competence was acquired. The most direct acquisition contrast holds receiving system, embedding target and teaching budget fixed, then replaces own-answer targets with donor-answer targets on a predeclared useful distinction. Ordinary answer-derived teaching is a positive candidate route and the required comparator for a privileged internal-access claim.

**Candidate sharing idea, not an implementation.** A common frozen predictor could carry separate learned suffixes/projections prepared from successive donors' answers. The original donors would then be needed for teaching, not necessarily runtime. This would be assimilation only if useful donor behavior survives on new cases; fitting teacher embeddings alone does not establish it. Keeping separate interfaces preserves access to prior predictors, not the combined system's achieved behavior. A fixed target encoder makes coordinates common; it does not make the same future operations valid. The paper's cross-teacher ablation permits exploring a common

target, but does not demonstrate this cumulative arrangement.

**Cost question before any run.** Frozen weights do not imply fixed activations: learned input suffixes change the frozen network's output each optimizer step, and a learned cache update changes the receiver computation used for its loss. Reusing a fixed prompt prefix might still remove part of this work under causal attention. Work out precisely which subcomputation is independent of the trained variables; include cache preparation, memory and remaining gradients. Do not infer cheap training from a small count of updated parameters.

**Native-math and holes check.** The proposed operational object is a predictable response consequence that a later consumer can use. Coordinate MSE and pooling are scaffolding, not that meaning. A readout can succeed while a further operation fails: the pooled retrieval vector and the decodable soft-prompt sequence must not be interchanged. No new model run, weight download or cumulative result in S42.

**Conditional reuse proposition, independently checked.** Suppose F is a deterministic causal decoder with frozen ordinary-token parameters and identical positional rules, masks and query-prefix tokens across interfaces. Interface d appends trainable suffix s_d and reads its hidden states through trainable head h_d. Every prefix layer state and KV entry depends only on earlier prefix tokens, by induction over layers. Therefore its cache C_F(x) is independent of every s_d and h_d and may be reused across their updates. Suffix activations remain parameter-dependent and must be recomputed; frozen network operations on the suffix still carry gradients.
This is an architectural conditional argument, not a verified optimized code path.

If a shared prefix costs C_p and an isolated suffix branch costs C_s, M separately queried interfaces cost M(C_p+C_s), versus C_p+M C_s with reuse, excluding cache transfer/storage and batching effects. The arithmetic is not a timing claim.
Keep each branch isolated: appending A then B under an ordinary causal mask makes B see A and changes the interface. A single pooled embedding cannot replace the prefix cache without a further sufficiency argument. Task-specific prefix changes, backbone tuning, bidirectional dependence, changed position rules or unaccounted stochasticity invalidate this reuse argument. Finite-precision replay needs a numerical tolerance if an implementation is later evaluated.

For training, cacheable prefix activations do not eliminate the response-target preparation or a reconstruction pass conditioned on changing soft prompts. Reusing all frozen activations would generally change the training objective. This locates one genuine reuse opportunity without promising that acquisition is cheap.

Independent reviewer `alignment_contribution_review` confirmed the prefix argument: detaching a prefix independent of the learned variables preserves their gradients. Isolated old readout preservation additionally requires all shared normalization, calibration, tokenization, target-encoder and position policies to remain fixed. Adding vocabulary entries can change generation softmax normalization even when old embedding rows are unchanged; preserving an external embedding readout is narrower than preserving generation. This is modular ordinary distillation with shared computation, not newly discovered compositional mathematics.

**Pinned implementation boundary.** Root read [official code revision fdec758db27029b33d60d44c3c79c76fbaadf63f](https://github.com/McGill-NLP/llm2vec-gen/tree/fdec758db27029b33d60d44c3c79c76fbaadf63f).

The encoder call processes the supplied sequence and selects the suffix states; reconstruction and alignment projections expose different outputs (`modeling_encoder_decoder.py:510–560`). Default training uses selected trainable token embeddings (`scripts/train.py:434–450`). The inspected encoding entrypoint does not implement the proposed cross-interface prefix reuse. Source inspection supports the dependency distinction, not a measured saving. File hashes live in the ledger; no fetched source was imported or executed.

### S43. Does the available teaching data contain a useful donor correction?

A denizen needs a tool that changes a useful decision, not merely another message. S42's source comparisons leave the actual contribution target unspecified. Before fitting an interface, inspect a small fixed slice of the official released response data, if accessible through bounded metadata/row requests. This is a data eligibility inspection, not a new model run, representative accuracy estimate or acquisition test.

**Expectation and decision rule before viewing rows.** Different released generators may answer identical queries differently. A clearly correct donor answer where the candidate receiver is wrong supplies a possible teaching distinction, not proof it can be learned. If no such case appears, do not claim donor incompetence: close this small data slice and choose a different source of evidence. Match exact query text and generation metadata before comparison. Censored/truncated responses, unequal instructions, task ambiguity and style differences can make apparent corrections meaningless. Prefer objective checkable content; no external judge API or model. No weights download, new runner or latent-state measurement is authorized by this inspection. Record exact row-selection rule and hashes if usable data is obtained.

**Pre-row selection, 2026-09-14:** official `McGill-NLP/llm2vec-gen-tulu`; first 16 rows of the published training split, comparing the smallest available response generator with the largest same-family response generator represented on those exact queries. Determine field/config names from metadata only. If this slice has no objectively checkable correction, close it without expanding the panel or claiming a general result. Bounded row API payloads only; no full dataset, weights or parquet sweep. Treat provenance honestly if the row service cannot bind its output to an immutable revision. No model execution or training.

**Observed slice, closed without expansion.** Both row-service revision headers match dataset commit `2d6b5a99c2bc2521dc4ded3c66c91052245869ab`. All 16 ids and query strings match; neither response is marked partial and no cells are service-truncated. This is separate from model generation: several stored answers end abruptly, and weight revisions, chat templates and finish reasons are absent. Root read all 32 answers; independent reviewer `intervention_value_review` read both answers for rows 8–15. This manual reading is necessary because text transport integrity does not establish target correctness or completeness.

The clean example is row 10: of 15 pizzas, four are small and five medium, leaving

six large. The donor computes `4*6 + 5*8 + 6*12 = 136`; the smaller generator invents one large pizza and answers 76. Both stored answers visibly finish this calculation. Other rows prevent treating the donor's full responses as gold: row 6 identifies primes correctly but falsely says their reciprocal series converges; row 8 misses an available legacy stack-depth query; several multi-part answers never finish. [Official reference for the technical check](https://raw.githubusercontent.com/KhronosGroup/OpenGL-Refpages/main/gl2.1/glGet.xml).

Raw selected rows, request URLs, revision headers, decoded-response hashes, row-by-row notes and arithmetic checks are retained together in [the single result artifact](../experiments/results/teaching_target_slice_v1/result.json). No model was run. This is one bounded external-output data inspection, separate from the five local probe blocks and their 15 scored CPU forwards. No new runner.

**Decision.** One usable correction exists, so the teaching proposal is no longer purely abstract. It is not enough to select a training run: a one-off omission may be fixed by a short direct instruction, ordinary calculation or answer checking. Those are real alternatives, not proof that the donor adds no value. A future acquisition claim needs persistent held-out improvement through the proposed interface at a declared total cost; no such claim follows here. Close this fixed slice. Do not expand it into a target-quality benchmark or reopen S37.

**Transferable residue.** Distinguish three failures: wrong donor content, a valid correction lost by the export, and a preserved correction not usable by the consumer. Target supervision must make them distinguishable. A correct subclaim inside an erroneous response does not license embedding the whole response as a correct teaching target. This concerns operational meaning, not vector geometry; no learned-space hole or new latent law has been demonstrated.

### S44. One worked evidence-selection operation

**Definition before evaluation.** Given a question q and four fixed source-derived records, return the record containing the most direct experimental support for the requested contrast. Output is a record id plus its supplied passage. This is retrieval, not an automated verdict on a paper's causal validity. The denizen's useful operation is choosing the evidence that bears on the particular question.

**Request.** Return the supplied record that most directly tests whether a learned alignment generalizes beyond familiar entities, rather than just fitting them.

These are short paraphrased records drawn from sources already inspected. They are an illustrative fixed input, not a deployed collection or held-out benchmark.

| Record | Supplied evidence | Scope |
|---|---|---|
| D1 | The nonlinear-alignment study compares trained and randomly initialized representations when evaluation names are disjoint from training names; their alignment outcomes differ. | S38, final paper Appendix I.2.3, pp.38–39 |
| D2 | The causal-distillation study varies losses and alignment choices within its teacher/student intervention recipe. | S38, DIITO source contrast |
| D3 | The latent-communication core's cache-continuation argument concerns the same model and inputs. | S39, same-model proof and implementation |

| | | |
|---|---|---|
| D4 | The response-embedding study varies its response generator and embedding teacher. | S42, source ablations |

**Worked selection: D1.** Root re-read the exact final PDF paragraph, checking its SHA256 against S38's receipt. The controlled name-disjoint comparison is present. This narrows the familiar-entity-fitting explanation in the reported setup; it neither identifies the donor's original mechanism nor proves a general pretraining attribution claim. D2–D4 address related, different controls and could answer other requests correctly. This reference interpretation is human-grounded, not output produced by an embedding consumer.

**Exact offered interface.** The released response-derived encoder accepts text, returns a pooled projected vector, and supports similarity ranking of encoded records. That operation could return D1 and its stored passage. It cannot itself write the explanatory qualification above. Using its separate soft-prompt sequence with a decoder would be an additional operation, and using a judge to assess causal validity would add a consumer not present in this retrieval contract. No such addition is smuggled into the proposed comparison.

**Serious direct comparator.** Search the same supplied records from the original question using lexical retrieval or explicit field matching; ordinary question expansion may also help and is a legitimate response-mediated route. The worked question includes an entity-generalization contrast that can make lexical matching easy. Returning D1 would therefore not by itself establish semantic reasoning or a benefit from predicted-response embeddings. Any later ranking comparison must hold the record texts, allowed information and relevance judgments fixed, and measure an adequate direct route. No ranking model or endpoint has been run here.

**Decision-changing boundary.** The offered retrieval interface is sufficient in type for returning a relevant passage, so a new decoder/judge is unnecessary for this endpoint. Its empirical adequacy remains unknown. No competent affordable local released-model endpoint is asserted. The request fixes what an eventual export must preserve; it does not select training, establish retention, or reopen S36's compatibility-first preflight. There is no existing deployed collection or established topic-search baseline to preserve in this worked example.

**Fresh direction dialogue.** `resumed_frontier_adversary` first rejected comparing architectures that serve different decisions; the second round accepted this narrower operation and withdrew an unsupported assumption that an existing index was available. Root checked the source passage before accepting D1. This is an independent strategy review, not a real CLI audit. No native law or learned-space hole follows from the hand-worked selection. Close this operation-definition unit without growing it into another catalog or claiming retrieval performance.

**Compute decision.** A targeted cache read finds an ordinary 12-layer, 768-wide encoder with CLS pooling, but does not verify executable completeness or relevance competence. No predictive-response adapter is present in the targeted cache-name check. Independent review rejects running the four records merely because a model is available: either outcome would leave the acquisition decision substantially unchanged. No model was loaded. Advance to a prospective paired comparison.

### S45. Prospective relevance reversal, not a new architecture

**So what.** Teach a compact system to find the experiment that answers the actual scientific question, then check that the lesson travels to unfamiliar papers without making it choose the same kind of experiment for every question.

**Operation.** For the same candidate records, changing the explanation under investigation can reverse which evidence is appropriate. For S44's example:

| Request | Appropriate preference | What the distinction does |
|---|---|---|
| Does the alignment survive unfamiliar entities? | D1 over D2 | Selects the entity-generalization control |
| Which component of this teaching recipe matters? | D2 over D1 | Selects the within-recipe ablation |

These are prospective reference roles, not measured receiver skills. They concern which experiment addresses a question, not whether its result proves every causal claim. New wording over D1–D4 alone tests wording/intent robustness. Transfer of a decision rule requires unfamiliar experimental records and independently checked relevance judgments; papers and related experimental families must stay together across train/test splits. Hand-authoring the distinction into every test record would limit the result to reading those descriptions, not full-paper reasoning.

**Cheapest structural null.** A question-independent preference for one record cannot reverse. Even a score of the form a(question) + b(record) has a fixed record ordering. This is the familiar additive-null issue from S21, not a new latent theorem. Query/document interactions can implement reversal using ordinary lexical rules or embedding similarity. Therefore reversal is a necessary task property here, not evidence that our representation is special.

**Which acquisition?** The records already contain the factual evidence. Teaching would make a conditional distinction more accessible, not introduce the paper's facts. That is a legitimate capability target. The claim is improvement in using supplied evidence on fresh cases, with the donor absent after teaching. It is not knowledge novelty, mechanism recovery or cumulative growth after one admission.

**Prospective comparison, separated by information access.**

- First evaluate an unchanged ordinary retriever and the cheapest lexical/field matching remedy on the fixed requests and records. They establish possible adequacy/headroom; cached availability does not establish it.
- Compare ordinary receiver adaptation and response-vector teaching using the same training questions, donor responses, reference supervision and preparation accounting. Both must answer fresh test requests without fresh donor answers. Different objectives/representation choices make this a recipe comparison.
- Include ordinary query expansion as a serious alternative. A fresh donor answer at test time makes this a connected route with additional information and donor calls; it is not a matched-information assimilation arm. An expansion predictor trained only on the shared teaching set would instead be an assimilated arm, with its own training and decoding work charged.

Own-response versus donor-response teaching is a separate attribution contrast with the receiving recipe fixed (S38/S42). Do not infer donor value merely because

two acquisition recipes differ. No special latent-access benefit can follow from a comparison in which both recipes receive the same ordinary answer text.

**Outcome contract before any run.** Score question-conditioned ranking on new record families. Pair the two questions over each evidence pair and cluster any uncertainty by source family, not paraphrase. Report each request family's change from its pre-admission endpoint; a pooled gain can hide degradation on the other family. Retention applies only after baseline adequacy is actually demonstrated. Useful aggregate gain and tolerated regression must be fixed before viewing test results; this design has not selected their numerical values or a powered sample. A one-case exact pass/fail certificate is not the primary verdict. If a direct route is already adequate, ask whether teaching reduces recurring work; do not manufacture accuracy headroom. If endpoints are weak, do not call it failed grafting.

**Selection boundary.** No training on the four-record illustration. A brief ordinary-retriever probe becomes informative only when a prospectively fixed panel and adequacy threshold can eliminate a concrete candidate before a more expensive comparison. The missing predictive-response adapter is not repaired by testing an ordinary encoder. No model, adapter, dataset panel or training run is selected by this contract. Close this design block; do not expand it into another source inventory or unconditional feasibility claim.

**Independent direction dialogue and philosophy.** Reviewer `resumed_frontier_adversary` accepts ordinary supervised relevance as a useful operation, adds unfamiliar-record reversal, and corrects the fresh-answer access mismatch. Root accepts these limits. This is independent strategy review, not a real CLI audit. The native candidate is question-dependent evidence preference preserved under useful substitution; cosine is scaffolding. A failed reversal could reflect conditioning, teaching or export limitations. It is not a proven hole in the donor's latent space. The broader chimera and encoder-reasoning mission remains; this is one possible observable operation within it.

### S46. Teach the needed operation before predicting an entire answer

**Question.** Does full response-representation teaching improve the S45 operation beyond directly learning the needed question-conditioned preference from the same training information? For this endpoint, an answer embedding is a candidate intermediate representation, not part of the output contract.

**Primary competitor.** Keep text representations fixed and learn a task-specific ranking readout from the same training questions, records and donor preferences. Reference judgments and any human validation must be available equally to both arms. A response-embedding arm may exploit additional ordinary response content; that difference must be declared rather than called identical supervision. Compare quality and total preparation/inference work, not just trainable parameter counts. No universal superiority follows: finite data, readout restrictions and fixed representations may prevent direct teaching from learning a useful distinction.

This local preference readout does not automatically answer unfamiliar operations. If predicting response representations earns its cost through reuse, test a later

operation for which its preparation was not jointly optimized (S29/S35). Do not demand that the first retrieval task alone establish the value of general reusable exports, or claim such reuse from that task's success.

**Alternative worked and corrected.** A donor might teach an explicit contrast dictionary: question interpretations joined to evidence interpretations, preserving source spans and scope. But a supposedly small matcher that recognizes negation, entity binding and disjointness would contain the very skill we need to acquire. Frozen-encoder lookup does not supply that interpretation for free. Perfect manual fields would move it into the builder.

A genuinely executable export could instead be a donor-written predicate in a fixed restricted language: literal/token-position tests, Boolean combinations and bounded binding patterns, with preference plus matched spans or `unresolved` as output. No hidden `understands_disjointness` primitive. The donor supplies semantic rules; the builder only supplies mechanical execution and checks. Semantic repairs, test-specific exceptions or a new parser count as further development. Coverage must accompany correctness; abstaining almost everywhere is not useful acquisition. No such predicate has been obtained or run.

**Decision after two-round dialogue.** Independent reviewer `alignment_contribution_review` proposed the dictionary, accepted root's hidden-interpreter objection, and prioritizes direct learned preference over building that interpreter. Keep executable donor predicates as a conditional secondary route. Question interpretation followed by evidence interpretation is conceptual pipeline complementarity, not demonstrated composition of two pretrained capabilities.

**Native object and scope.** The reusable object is a scoped experimental contrast whose appropriate evidence depends on the question. A dictionary join is ordinary symbolic computation, and a vector readout is ordinary representation learning. Neither is a discovered native law. Their value is making the acquired distinction and required binding explicit. No model run, new runner, parser or training is selected. The next useful evidence must discriminate acquisition choices; another worked dictionary or arbitrary cache smoke test will not do that.

### S47. Real paired questions before another model check

S36 already selected scientific evidence finding; S44-S46 sharpen its operation and comparator, not a reason to repeat application-selection dialogue. Inspect one existing annotated dataset for raw examples before designing more machinery.

**Specific candidate.** [Evidence Inference 2.0](https://aclanthology.org/2020.bionlp-1.13.pdf) links structured intervention/comparator/outcome questions to trial-report evidence and effect labels. Its trained encoder pipeline separates evidence identification from result classification. We need only the first operation. Conditioning matters in the published comparison; abstract-only data support smaller inputs. Those are external results, not competence of a local frozen encoder. This is narrower than distinguishing mechanism tests from topical discussion: select the passage relevant to the supplied outcome question, not give medical advice or adjudicate causality.

**Prospective data inspection.** At source commit

`a661e8c14f973398380c8865cf2f27a535aaaf6d`, inspect at most five training reports, selected by increasing numeric article id. Eligibility is two prompts with the same intervention/comparator, different outcomes, and verified abstract evidence with distinct nonoverlapping spans. Exclude every prompt flagged in the release README. Take the first eligible prompt pair by numeric ids per report. Preserve all valid annotations for those prompts. Selection precedes semantic reading; do not replace pairs after seeing whether they are easy or useful. Fetch metadata within 20 MiB total and only the selected source reports; no bulk article download. Parser correction before semantic inspection: the CSV uses True/False while its README says 0/1. Root's initial literal-1 filter selected nothing; that is not a data negative. Recognize both encodings, preserve all valid annotations, and allow one corrected metadata fetch (30 MiB cumulative cap). The pair-selection rule is unchanged; no model has run or semantic pairs been read.

**Expectation and confound.** At least one report may furnish question-conditioned passage preference without manually idealized records. Different effect labels alone do not establish different relevant passages. An annotation for one question is not automatically a negative for another. Root and independent review must read the cross-question passages. If none qualify, reject this bounded panel; no larger search or model is justified by that failure. Offsets must be checked against the supplied source text; do not silently repair labels. No model load or training.

**Separate composition obligation remains.** Independent strategy dialogue with `resumed_frontier_adversary` keeps S40's separately prepared joint use distinct from this terminal readout: test combined decisions against each contributor, declared selection and ordinary evidence communication, with competence established first. An aggregate of separate tasks is not a mixed-use task. Neither this data inspection nor successful retrieval would settle contextual compatibility of acquired moves or donor-independent cumulative reasoning.

**Observed data eligibility.** Five fixed training-report pairs were selected, with ten structured queries and no replacements. Four pairs are semantically usable if at least one exact source-bound annotation is available per question. Three pairs also have every checked abstract annotation exact. Of sixteen abstract annotation rows, fifteen match exclusive-end slicing and one matches neither convention; duplicates are included in these counts. The release's inclusive-end description does not match those fifteen rows. Report 30713 has an already supplied exact broader annotation alongside the malformed offset. Report 29047 is rejected: its question asks about FIO2 but the evidence concerns a PaO2/FIO2 ratio. Do not repair it or infer a denominator change from a ratio change. These are study reports; not every selected report describes randomized allocation.

**Predeclared direct-remedy check and result.** The 60-second-bounded CPU process finished in 0.3406 seconds using cached source text, excluding preparation. It used no model. Outcome-field token intersection ranks source-bound abstract sentences; the second arm restricts candidates to the supplied RESULTS section. Ties choose the first source occurrence. Root and independent reviewer `resumed_frontier_adversary` read every selected sentence and tied alternative.

| Diagnostic | Whole abstract | RESULTS only |
|---|---|---|
| Adequate selected evidence | 7/8 queries | 8/8 queries |
| Both questions adequate, with distinct appropriate selections | 3/4 pairs | 4/4 pairs |
| Queries with adequate and inadequate alternatives tied at the top | 2/8 | 1/8 |

The whole-abstract failure selects a background statement about triglycerides; RESULTS filtering selects the reported study finding. For sputum volume, the correct CLR passage comes first among three tied sentences; the other two concern added P&PD; and a subgroup. Thus the observed success is not unambiguous lexical discrimination. Supplied article identity, structured query roles and section headings substantially assist this operation. No uncertainty/significance claim is made from four selected reports. No generation or termination endpoint applies.

**Decision.** A direct remedy suffices on this inspected panel under its fixed tie-break. Close it without a learned encoder, training, panel expansion or rescue. This is positive task behavior of a simple method, not acquisition, cost superiority, mechanism discovery or a hole in a model's space. The conserved distinction is which outcome and comparison a passage actually reports, not common terminology. The richer acquisition/operation-composition questions remain open.

**Custody.** One [result artifact](../experiments/results/evidence_selection_null_v1/result.json) retains eligibility failures, source hashes, annotation references, sentence-level decisions, ties and manual-review provenance. One 107-line canonical runner reproduces the scores. Root replayed its final storage/I-O change and verified all sixteen scores, selections and tied sets unchanged while preserving the reviewed input. This was verification, not another experiment. Independent review assessed semantics, not a timing replay, and is not a real CLI audit. Local totals are six probe blocks, fifteen scored model forwards, and 1,065 apparatus / zero artifact-bearing physical code lines. S43's external-output inspection remains separate.

### S48. Can a transported move remain useful alongside another move?

**Definition/question before source inspection.** Treat an intervention as a move identified by useful changed and preserved responses over declared contexts, not by its vector coordinates. A transport procedure should preserve that role in a different model; composition asks whether a separately prepared second move still works after that change. One successful transported steering effect would be a bounded precedent, not cumulative acquisition or knowledge-module grafting.

Inspect one primary cross-model activation-steering case for actual behavior and its preparation bill. Compare target-side contrast examples/learning, direct prompting and native target steering where the source permits. Style or refusal changes must not become factual/reasoning acquisition claims. No local generation, verbosity line, model loading or new apparatus is selected by this source question.

**Bounded source finding.** [Chen et al., NeurIPS 2025 final](https://papers.neurips.cc/paper_files/paper/2025/file/4569a868e7aa891248832ec08445d071-Paper-Conference.pdf), §4 and Appendices A/F, demonstrates some response-language steering transfer using affine residual-stream stitches within model families. Receiver weights stay fixed,

but recipient clamp targets are recalibrated. Stitch preparation collects both models' activations on 180k samples and trains two epochs; the steering-model contexts have 128 tokens. Main text says 100 paired direction examples; Appendix F says 250 for feature/coefficient fitting. Root confirms the discrepancy in the final PDF. Language detection on 163 instruction-stripped prompts does not establish answer correctness or termination, and explicit language prompting is not an arm. General instruction steering is weaker; inspected sections do not test two-move composition. This is a simpler interface precedent, not established cheaper total acquisition. Independent source review: `intervention_value_review`.

**Operation transport calculation, independently checked.** Use column vectors, a unit source direction v, a target level a, and an affine stitch T(h)=Ah+t. The source clamp is C(h)=h+v(a-v^T h). For invertible A, direct substitution gives

T C T^{-1}(z) = z + Av [a - v^T A^{-1}(z-t)].

The write vector is Av; the read functional is v^T A^{-1}. They are not generally Euclidean duals. Mapping and normalizing v does not by itself specify this move. A Euclidean recipient clamp along u=Av/||Av|| equals this transported operation only if v is an eigenvector of A^T A, with target ||Av||a + u^T t. This is a full-domain algebraic statement, not an empirical gate for a learned model.

For injective rectangular A, any left inverse B gives the functional v^T B on t+range(A); extensions outside that affine image are not uniquely determined. For noninjective A, the source clamp descends to a well-defined operation on that image exactly when Av=0 or v^T k=0 for every k in ker(A). Indeed, two source states differing by k have identical exports but their post-clamp exports differ by -Av(v^T k). If Av=0, the exported operation is identity. On a restricted reachable domain the relevant condition concerns actual shared-export state pairs; the full-space criterion must not be imposed as an exact learned-model verdict.

**Composing two clamps.** Let C_{v,a} and C_{w,b} have unit directions, set rho=v^T w, alpha=a-v^T h and beta=b-w^T h. Expanding both orders gives

C_{w,b} C_{v,a}(h) - C_{v,a} C_{w,b}(h)
= rho (v beta - w alpha).

They commute as maps on the full space exactly when the directions are orthogonal, or w=sigma v and b=sigma a for sigma in {-1,1}: the same target hyperplane. Parallel incompatible clamps overwrite each other. After the v-clamp then w-clamp, the first coordinate becomes a + rho[beta-rho alpha], exposing possible overwrite. Pointwise agreement need not imply global commutation. Ordered tasks can legitimately require noncommutation, and commuting changes can be behaviorally useless.

**What changes the acquisition question.** An exported move may need its write direction, measurement rule, target and valid contexts, not just a direction vector. The paper explicitly recalibrates a recipient intervention; it does not claim exact conjugacy, so this calculation is not a refutation. Ask whether preparing a shared correspondence reduces recipient-specific work for a later useful operation relative to learning that operation directly. Charge recalibration and check independently prepared joint behavior when that is the intended use. No commutator-measurement

program or local steering run follows.

Reviewer `alignment_contribution_review` independently verified the transport, descent and commutation conditions and keeps them diagnostic. These are ordinary affine-projection facts. The native candidate remains the operation's changed and preserved responses under useful continuation. No structural hole in a real latent space, acquired reasoning capability or new native law has been demonstrated.

**Preparation comparison, September 14 continuation.** For the denizen, effort includes making a move usable, not only obtaining its direction. Let the exact weighted mean of recipient positive activations used for calibration be mu+. For a transferred unit direction u, the calibrated level is u^T mu+. Accumulating the full mean during those same forwards costs an O(d) vector accumulator and no additional model forwards. This does not assert equal wall time. A scalar retained alone cannot generally recover that mean after the fact.

If a previously prepared recipient reference mu0 is available, the direct candidate is d=(mu+-mu0)/||mu+-mu0||, with level d^T mu+. An exactly zero difference gives no direction and must be reported. Thus direct preparation can use the same new positive forwards. Preparing the reference must be charged; an unmatched shared reference need not work as well as operation-specific paired negatives. The paper does not establish an already reusable English reference, and its general stitch corpus cannot silently substitute for matched negatives. Independent reviewer `intervention_value_review` confirms this conditional accounting and source limit.

The consequential comparison is transferred versus direct recipient preparation on identical positive activations, equal calibration opportunities, and a declared reference policy. A transferred direction may still improve useful effects or sample efficiency; equal forward counts do not imply equal quality. Both methods must be credited with reusable preparation. Existing S4.1 and S31 already cover amortization and later-operation learning curves; no new generic cost theorem is needed. No reference-quality experiment is selected before useful move selection.

In the same source, section 4 also evaluates source-trained probes on down-stitched recipient states without retraining the probe. This avoids additional recipient task-training activations beyond stitch preparation, not recipient inference. It is a constructive readout-transfer precedent; it does not establish a state update, donor-exclusive knowledge acquisition or composed reasoning.

**Decision-changing distinction.** Readout reuse, calibrated intervention transfer and retained reasoning contributions have different preparation obligations. Evidence for one cannot pay the bill for another. Preserve this distinction when choosing a useful operation; do not reproduce probe transfer merely to obtain a positive result. Means and affine maps remain ordinary coordinate scaffolding; the target object is a move's useful effect, applicability and preservation of other uses. No new learned-space hole or local execution follows.

### S49. Does a saved response export receive the later question?

**Question and direction dialogue.** The denizen needs to use an acquired object under a later request without revisiting its producer. A proposed premise-update

example was withdrawn after root challenged its duplication of S24/S29 and its failure to distinguish new facts from new operations. Reviewer `resumed_frontier_adversary` then selected an exact interface dependency: can the prepared response export reach an existing consumer together with a new question? S43 retains response text, not learned exports; S47 is a lexical selector. Neither artifact answers this behaviorally. Do not reinterpret either closed probe as one.

**Pinned source trace, not execution.** Root rechecked the S42 official revision and exact file hash. In `modeling_encoder_decoder.py:207-237`, training encodes the original query and prepends reconstruction soft prompts to answer-token embeddings for decoder loss. At lines 545-551, a supplied `decoder_inputs_embeds` bypasses query encoding. At lines 563-612, generation consumes that prepared sequence and appends its own generated-token embeddings. The original query tokens or their cache are not separately passed to the inspected decoder path. Decoder pretrained knowledge remains available; this does not attribute all decoded content to export.

Passing a new `input_ids` together with a saved embedding override therefore does not condition this path on a new question: those IDs supply the output device but their content does not enter the decoder. This is a source-code dependency claim, not a model experiment. The ordinary no-override path instead re-encodes its input.

The arbitrary embedding override makes manually appending decoder-token embeddings of a new question technically expressible. That would change the conditioning sequence; a missing dedicated argument is not an architectural impossibility.
The inspected path alone establishes neither competence on that sequence nor its training cost. Likewise, successful original-response reconstruction would not establish new-question use. Inspect source training/evaluation before crediting it.

Reviewer `intervention_value_review` independently confirms this trace. The v3 paper's reconstruction objective and inspected decoding evaluation concern the original query's response; latent chaining remains prospective. No fresh-request use evaluation was found in the checked sections, not a claim about every possible use of the released architecture.

**Allocation consequence.** Keep the released method as a concrete response-prediction/retrieval candidate. Reusing its soft prompts for independently supplied requests is a prospective consumer capability, not an already available reasoning primitive. Saved ordinary answer text is the direct reusable export comparator; a structured record is eligible only with its extraction preparation charged.
No new model loading, decoder wrapper or follow-up dataset follows from this trace. The response recoverable under later requests is the native candidate object; pooling and soft-prompt coordinates remain scaffolding. An absent tested consumer is an interface gap, not a proven information hole in its representation.

**Next source question, declared before inspection.** Let K(y) compress an available answer or evidence text y, and let Q(K(y),r) use it under a separately supplied request r. Does a published prepared consumer actually exercise this conditioning, and what preparation made it work? Inspect In-context Autoencoder as one concrete candidate, not a new architecture catalogue. If it supports later questions, that would supply a consumer precedent, while predicting its input from an ungenerated

donor answer remains a separate acquisition problem. If it only reconstructs y, it does not fill the present gap. In either case, encoding available text is not exporting a donor's whole knowledge, and text retrieval/ordinary context remains the direct comparator. No local model run is selected by this source question.

**Source resolution.** [ICAE, ICLR 2024 final](https://proceedings.iclr.cc/paper_files/paper/2024/file/0b276510ec2d3f6613a8b60c41ff0438-Paper-Conference.pdf), sections 2.1-2.3 and 3.2.2, supplies this separate-request consumer. A LoRA encoder compresses context; a frozen decoder reads memory plus a separate prompt. Autoencoding/continuation pretraining precedes instruction training on 240k triples. Context-dependent response evaluation uses model judgments without a reported termination gate; no local quality or lifetime-cost claim follows. Section 3.3.3 reports that concatenating individually compressed spans initially failed, then worked after additional multi-span training, evaluated by continuation perplexity. Those spans share one prepared interface; they are not independent pretrained contributors. Independent source reviewer: `alignment_contribution_review`.

**Released path verified separately from the paper.** Root inspected official [revision 469a46886a92dd5e76b2d12a8bac0fb7ed7d4cdd](https://github.com/getao/icae/tree/469a46886a92dd5e76b2d12a8bac0fb7ed7d4cdd), without importing or executing it. The later v2 release is not silently identified with the paper's exact runs. `fine_tuned_inference.py:52-69` compresses `input`, then concatenates template embeddings, memory slots and separately tokenized `prompt`. Decoding disables the encoder adapter. In `modeling_icae_multi_span.py:228-261`, compression sees only context segments and memory tokens. Training construction in `training_utils.py:126-150` likewise separates context and prompt, with answer-only loss labels. The example loop recompresses each row; its dependency graph permits retaining memory for another prompt, but does not implement a persistent cache. Source hashes are in the ledger. No checkpoint or training data was downloaded.

**What this changes.** A prepared consumer for compressed evidence under later questions exists as a concrete precedent. Consumer training, rather than a vector space label, makes the operation available. The current missing connection is whether a predictor of a donor's response can produce inputs that this kind of consumer uses adequately. Joining two papers does not establish that connection. The target would be a consumer-compatible memory of a selected response, not an export of the donor's whole knowledge. Pooled retrieval vectors cannot substitute for these slots merely because both are called embeddings.

Single-memory use and multiple-memory use are separate investments. The reported multi-span repair makes that distinction experimentally motivated, without proving that all consumers need joint training. Keep direct saved text and ordinary-context reasoning as serious alternatives. No reproduction, new wrapper, predictor training or local model loading is selected; next work should identify whether predicting the consumer-compatible target supplies useful information, computation, access or effort savings relative to what the receiver can already do. Information novelty is not mandatory; repeating the same answer more economically can matter. S38's access controls and S43's teacher-correctness distinction remain applicable. This is a candidate dependency chain, not a demonstrated new reasoning model or native law.

**Consumer-response teaching, not a new branch.** For a response Y sampled from a donor given x, compressor K, prepared consumer Q, and predictor H, an optional objective is

E_(x,Y,r) KL[Q(K(Y),r) || Q(H(x),r)].

Specify the joint request distribution if r depends on Y. Teacher distributions are fixed targets; gradients still traverse the frozen student-side consumer into H. This may cost much more than fitting cached targets. It is ordinary downstream distillation through a reusable interface, not an additional source of information or a selected training run. Actual donor and consumer correctness remain separate. With stochastic targets, one memory may not realize the teacher-response mixture across all requests. S8 already gives the relevant mean-export warning.

Reviewer `alignment_contribution_review` identifies the consequential requirement: memories indistinguishable under the teaching requests have the same behavioral loss. Request selection therefore partly defines what capability is acquired. Reconstruction-only teaching does not exercise the later-question use contract; matching taught requests guarantees neither unseen-request behavior nor a unique memory representation. No additional theorem or benchmark is needed to state this.

The direct predictor G(x,r) must receive the same donor evidence and teacher responses. H's special restriction is that its export cannot depend on the later request r. Reuse can matter for known request families when particular questions arrive later; requiring an entirely unforeseen family would unnecessarily narrow the mission. Potential savings must credit the direct predictor with ordinary prefix caching too. Compact memory may reduce later attention work, but savings cannot be inferred from repeated uncached baseline calls. This carries S4.1/S19/S38/S42/S46 into the concrete consumer choice, rather than reopening those lines.

**Consumer-specific prerequisite, not the whole allocation.** Specify the multiple-request use and saved-text/direct-prediction alternatives before choosing a fitting objective. The live boundary additionally requires the retained prior operation A, new contribution B and useful joint use; memory reuse alone is insufficient. The acquired object is defined by distinctions recoverable under those requests, not by a coordinate norm. No new empirical block, local model loading or claim of a learned-space hole.

**Bounded competing-route question.** Before assembling a response predictor and context compressor, inspect CODI's direct continuous-reasoning distillation as one alternative consumer-preparation recipe. Does it already train a latent producer through final-answer behavior, what source/recipient access does it need, and which part, if any, can be reused for a new donor? A demonstrated complete trained recipe could replace speculative assembly as a reference comparator; same-query reasoning alone would not establish later-request memory reuse or cumulative acquisition. No reproduction or additional architecture search is selected.

**Competing-route result.** [CODI, EMNLP 2025 final](https://aclanthology.org/2025.emnlp-main.36.pdf), sections 3-4.4, trains shared parameters on explicit rationales and latent-answer generation, with detached pre-answer hidden-state targets linking the tasks. Stop-gradient does not freeze the shared teacher parameters. Table 2's no-alignment

arm retains explicit-CoT training, a stronger information-access control than answer-only training. The separate-static-teacher arm improves when explicit-CoT training is added to the student. Inference uses a configured latent-step count; the step-count figure varies training settings, not just inference time within one checkpoint. These are published trained-procedure comparisons, not locally reviewed generation quality or total-cost evidence. Independent reviewer: `intervention_value_review`. Root verified Table 2 in the final PDF; the reviewer's additional resource reading used author v3 Appendix A and is not promoted to an exact final-PDF resource claim here.

Root also inspected official [code revision 2c2314662c63e9f482ebc46614ffe9af17a241e5](https://github.com/zhenyi4/codi/tree/2c2314662c63e9f482ebc46614ffe9af17a241e5). `src/model.py:296-298` uses the same model for a no-gradient reference and a gradient-bearing reference pass. Lines 330-368 feed previous hidden states back and form detached alignment targets; lines 384-400 add the explicit-task loss. This verifies the access/update distinction, not a reproduction of Table 2. No source code was imported or executed. PDF and file hashes are in the ledger.

**Allocation consequence.** Use the complete trained continuous-reasoning recipe as a reference alternative to speculative predictor/compressor assembly. Preserve the no-alignment multitask control: removing richer training data is an inadequate test of the linking objective's contribution. A complete recipe can be useful without establishing which latent steps implement which operation.

The reviewer proposes fixed learned inputs in place of carried hidden states as the cheapest continuation control. Keep it prospective: equal slot counts do not mean equal runtime, and fixed slots may admit parallel prefill while recurrent feedback needs serial execution. Count actual computation and allow the direct implementation its efficient path. No new training run follows. This distinguishes an available trained reasoning procedure from an unverified portable memory; it does not settle donor acquisition, prior-use retention or separately prepared composition. The native target remains useful continuation and preservation under changed contexts, not hidden-coordinate agreement itself.

**Availability check before considering a bounded diagnostic.** Inspect only the official release pointers for a small already-trained continuous-reasoning model. An available small checkpoint could make a narrow useful-continuation question empirically accessible without training. Replacing recurrent states at inference would test dependence of that trained procedure, not replace the matched-training fixed-slot control above. If only training code or large checkpoints are offered, do not train a substitute, download weights or manufacture a new benchmark to keep this line alive. This is an interface-availability check, not an execution lock.

**Availability disposition and one training episode.** The official release does point to `zen-E/CODI-gpt2`, revision `fd641b3d3edc59e4f534b55588e906588c9e36bb`, advertising a 406,398,137-byte weight file. The base checkpoint is locally cached. Availability is not the blocker: reviewer `resumed_frontier_adversary` rejects an own-model feedback-ablation download as low leverage for acquisition. No weights were downloaded. A second dialogue

resolves the separate-donor dependency using the already pinned entrypoint instead.

`train.py:219-293` turns question/rationale/answer text into recipient-tokenized examples; `src/model.py:262-274` accepts token IDs, masks, labels and positions, not an externally supplied teacher model or hidden-target tensor. The reference states come from the changing shared model. External rationale/answer text can be prepared offline, and tokenization can be cached under fixed conventions. Reference hidden targets generally cannot be cached once across parameter updates without changing this objective. No-gradient execution is not frozen parameters. Reuse within an unchanged parameter state is narrower and not implemented here.

The inspected default entrypoint supplies no cross-donor layer/dimension map. That does not deny the paper's separate-teacher experiment or claim a search of every branch. It identifies what this released path actually offers: ordinary external text teaching plus dynamically produced shared-model targets. Independent round-two review confirms the distinction and closure. Stop this availability branch without more code search or a substitute implementation; retain its complete trained-recipe and no-alignment multitask comparison as research assets.

### S50. A concrete encoder acquisition episode: recognition and segmentation

**Episode to inspect, before source reading.** An initial segmentation system A produces spatial masks. A semantic recognition donor B contributes category/text meaning. A joint request asks which pixels belong to a named category, while the system must retain its earlier spatial operation and the donor's semantic use. Inspect SAM-CLIP as one proposed model-merging episode for those roles. Determine what is actually trained, retained and evaluated before adopting its claims. This is a prospective source contract, not a statement that every listed capability has already been demonstrated or that the merged model is available locally.

This targets a persistent encoder's before/after uses, rather than repeated queries about one saved response. It does not reopen S34's deferred image-generation and scene-evaluator proposal. No model loading, dataset download, segmentation benchmark or checkpoint diagnostic is selected. A complete useful merge may still require substantial training; acquisition cost and any original-task degradation belong in the result. A second donor addition remains a separate cumulative claim.

**Source result, not a local experiment.** [Final CVPRW paper](https://openaccess.thecvf.com/content/CVPR2024W/ELVM/papers/Wang_SAM-CLIP_Merging_Vision_Foundation_Models_Towards_Semantic_and_Spatial_Understanding_CVPRW_2024_paper.pdf), sections 3–4/Tables 1/5: SAM-CLIP distills semantic embeddings into a spatial backbone while replaying spatial masks. Training uses 40.8M images, head preparation, joint updates and optional resolution adaptation; this is not training-free. Box-prompt segmentation changes from 41.2 to 40.9 COCO mAP and 36.8 to 35.0 LVIS mAP. The semantic teacher is CLIP-L/14, while Table 1 compares CLIP-B; these are not actual-donor semantic-retention measurements. The donor image encoder is replaced at inference; its text encoder remains. Table 5 reports VOC mIoU 60.6 for the semantic head at 448px and 66.0 for both heads at 1024px.

[Author v4 appendix](https://arxiv.org/html/2310.15308v4), B/C: refinement consumes the coarse semantic mask and sampled points. The illustrated original-SAM comparison receives the points. The direct proposal/classification pipeline uses

CLIP-B and reports 27.2 VOC mIoU. Neither comparison isolates the merger from all prompt, teacher and resolution differences. No second acquisition is reported. Root manually inspected published Figure 3 and Table 1 crops to check the source; this is not local output-quality evidence.

**Operational interpretation.** Let the existing operation be $A(x,g)\to m$: image plus geometric prompt to spatial mask. Let the acquired operation be $B(x,t)\to\tilde m$: image plus category request to a semantic mask estimate. The joint operation feeds $\Gamma(\tilde m)$, containing a coarse mask and points, into the spatial refiner. These symbols describe callable behavior, not presumed isolated capability regions. The meaningful new ability is selecting and refining what a category refers to in an image. An instance mask and a mask covering every instance of a class are different requests.

The existing operation now encounters prompts produced by the new operation. Its adequacy on old geometric prompts cannot settle adequacy on this new prompt distribution. Conversely, failure on the new distribution would not erase old-task retention. This is S5/S8/S13's contextual support requirement instantiated in a real acquisition episode, not a new abstract theorem. The native object is the meaning and legal continuation of a selection, including its spatial granularity; cosine distillation is scaffolding and does not supply that operational law.

**Decision-changing controls, not queued runs.** First compare the old and merged spatial refiners on exactly the same coarse masks and points from the acquired semantic head. This isolates refiner compatibility conditional on that head; it does not compare whole acquisition routes. Separately, use the actual semantic donor in a competent direct pipeline, and compare heads at matched resolution and adaptation. Report old-task degradation separately from the new joint benefit; neither zero degradation nor lower cost is required for every useful acquisition. Before a later C addition, retain the achieved A, B and joint behaviors as the reference, including requests generated by B. Ingredient-only replay is not an assurance that their acquired interaction survives.

**Allocation at selection, resolved below and continued in S51.** Adopt this as the concrete reference acquisition episode without local reproduction. The next question was preserving its new interaction during another admission using actual interfaces; the replay-source analysis below addresses that dependency. Independent source review by `intervention_value_review` used author v3; root checked final main text and v4 appendices separately. Final PDF custody: SHA256 `74d2b3bdb6e8ade5690f2a93a4a426b735716409b6ee6b5a5fa1b664b8177258`, 7,007,345 bytes, 13 pages; the final PDF does not include the author appendices.

**Matched-guidance interface check.** The [original spatial predictor](https://github.com/facebookresearch/segment-anything/blob/dca509fe793f601edb92606367a655c15ac00fdf/segment_anything/predictor.py) accepts both point prompts and a dense mask input, with the documented mask shape 1×256×256. Thus the original branch is not restricted to points-only by its API. The source comparison does not establish the matched-guidance result. A competent comparison must preserve image geometry, padding, logit conventions and mask selection, while each spatial path uses its own image encoder. Swapping only a

decoder onto the other backbone would introduce an unvalidated latent interface.
This closes the narrow expressibility check: no implementation hunt or execution follows. Predictor custody: revision `dca509fe793f601edb92606367a655c15ac00fdf`, 11,649 bytes, SHA256 `ab66c29ac0b5b204d23997ef49d8a2476f71b596ce97e35efbf116cfc2118fce`.

**Replay-source decision (worked proposal, no training).** The two-round approach review by `resumed_frontier_adversary` rejects another generic retention checklist. Instead compare replaying the original spatial/semantic teachers with replaying those teachers **plus the achieved joint service** during a later admission. This concerns an admission that modifies shared parameters, the consumer or another dependency of the achieved service. An unchanged isolated connected extension does not create parameter forgetting merely by adding a donor.
The first protects ingredients on their respective training inputs. The second can directly teach an interaction that became available after the first acquisition. Neither its necessity nor its benefit is established here.
Ingredient replay on original/native inputs also differs from ingredient replay on inputs generated by the acquired operation. If compatible component behavior is already adequately preserved on the induced support and the composition rule stays fixed, final-service replay need not add a necessary protection.

The concrete service has a further dependency: its final pixel labels compare scores across a requested class vocabulary, not just an isolated category. Write $J_0(x,V;\omega)$ for the achieved AB segmentation on image $x$, vocabulary $V$ (including its background convention), and point-sampling randomness $\omega$. Preserve text-template aggregation, preprocessing and output conventions as part of that request. A replay record can contain $((x,V,y_0)$, where $y_0=J_0(x,V;\omega)$, plus sampling provenance. The new system receives $(x,V)$ and must generate its **own** coarse masks, prompts and refined output. Feeding it the old coarse mask instead tests a conditional continuation only.

The existing unlabeled image pool supplies candidate $x$, but the image-level semantic distillation loss does not itself supply a distribution over $V$.
Class names can be chosen without new human mask annotations; choosing the query support is additional preparation, not an automatic property of the images.
Use declared training images and request families, with evaluation held out for the intended generalization claim. Retaining one fixed vocabulary does not establish retention under arbitrary categories or vocabulary changes. Absence/background cases and a mask with no point above the sampling threshold need an explicit service convention before target generation; no source failure is inferred.

A possible additional target loss is pixel cross-entropy $\mathbb E_{(x,V)}[-\sum_u\log p_\theta(y_0(u)\mid x,V,u)]$, where $p_\theta$ uses the updated system's final class scores before hard argmax.
This is ordinary pseudo-label distillation proposed for the complete service, not a new native law or a guarantee that the recipe works. Hard point selection can interrupt gradient paths: final loss does not automatically teach every internal decision. A differentiable coarse-mask path, a separate intermediate

target or another learning procedure would need an explicit choice before fitting.

One cached mask represents one sampled outcome, not the full stochastic service. Declare a deterministic reference and student sampling policy, or target an expectation/distribution over their randomness. Ordinary within-system sampling variation belongs beside any claimed degradation. Independent proposal review by `alignment_contribution_review` also identifies the cheapest training confound: extra joint targets provide extra optimization work. An equal-total-budget ingredient-replay arm is needed before crediting joint-target content for a gain. Matching final targets preserves behavior on that support, not internal mechanism.

Frozen AB targets can be generated once on a finite declared replay panel and stored; or AB can be retained as an online teacher. Charge target generation, teacher storage/runtime, student work and any repairs separately. This is a training dependency, not proof of donor retirement for the deployed service. Teacher outputs preserve achieved behavior, including errors; verified corrections must remain possible under the earlier S32 migration policy. Measure actual task quality and degradation separately from agreement with the teacher.

**Resolved boundary:** protecting the achieved interaction is expressible without new human segmentation labels, conditional on access to the trained AB system, images and a deliberately selected request distribution. The image-only recipe does not already contain that request coverage. No C capability, replay panel, loss implementation or training run is selected. The remaining investment question is which useful next contribution would expose a consequential retention tradeoff, not whether another generic replay framework can be written.

**Bounded sequential-learning comparator.** A three-query independent search found no qualifying third-donor semantic/spatial acquisition episode; this is not an absence claim. The one primary candidate inspected, [Select and Distill, author v2](https://arxiv.org/html/2403.09296v2), sections 3–4, adds labeled classification tasks sequentially. It distills from both the original model and the most recent accumulated checkpoint using unlabeled reference images. It does not admit a new independent pretrained donor or evaluate semantic/spatial joint behavior. Retain its original-versus-accumulated teacher distinction as a concrete comparator. Its feature-discrepancy selector is a heuristic; discrepancy is not itself evidence that a previous useful operation should be preserved or that a target is correct. The search ends here, without extending the catalog or selecting its training.

## S51. Candidate third operation: depth-conditioned semantic selection

**Question before source inspection.** Could a relative-depth donor C add a useful selection operation to S50's established semantic/spatial service? The intended benefit is to select visible category pixels on the near or far side of a declared reference, while retaining the earlier spatial prompts and semantic masks. This is a candidate use, not a selected architecture or a claim that C adds information absent from AB. A competent direct combination of the existing semantic mask and depth readout is the first rival method, and could itself be useful connected growth. No fusion training, downloaded weights, dataset or model run is selected.

The first task is to define a meaningful request without assuming extra instance grouping, metric distance or occluded geometry. A category mask can contain several objects; one average depth does not turn it into a well-defined object relation. Inspect the actual depth interface and its ambiguity before proposing a latent map. Continue this candidate only if its added operation and retention dependency can be stated through available outputs. Otherwise pivot from C, keeping cumulative acquisition as the objective. This does not reopen S34's image-generation proposal.

**Selected request for this source check.** Depth-selective photo editing: “select the visible tree pixels behind this marked foreground point.” This asks for pixels, possibly from several trees. It neither groups instances nor assigns a single depth to an entire object. The two-round `resumed_frontier_adversary` dialogue accepts this use and provisionally favors direct connected composition.

**One depth interface checked.** [Depth Anything V2, author v2](https://arxiv.org/html/2406.09414v2), section 5.2, describes affine-invariant inverse-depth output. The official `depth_anything_v2/dpt.py:187-221` returns a raw floating H×W map after whole-image aspect-preserving preparation and bilinear interpolation to the original image dimensions. `run.py:59-65` instead normalizes, quantizes and optionally colorizes a visualization. Use the raw callable result for comparisons. DA-2K's point-pair annotations assess within-image depth order; they do not supply semantic-mask quality or this project's joint acquisition result.

For the declared inverse-depth orientation, write the explicit rival operation as

$$
N(x,V,c,p)=\{u:J_{AB}(x,V)(u)=c\;\text{and}\;d_C(x)(u)<d_C(x)(p)\}.
$$

Here $p$ is the user's marked pixel, not an estimated object's center. Both outputs must be restored to the same original image grid with their actual preprocessing conventions. For $a>0$, replacing the entire field by $a\,d_C+b$ leaves this ordering unchanged. Independently rescaling crops would not provide this common comparison. Ties or invalid values need explicit handling; a raw numeric gap is not a calibrated uncertainty estimate or a metric distance. Approximate quality gates require task evidence, not an exact order certificate.

This establishes expressibility, not accuracy. Boundary interpolation, semantic mask errors and reference-pixel ambiguity remain consequential. The set intersection and affine invariance are ordinary scaffolding; the native object is a usable category/depth selection and the earlier operations that survive adding it. An explicit connected route is a legitimate candidate for growth. Assimilation needs an identified reason to replace that route, such as useful quality or resource improvement; no such comparison has been measured.

**Dependency check selected before the disposition below.** Determine whether the specific achieved AB system from S50 has an accessible checkpoint and a callable text-to-mask path. If it does, assess a complete AB+C feasibility episode. If not, close local execution consideration for this particular reference; do not construct a substitute AB and inherit the paper's retention claims. A standalone C inference would not resolve this dependency and is not selected.

9,904 bytes. Source code was read, not imported or executed; no weights downloaded.

**AB endpoint disposition.** The checked final paper, author arXiv record and [institutional publication page](https://machinelearning.apple.com/research/sam-clip) do not identify a trained checkpoint/callable release. Two focused endpoint searches did not bind one. Same-name repositories found include a different medical paper and an explicit separate-model pipeline; neither supplies the reviewed merged AB. This is a bounded unresolved-access result, not a claim that no release exists. Close local execution consideration for this exact S50→S51 episode now. Retain its use definition, source result and operational constraints. No author contact, substitute training, standalone depth demonstration or extended checkpoint hunt.

**Pivot boundary.** An available combined encoder could support a different acquisition episode, but its own existing operations and retained behavior would need evidence. Do not inherit S50's claims or choose it solely because weights exist. The next approach review should decide whether that substitution materially advances the mission or whether a different operation/use is more consequential.

**Fresh periodic approach review, 2026-09-14 around 15:30 UTC.** After consolidation at `62f85fe` and a separate entropy check, `s51_fresh_frontier_audit` recommends continuing the mission while rejecting another substitute-model search as the next priority. It identifies the distinction between extension without changing established computation and extension through shared modification. Under unchanged dependencies, requests, preprocessing and execution policy, the former has no parameter-forgetting mechanism. A changed user-facing route can still change behavior. This is independent subagent review, not a real CLI audit.

The review also distinguishes original-input ingredient replay from replay on B-generated inputs. S50's proposed joint targets may be useful, but are not a necessary extra ingredient if component preservation already covers the induced support. Six local probe blocks, fifteen scored forwards and 1065 apparatus /0 artifact-bearing lines remain unchanged; the ratio has a zero denominator. No literature result is counted as a built acquisition artifact.

**One explicit failure, worked before another endpoint choice.** In the photo-editing use, suppose the semantic mask correctly includes thin background tree branches, but the depth output blurs nearby foreground values into them. The direct intersection then omits branch pixels that should be edited. This is a hypothetical component error, not a measured failure or an intrinsic latent-space hole.

The cheapest repair hypothesis is to preserve the semantic boundary while refining

the depth field using the existing mask and raw image. Shared representation training is not needed merely to express such a repair. Its danger is equally concrete: a category mask can contain near and far surfaces, so assigning one depth to every connected category region can fabricate the desired result. A repair must preserve genuine within-category depth changes; fixed morphological filling or category-wide averaging is not automatically adequate.

If hard outputs omit useful uncertainty, first consider retained class scores, the raw depth field and ordinary image evidence already available to a direct consumer. Intermediate features could make a competent repair cheaper or easier to learn, but this example does not establish that advantage. A direct learned consumer is a serious comparator too; its learning and inference work must be charged alongside any shared adaptation. Distinguish an image-grid mismatch, an insufficient request definition and an actual inference error before attributing anything to latent incompatibility.

**Decision from this failure analysis.** No defensible shared-adaptation benefit has yet been demonstrated for this use. Retain direct connected composition as the expressible candidate; its empirical quality remains unmeasured. Do not invent shared updates to manufacture forgetting, build a repair module, or substitute models simply to keep this episode executable. The next substantive acquisition question should identify the useful limitation of leaving computations separate before choosing another checkpoint or training recipe.
This calls for a specific testable benefit hypothesis, not demonstrated superiority as a prerequisite to exploration. A bounded experiment may establish or refute that hypothesis; the hypothetical failure above alone does neither.

The review follow-up endorses cumulative assimilation of fresh-input operations as the next question family. It must identify the already acquired first operation, the second donor contribution and retained joint uses; no new training or model selection follows automatically. If ordinary teaching performs equally well, accept that route. If removal breaks adequate service, favor connected growth for that operation. This keeps the useful cumulative object central without making donor retirement or latent-specific superiority a universal mission gate.

## S52. Assimilating a consequence versus matching isolated answers

**Definition and question before dialogue.** In S42's proposed shared frozen predictor, independently learned donor ports need not modify previous ports. Assimilation therefore need not create shared-parameter forgetting either.
Its open question is useful fresh-input behavior after teaching-time donor removal, not an obligatory interference test. S49 already identifies the missing connection between response prediction and a competent later-question memory consumer; do not rediscover that dependency or reopen the closed checkpoint branches.

For this branch, distinguish two objects. A single predicted answer serves its request. A predicted consequence is meant to represent one analysis that remains usable under several later requests. Let a donor produce analysis $Y$ for input $x$, and let $K(Y)$ be its prepared consumer memory. S49's proposed response

loss matches consumer behavior under a request distribution. Ask whether that objective protects the **joint later-use behavior** when the analysis is stochastic or the requests are chosen adaptively, rather than merely matching each question's marginal answers. This instantiates S23's existing joint-compatibility distinction; no new abstract counterexample or numeric apparatus is selected.

For a procedure analysis that selects one of two alternative prerequisites, later questions about each prerequisite must refer to the same selected analysis. It is not enough to reproduce each prerequisite's aggregate frequency across different analyses. This is a prospective coherence issue, not observed model behavior. A deterministic reference analysis removes this particular stochastic ambiguity; it does not guarantee the student uses its retained object consistently.

The cheapest relevant comparator keeps the donor's ordinary analysis text and uses the same declared consumer/question policy. Direct teaching also receives the same analysis and permitted request supervision. Any advantage of predicting memory must justify its teaching and recurring work, with ordinary prefix caching credited to the direct route. No later request is silently given to a predictor that is claimed to produce its retained object before that request arrives.

**Decision sought.** Choose whether the intended service requires independent single-question performance, repeated questions about one fixed analysis, or an adaptive conversation that updates that analysis. These are different operations. Do not force the strongest contract onto every acquisition, but do not call marginal question scores evidence for a stronger persistent reasoning object. No task, consumer modification, training or model run is selected by this distinction.

**Loss calculation for the already proposed objective.** Hold the reference encoder and consumer fixed. Fix $(x,r)$, let $q_Y(a)=Q(a\mid K(Y),r)$, and define $\bar q(a)=\mathbb E_{Y\mid x,r}q_Y(a)$. For a student distribution $p$ with adequate support, expanding the logarithm gives

$$\mathbb E_Y D_{KL}(q_Y\Vert p) =\mathbb E_Y D_{KL}(q_Y\Vert\bar q)+D_{KL}(\bar q\Vert p).$$

The first term is independent of the student. Thus this per-request objective targets the marginal consumer distribution, subject to what the student's memory and consumer can represent. It does not by itself identify a shared latent choice across requests. This is ordinary KL algebra applied to S49, not a new native law or evidence of an actual trained failure. When requests depend on the donor's analysis, use $(Y\mid x,r)$, not $(Y\mid x)$; request selection can itself convey information about that analysis.

A leading question can consequently make memory appear useful or unnecessary for the wrong reason. Keep the same requests in memory-omission and ordinary-text controls; record whether the question policy used the reference analysis. Requests chosen after the memory is produced are not automatically independent of the answer. For adaptive later use, histories and request policy belong to the service; matching

isolated initial-question distributions does not establish that stronger behavior.

The task may accept any coherent valid analysis, rather than require reproduction of the donor's random choice among valid alternatives. Do not elevate exact joint distribution matching to a mission requirement. The practical next contract should preserve the consequential content/constraints across requested uses, allow valid corrections and distinguish coherence from factual or procedural correctness.

**Two-round review and adopted minimal contract.** `alignment_contribution_review` confirms the calculation and rejects a new correlation-preservation campaign. For the next candidate, favor a fixed consequence with objectively assessable answers to two independently supplied question types. Produce memory for a fresh case before revealing the question, then evaluate both uses of that same saved object. Different valid explanations or reasoning paths are acceptable. Report the paired case-level ability to support both uses, not an average that can conceal failure of one. This does not require adaptive state updates or arbitrary requests.

Donor responses are teaching evidence; correctness or an explicit admissible-answer criterion determines success. Marginal distillation may remain the training surrogate. A concrete application must justify retaining the predicted consequence against same-evidence direct teaching, saved text and any competent direct procedure. Do not choose a simple arithmetic toy merely because its labels are easy to check. No application or compute is selected here, and the broader cumulative question still requires a later donor admission and retention of earlier achieved uses.

**Resolved investment distinction.** Assimilation can grow independent learned ports over shared frozen computation; parameter interference is optional. A reusable consequence must be judged by its promised later uses, rather than coordinate matching or imitation of arbitrary donor randomness. The next substantive work is selecting a useful operation with this assessable contract, using actual teacher/consumer competence and serious direct remedies to determine whether an empirical probe is worth running. The algebra and contract are complete for this question; do not extend them into another proof framework.

**Simplest remaining confound for task selection.** Two anticipated questions can reduce to storing two predicted answers. Give the direct learner a joint output and an ordinary sufficient record, produced once and reused by lookup or computation; do not force it to repeat inference separately for each request. Two readouts alone do not establish acquisition of a reusable operation. A useful parameterized later use may make the distinction consequential, but a structured record that already supports it remains a valid acquisition route, not a disqualifying baseline trick.

### S53. Candidate operation: predicted products under later structural requests

**Candidate selected for source/data-contract study, not execution.** Independent `strategy_questions_review` proposes reaction-product prediction. A recorded mixed reactant/reagent input is mapped to a product graph before a later structural request is revealed. One request supplies a molecular motif; another supplies a candidate target structure. The retained consequence supports substructure or identity queries parameterized by that request, rather than storing two fixed

answers. This is a proposed analysis workflow, not a recommendation to perform any synthesis or a claim of experimentally validated chemistry.

The serious direct route predicts product SMILES once, parses and retains its graph, then uses ordinary graph operations. It receives the same donor teaching and gets its one-time prediction/parse costs credited. A latent consequence must have a competent reader; chemistry-specific embeddings do not automatically supply one. Study the small specialist precedent and its data conventions before assigning a recipient, choosing a benchmark or loading a model. Later acquisition and prior-use retention remain additional requirements of the cumulative program.

The first interpretation-changing checks are whether input preparation uses the withheld product to label reactant/reagent roles, which chemical distinctions the reference dataset retains, and whether graph identity agrees with the requested use. Agreement with a mined reference product is not necessarily experimental correctness. No source-reported generation accuracy is promoted to a local quality claim, and no reaction dataset, model weights or new runner is selected here.

**Source result and selected interface question.** [Molecular Transformer, author v2](https://arxiv.org/html/1811.02633v2), sections 2–4/Table 3, uses a 12M-parameter encoder–decoder and reports product prediction from mixed inputs. MIT removes stereochemical information; STEREO retains it. Mixed preparation avoids supplying the product-informed reactant/reagent split. The source documents missing inputs and questionable reference products. Its benchmark results are external precedent, not local generation-quality evidence.

The two-round direction review selects conditional access to a frozen reaction encoder as the next bounded question. This tests a needed reader before selecting assimilation. The decoder may perform essential reaction computation; a newly trained query reader could learn it afresh. The hypothesis is useful access to predicted connectivity, not that the encoder already contains a complete product graph. The donor encoder remains at runtime, so this would not itself be full donor retirement. Direct structured-product teaching remains an acquisition route.

**Workload correction.** Apply S4.1 to this specific choice. After canceling common encoder work, decoding/retaining a graph costs $D+P+n\,g$; conditional queries cost $n\,q$. Conditional access saves runtime only when $n(q-g)<D+P$, before consumer acquisition costs. If $q>g$, more queries favor the retained graph.
The reviewer explicitly corrected its earlier opposite suggestion. Avoiding full decoding is not inherently efficient, and no runtime quantities are measured yet.

**Eligibility before any model choice.** Reactant copying is the cheapest confound: many requested product motifs may already occur in the inputs. Changed-only queries introduce the opposite confound—the answer is then the complement of input membership. A useful source example should exhibit present→present, present→absent, absent→present and absent→absent requests where available. These are input/output predicate cases, not stereochemical or laboratory claims.

For the paper's Table 1 illustrative mixed reaction, a bounded graph-query calculation can check whether these cases occur using a declared fixed motif list. Expected: a carbon triple bond disappears, a longer saturated carbon path appears,

and unchanged-present/unchanged-absent motifs remain. If the list does not produce these cases, record that limitation without replacing examples to force a pass. The confound is mistaking queries on the recorded product for learned reaction prediction: this exercise tests eligibility and the direct reader only. It requires no donor, weights, training, chemical simulation or benchmark expansion.

**Source illustration, manually checked.** Root and `strategy_questions_review` trace Table 1's mixed-input/product SMILES and obtain the following predicates:

| Connectivity request | Input mixture | Recorded product |
|---|---|---|
| Contains a carbon–carbon triple bond | Yes | No |
| Contains an eight-aliphatic-carbon path joined only by single bonds | No | Yes |
| Contains a six-membered all-carbon aromatic ring | Yes | Yes |
| Contains a fluorine atom | No | No |

The source branch `CCCCC#CCCO` has a triple bond between its fifth and sixth carbons; the product branch `CCCCCCCCO` has eight single-bond-connected carbons. Including the external benzylic carbon extends the product path to nine, so the request says **contains** an eight-carbon path, not that eight is its maximum. This manual source calculation establishes an illustrative four-case distinction, not a useful learned predictor or benchmark. Constant answers would solve this single example. RDKit is absent from the default Python environment; no package was installed, no parser was executed and no new empirical block is counted.

**Adopted next boundary.** The source example licenses further task-contract work around reaction-sensitive connectivity, not training. Keep unchanged as well as changed requests, and match their input-membership status before interpreting query success. Explicitly define identity under the chosen dataset conventions; MIT cannot establish stereochemical identity, and equivalent serialization does not license arbitrary tautomer, charge or fragment normalization.

The next decision is a deliberately limited consumer and attribution comparison: can a limited reader use the frozen reaction encoder's states to answer these later requests, beyond input-only and untrained-feature controls, at worthwhile total effort against decode-once graph queries? Reference-product graph queries verify the task answers; they do not validate the different latent interface. Training that reader is additional chemistry learning unless controls show otherwise. No checkpoint substitution, dataset expansion or execution is selected automatically. The native target is stable consequence identity under changing requests; graph operations and neural readouts are scaffolding, not a newly demonstrated latent law.

**Consumer attribution correction (independent two-stage review).** Let a mixed reaction input be x, a later motif request be r, and its reference-product predicate be a. Compare one declared conditional reader class h(F(x),r), trained separately on identical reaction/request labels and budgets, using (i) frozen pretrained contextual states, (ii) input token/position features before contextual computation, and (iii) frozen random contextual states of the same architecture/tokenizer. Match token access, masks, truncation, query encoding and reader capacity. A fixed

training budget compares accessible performance at that budget; it does not prove that every feature arm reaches its best possible performance.

An explicit graph exposes bonds and atoms that contextual token states do not. A graph-query procedure is therefore an answer-construction check, not a positive control for the neural reader. Encoding product-only strings also changes the input distribution; learning a graph-to-state bridge adds another learned task. The native donor's decode-once graph route is the deployment comparator, with its own prediction errors and generation failures. Reference graphs are not an oracle available to either prediction route at inference.

Keep every request for a reaction in one split, and check duplicate reactions and equivalent input serializations across splits. Generalization to fresh reactions with familiar motifs differs from generalization to unseen motifs or compositions. Any benefit licenses useful accessibility to this reader, not localization of reaction computation inside the encoder: the reader may learn transformations from features that pretraining organized well. A negative locates a limitation of this interface and learning budget, not an intrinsic impossibility of reasoning.

**First workload and access boundary.** The reviewed first comparison has one late motif request per fresh reaction; save the encoded state before revealing that request. This is conditional access, not evidence of consistency across multiple requests. Sample requests independently of withheld products and report the four membership cells afterward, including sparse or empty cells. Do not balance them using product labels. Include motif-frequency and input-membership baselines. The one-query runtime condition is $q < D+P+g$, with consumer learning and feature preparation charged separately. Set the accuracy/cost tradeoff before execution; no numerical advantage threshold is declared by this source check.

A bounded check of the [official repository](https://github.com/pschwllr/MolecularTransformer) found mixed-input training/preprocessing instructions, a regex tokenizer, and links to tokenized splits and averaged checkpoints. Its documented environment is old (Python 3.5, PyTorch 0.4.1, torchtext 0.3.1). Preprocessing removes from the product any molecule also present unchanged in the inputs: product predicates therefore refer to the benchmark's retained product, not every substance in the vessel. The mixed inputs lack the separated atom-contribution role token; this does not make target construction free of product-dependent conventions.

The linked data/model Box endpoints could not be inspected by the web tool; opening their explicit redirected URLs also failed. The GitHub revision metadata request returned HTTP 504. These are access observations, not evidence the files are absent. This check did not bind a checkpoint size/hash, repository revision, prepared-data sample or current execution compatibility. No weights, full dataset, packages or model code were downloaded/executed. Stop this bounded access check; do not turn it into a legacy-environment repair or substitute-checkpoint campaign. Execution is deferred, while the conditional-access comparison and its attribution limits remain usable. Further strategy should resolve a consequential question rather than add more contract machinery for this currently unbound local episode.

## S54. Admission history: endpoint stability versus retaining earlier use

**Question before source inspection.** Return from S53's single-reader precursor to S13's existing order question: does adding C require adapting to the acquired A/B system, or can retained preparation support an economical incremental update? The denizen cares about executable uses after acquisition histories, not equality of final coordinates. Independent two-round review selects one sequential-merging source with shuffled admissions; no new order theory or checkpoint search.

**Bounded primary evidence.** [Merging on the Fly, final NeurIPS 2025 paper](https://papers.nips.cc/paper_files/paper/2025/file/7611a3cb5d733e628081431445cb01fd-Paper-Conference.pdf), sections 3/4/6.1 and Appendices C/D, merges same-base vision experts sequentially, retaining fixed task heads. OPCM uses accumulated parameters, projections and scaling rather than replaying earlier experts. Ten shuffled orders use threshold 0.5. Table 1 reports small final-accuracy spread alongside negative backward transfer. Evaluation covers separate classifications, not a jointly composed use. Continual fine-tuning has one order; it is not an equally repeated order control. Task Arithmetic's coefficient is selected over a grid, so preparation differs.

Appendix D explicitly supplies streaming averaging and Task Arithmetic. Their constant-sized parameter accumulators undermine any claim that order independence requires retaining every expert. This is algorithmic parameter storage, not measured total deployment memory; the task-head bank remains separate. A coefficient chosen using the full task set is not prospectively calibrated admission of unknown tasks. Figure 12's stage matrices concern averaging, not OPCM. No local execution follows.

**Interpretation that changes the decision.** BWT subtracts each task's performance when admitted; shuffling changes those reference states and which last task is excluded. Thus BWT can vary even with the same final model. Small final-score spread establishes neither high quality nor retention. Compare fixed task endpoints for order effects, and each actual deployed stage for subsequent regressions; do not replace either with aggregate BWT alone.

This source supports a feasible incremental assimilation mechanism within a shared base family, not arbitrary grafting. It does not choose a joint-composition mechanism for us. Geometric orthogonality is scaffolding, not proof that a useful operation survives. The research choice remains whether a proposed shared update adds enough useful behavior to justify measured damage or repair of established uses, against retaining separate callable paths. Stop the one-source inspection; no source expansion, projection implementation or model-loading task is selected.

**Post-review allocation boundary.** Proposed repeats of S51's handoff trace and S42's prefix-reuse proposition were rejected after checking the live evidence. For the shared-predictor branch, the remaining decision needs actual second-donor teaching through an additional port, compared with a separate student at charged preparation and inference effort. First-port isolation is not that evidence. Record this empirical dependency once; another mask audit or generic proof does not resolve it absent a consequential eligible experiment. This narrows investment in that branch without closing the broader cumulative-acquisition program.

## S55. Empirical resources and a candidate editable interface

**Resource check before allocating compute.** The two historical vision-cache directories currently contain only their manifests, not feature arrays. Their old reported experiments remain historical evidence; they are not immediately runnable teaching packets. S43 and S47 remain closed. A two-query search for released aligned teacher/feature packets did not bind one. The inspected repository README at https://github.com/efkirmizi/distill/blob/main/README.md describes computing teacher features/logits into RAM during training, not a verified released packet. This limited check establishes no global absence, and small CPU preparation remains allowed; a preexisting packet is not a universal prerequisite.

**Definition before next source selection.** A candidate editable concept interface has a frozen image representation, interpretable attribute observations and a consumer whose decision changes under a declared attribute intervention. Ask whether a specialist's supplied distinction can become an operation the receiver uses, rather than merely another class score. Broad object recognition versus fine-grained bird distinctions gives a concrete possible use; arbitrary model diversity does not. An edit to a concept variable is not automatically a faithful intervention on the underlying image or latent cause. Competent recognition and useful intervention must be established separately, with direct classifier repair as a comparator.

**Source resolution and closed feasibility check.** [Post-hoc Concept Bottleneck Models, author v2](https://arxiv.org/html/2205.15480v2), sections 2/4, studies global class-concept weight pruning and renormalization. It is not the proposed local bird-attribute overwrite. The hybrid residual can retain effects bypassing concepts. The [official implementation](https://github.com/mertyg/post-hoc-cbm/tree/c0ba2b7b33b569cc713456cda8c25973809ec7cb) accepts concept scores through `forward_projs`; these are margins, not calibrated probabilities. Its README describes training the concept bank and classifier. The author-linked [reproduction](https://github.com/dgcnz/FACT/tree/b996ef039ca2167c8b1d89e4a2f1b5d4866c42c1) provides editing scripts; checked output directories contain placeholders rather than a trained consumer. No trained endpoint is bound by this limited inspection; this is not a global absence claim. No weights or datasets were downloaded.

**Acquisition implication.** A contributor may supply instructions for revising a response policy rather than new features or per-example answers. Applying an edit without optimization still changes weights. The edit needs held-out useful effects and collateral-behavior evaluation, and direct classifier repair receives the same feedback. A meaningful concept name does not establish faithful causal semantics. The original local-correction proposal remains untested; no model-specific native law is established. Independent strategy review accepts this narrower residue and rejects another scale counterexample as uninformative. Stop this artifact search. Small CPU preparation remains authorized when it serves a concrete new question; this check does not select training or demand another user confirmation.

**Next candidate, with a corrected teaching comparator.** Independent two-round strategy dialogue narrows a possible precursor to an explicitly requested species service added beside an established broad-object service. This is ordinary specialist teaching through frozen recipient features, not S42's trainable-suffix experiment or a claim of joint reasoning. Its useful question is whether specialist

supervision improves held-out species behavior under a limited label budget and
survives removal of the specialist at inference. Old-head isolation is bookkeeping.

An original generalist lacking the species vocabulary cannot supply a matched
species-teaching baseline. Compare the same recipient features, head capacity and
training-image pool with (i) the declared ground-truth label budget, (ii) those
labels plus specialist distributions, and (iii) those labels plus specialist hard
pseudo-labels. Additional unlabeled-image supervision is intentional, not equal
information; charge its preparation. A fully labeled head is a separately costed
reference. Direct specialist execution remains a deployment alternative. Bind the
specialist taxonomy explicitly; restriction or renormalization cannot silently
turn unsupported labels into model errors. Split evaluation images before fitting.

The initial dialogue allocated one bounded resource-feasibility check, not an open
model catalog. The completed check and subsequent allocation decision are below. At allocation, it needed a small trained species-prediction port, its vocabulary
and compatible evaluation images; the S55 editable-consumer lookup stayed closed.
The check was limited to that prediction role, with a small CPU sample allowed.
No run or acquisition result was selected by that initial allocation.
The head is ordinary mathematical scaffolding; any native-math contribution must
come from subsequent evidence about useful acquired distinctions and their effort.

**Completed prediction-port check; execution declined.** The prediction resource
exists. The [model repository](https://github.com/osmr/pytorchcv/tree/80726b972e36b6569889f890f139227c27a5acba)
defines a 200-class, 11,279,112-parameter predictor. Its metadata binds the
[42,331,658-byte weight archive](https://github.com/osmr/imgclsmob/releases/tag/v0.0.344)
and expected weight checksum. No weights were downloaded. The official dataset
loader uses original class IDs minus one and its prescribed train/test flags;
its inherited preprocessing defaults differ from the S55 concept-code wrapper.
Neither default is a verified reproduction of the selected checkpoint's full recipe.
Do not mix those preprocessing paths silently.

The [dataset authors](https://www.vision.caltech.edu/datasets/cub_200_2011/) warn
that images overlap ImageNet. A recipient trained there cannot be described as
having never seen the evaluation images. This does not by itself invalidate a
matched teaching contrast, but limits novel-knowledge and clean-pretraining claims.
The official archive is 1.1 GB and was not downloaded. Two inspected hosting entries
contain only README metadata. A [third mirror](https://huggingface.co/datasets/anjunhu/naively_captioned_CUB2002011_train/tree/9d62b3e6ee89d21aa29bba934ec6061b050ba32f)
contains a 5,994-row image/caption dataset. A two-row metadata request confirmed
individual image URLs and species-name captions. No image bytes were fetched.
Its exposed schema lacks original image IDs; taxonomy order and split provenance
remain unbound. Captions are label supervision, not permissible image-only inputs.

Independent result review reverses the initial willingness to run this precursor:
resource availability is now credible, but useful continuation has not been selected.
Success would establish this teacher/feature/label combination, not transported
operations, S42 suffix acquisition or composition. Failure would leave feature
capacity, teaching budget and target quality unresolved. Therefore decline the

species-head run for the active frontier, retain the receipt, and do not spend more on its remaining taxonomy or split binding. This is an allocation decision, not a negative experiment or a prohibition on ordinary readouts in a justified joint use. The resource check adds zero empirical blocks, forwards or runner lines. The next allocation must address a useful operation directly; returning to S42 cannot mean repeating its completed cache proof or another generic teaching-target discussion.

### S56. Does a mapped feature transfer an executable operation?

**Question before source inspection.** Return to the user's capability-mapping ambition through a concrete proposed operation: making a correct tool call. Let R be an established recipient, D a trained tool-use donor, and C an adapter learned from their activations. An intervention is not fully specified by a feature name or direction: record which model supplies the feature activation, where it is written, and whether D is executed on each new request. A joint encoder C(h_R(x),h_D(x)) retains donor computation; a prepared recipient-only operation C_R(h_R(x)) is a different acquisition claim. Both may be useful.

Inspect one primary report of crosscoder-mediated tool use. The decision is whether its tested intervention transfers an executable behavior, merely changes formatting, or depends on live donor computation. Test the cheapest confound first: donor information entering through the crosscoder's encoder. Compare correct execution with valid syntax; inspect prompt/template controls and retained recipient uses before interpreting a feature as a modular capability. No new model run or generic sparse-feature harness is selected. Geometric dictionaries are scaffolding; the denizen needs a move with a demonstrated useful consequence.

**One-source result.** [Localizing RL-Induced Tool Use to a Single Crosscoder Feature, v1](https://arxiv.org/html/2606.26474v1), sections 3/5/6/7, distinguishes steering the already-trained tool model from reconstruction into the base model. It reports no format gain in the latter. The authors acknowledge an unoptimized prompting baseline and no fresh-sample confirmation of selected steering settings. Its reported behavior is not verified execution of requested tools. This source supports investigating behavioral modulation, not demonstrated donor-independent acquisition or a complete tool-use capability localized to one feature.

**Pinned implementation resolution.** In [sweep_eval.py](https://github.com/Antebe/model_diffing_crosscoders/blob/31a4d3ee09286f5b62536c99d1d399897304d7d1/sweep_eval.py), lines 531–538 extract both models' activations on each input before reconstructing both streams. This inspected path retains live donor computation. Lines 413–463 score membership in the offered tool-name list, using substring matching; neither intent, arguments, execution nor termination is tested. The two inspected result files contain aggregates, not per-prompt continuations permitting corrected grading. This is a limit on those artifacts, not a claim that no raw outputs exist elsewhere.

Independent reviewer `alignment_contribution_review` traces a decisive static counterexample: with weather and email tools offered, an email name receives the maximum score even when weather was requested and arguments/closing tag are absent. This is an analytical code trace, not a model output or measured failure frequency. It does not show that all observed gains are errors.

**Conditional write-port identity.** Let f be the already selected sparse feature vector, M the decoder mask, and d_i^B the recipient decoder direction. The decoded recipient is b_B + sum_i f_i M_iB d_i^B. For a donor-exclusive i, the inspected mask has M_iB=0. Scaling any such f_i, using valid nonnegative feature indices, after feature selection cannot change that decoded recipient. This is an exact implementation diagnostic, not an all-or-none verdict on learned behavior. Re-selecting features, changing the mask or teaching a new recipient direction would define different operations.

The corresponding code scales post-selection features and decodes the recipient; the paper's strong targeted-steering result instead concerns the tool-trained model. Do not confuse that within-model intervention with the zero-write path. The encoder does not reapply its stored input mask at encoding; the exclusive label alone therefore does not establish donor-only feature input. A mapping can reveal a donor-associated distinction while deliberately providing no recipient write port for it. Shared reconstruction can still affect recipient behavior and can still carry live donor information.

**Allocation consequence.** Capability mapping remains a useful research route, but nominate a usable read/write operation before adopting a feature's name as a graft. A bounded future comparison must measure requested actions and keep the prompting remedy, donor runtime and recipient-only alternative explicit. Do not reproduce the offered-name metric, build a zero-mask toy, or launch this large model pair. No new local probe, forward, training or runner line. No native law or intrinsic latent-space hole is established by this source inspection.

### S57. Can a prepared map transport an independently discovered intervention?

**Question before source inspection.** S56's zero recipient write is one design, not a general obstacle. A constructive alternative fits coefficients c for an independently discovered donor direction v_D in a prepared donor dictionary and uses the corresponding recipient dictionary to obtain v_R. If this preparation is completed offline, adding v_R during recipient inference need not run D. The denizen's test is preserved useful response to the move, not vector fit alone.

Inspect one primary cross-architecture mapping report for the actual transfer recipe, its interventions, preparation and comparator. Ask whether it provides a recipient-only intervention, whether the behavioral evaluation supports more than selected examples, and which additional operation or donor the same preparation was tested on. S48 already distinguishes a direction from a full read/write clamp; do not repeat that algebra. No map fitting or model loading is selected.

**Constructive source resolution.** [Cross-Architecture Model Diffing with Crosscoders, v1](https://arxiv.org/html/2602.11729v1), sections 3.1/B.4.5/C.3, uses the ten shared donor decoder vectors most cosine-aligned with an independent persona direction. Their similarities weight the corresponding recipient vectors; the result is rescaled to the donor vector's norm. This is not least-squares fitting. The recipe permits offline preparation followed by recipient-only additive steering. The paper reports three persona transfers using the same prepared dictionary. These are selected behavioral illustrations, not a test of arbitrary directions,

useful new expertise, joint operations or successive donor admission. Dictionary training uses 100 million aligned activation pairs; cheap online application does not make preparation cheap. The authors distinguish representational exclusivity from absence of a concept. Source-reported examples are not local quality evidence.

The linked training repository is pinned at `8e8c0b3411144299ef89b1ea618483d706757c3c`; a bounded filename check did not locate a transfer/steering script. That is not evidence that the implementation is absent. No further artifact search, training or large-model reproduction is selected.

**What changes in our strategy.** S56's absent write direction does not force live donor use for every mapped intervention. A prepared shared dictionary can define a recipient-side move, with donor computation charged to preparation. Its empirical utility and coverage remain separate from mathematical expressibility. Reuse across several independently discovered moves is a relevant precedent and should receive credit even though it is not cumulative acquisition from further donors.

The next meaningful question is whether such preparation transfers a useful new operation more effectively than direct recipient preparation with the same allowed evidence. Do not substitute cosine fit or feature-name agreement for that contrast. Low similarity to each individual dictionary atom does not demonstrate novelty relative to their combinations. Existing R^n operations remain scaffolding; their success would need an operational law with tested scope to serve the native-math mission. No new numerical toy, model forward or runner is warranted by this reading.

Independent review confirms the method-level runtime distinction, not a traced execution implementation or measured savings. The separate stitching-based exclusivity test uses an affine feature formula; S48's displacement qualification applies there and does not refute the cosine-weighted transfer recipe. Keep these methods separate. Six local probe blocks, fifteen forwards and1065 apparatus/0 artifact-bearing lines remain unchanged.

### S58. Correct the precursor-selection criterion and test teaching

**Fresh approach review, before preparation or compute.** The independent `s51_fresh_frontier_audit` identifies a changed criterion in S55: the selected question concerned limited-label specialist teaching, but the later rejection required a consequential composition result. Correct that unrun allocation explicitly. This is not reopening a negative experiment or replacing the mission with classification. S56/S57 remain useful source evidence; a modest precursor may measure an acquired distinction without proving the whole cumulative system.

**Selected bounded contrast.** Use the already identified species predictor, one small fixed recipient representation, and the same image pool and head capacity. Compare label-only fitting, additional hard specialist pseudo-labels, and specialist distributions. Ground-truth evaluation labels stay outside fitting. The donor is absent from student evaluation. Report specialist performance, recipient label-only performance, paired differences and teaching/preparation cost. Do not use the generalist's incompatible class vocabulary as species targets.

**Expectation and outcomes.** Specialist targets may help where recipient features

already separate species but scarce labels fail to identify the boundary. A useful soft-over-hard difference motivates richer teaching signals; no benefit at this budget weakens this concrete recipe. Weak teacher predictions leave teaching untested. Neither positive nor negative result identifies an intrinsic latent law. The simplest confounds are taxonomy/preprocessing mismatch, leaked labels and unequal image access; bind these before fitting. Known pretraining overlap limits claims to images withheld from recipient fitting, not all historical pretraining.

Preparation is capped at 100 MB of model archives and 20 MB of image data, with no bulk dataset. CPU only, one compute job at a time, checkpointed batches; initial timing burst at most 30 seconds, subsequent compute blocks at most two minutes. Select the sample independently of model scores. Exact sample/label counts and hyperparameters must be frozen before scoring, with no test-driven expansion. The initial task is binding the existing resources and small sample, not a new model catalog. No measured result exists at this allocation checkpoint.

**Frozen implementation details before scoring.** Select six class IDs with seed 20260914; each supplies twenty original-training and ten original-test images. Use three labeled training images per class under label-draw seeds 0/1/2. Cache both backbones on this fixed 180-image panel. The recipient is pooled frozen MobileNetV3-Small; the teacher is the bound CUB predictor. Standardize on the 120 training feature rows only, with a floor for zero-variance coordinates. Linear six-way heads start at zero and use 200 Adam steps, learning rate .03 and mean squared-weight penalty .001. Teacher temperature is one, conditioned on the six selected classes. Supervised and unlabeled-teaching losses are each means and receive equal weight in teaching arms. Label-only sees the same images/features but no extra labels. A fully labeled head is a separately charged positive-control reference, not an equal-label competitor. Report training fit and each label draw; three draws still share only sixty test images. No test-driven tuning or expansion. Cache blocks have a cumulative 600-second wall ceiling including model startup; head fitting is capped at 120 seconds. Preparation is capped per attempt at ten minutes and resumes only the same frozen selection. Sources and pixel hashes are retained. The original archive returned HTTP403; an original-file-layout mirror binds labels, image IDs and original split flags without downloading the bulk archive.

**Preparation binding and review correction.** Frozen manifest SHA256: `1327e7e73049486e25e0891ac85990e8a9d6712f0578cdc6263fddb1111acef6`. The six classes are Hooded Merganser, Horned Puffin, Fox Sparrow, Black-throated Blue Warbler, Myrtle Warbler and Red-bellied Woodpecker. Their image paths agree with class IDs and all 180 IDs are distinct. The selected transform is shorter-side resize 256, center crop 224 and standard ImageNet channel normalization for both backbones. The teacher's release log pins training source commit `81ee358fa1049153d2a3837aa49391daf57008d5`; its validation defaults support these size/normalization choices. This is not a claim of bit-identical historical image resampling across frameworks. No preprocessing sweep is permitted.

Independent implementation review finds no fatal label/loss/indexing defect and requires an external deadline supervisor. The runner now records each attempted

compute process before launch and enforces import/load plus ready-state deadlines from a separate process; failed attempts consume the cumulative budget. Source package pytorchcv0.0.74 is isolated under internal/probe_dependencies; the existing Python environment supplies the tensor and image libraries. No global package installation or GPU allocation occurs.

**Completed result and independent audit.** On the same sixty original-test images, label-only heads score 52/49/52 correct across label draws 0/1/2. Hard teaching scores 59/59/58; soft teaching 57/52/55; the fully labeled reference 59/59/59. Hard teaching corrects 7/10/6 baseline mistakes with zero regressions. The repeated reference is deterministic, not three independent replications; all arms and draws share sixty test images. The full teacher scores 56/60 and the declared six-class restriction scores 59/60. Retained six-class probability mass ranges from .0288 to .9559 (median .6812).

The cheapest explanation is directly supported: restricted teacher hard labels equal ground truth on all 120 training images. Each teaching draw supplies correct labels for 102 images beyond the eighteen human-labeled examples. The full-label reference confirms adequate readout capacity. Its uniform weighting differs from the teaching arm's equal labeled/unlabeled loss weighting; their small difference does not establish extra teacher information. Soft distributions offer no advantage over hard labels under the locked recipe. No temperature/loss sweep is selected.

Independent tool-assisted reviewer `cache_integrity_review` verified metadata and image hashes, disjoint IDs, train-only normalization, reproduced label draws and every saved test prediction using only cached tensors and saved heads. This is not a real CLI audit. Root inspected three error/correction images (IDs 5199, 9356, 10044); this visual check does not replace dataset labels or constitute expert species relabeling. Exact train/test image hash overlap is zero, while historical pretraining overlap remains unresolved.

**Licensed result:** correct specialist pseudo-labels improved a linear head over frozen recipient features across three scarce-label draws without teacher access at student evaluation. This is useful ordinary teaching, not new backbone knowledge, native latent law, soft-information advantage, cumulative acquisition or general cost superiority. Label scarcity was an obstacle; an intrinsic representation hole was not demonstrated. Conventional feature standardization and linear heads are R^n scaffolding. The native target remains useful distinctions that survive provider withdrawal and remain available when further operations or alternatives are added.

Preparation completed in 285.14 seconds with 18,850,762 image bytes and 52,638,209 model archive bytes. Three externally supervised compute attempts completed in 34.95 seconds total: two cache processes, 360 image-level backbone evaluations, then twelve heads with 2400 optimization steps. Backbone forward time totals 13.1144 seconds; timing scopes are retained separately. No GPU. Only attempt-log redirection changed between the first four and remaining 176 cached images. Final runner has 286 apparatus lines; candidate heads exist but no reusable acquisition component was built. Session totals: seven scientific probe blocks, 375 backbone evaluations, 1351 apparatus / zero artifact-bearing code lines.

The strategy mandate does not require construction to improve that ratio.

The reviewed next investment changes the acquisition question rather than tuning this nearly saturated panel. Its frozen sample and completed result stay closed.

### S59. Admission changes the choice set

**Denizen question and proposed decision.** Can an acquired species distinction remain useful when new alternatives are admitted, without the caller first telling the system which contributor applies? The so-what is: learn another specialist's distinctions while still knowing when to use what was learned before. Independent direction reviewer `alignment_contribution_review` proposes successive vocabulary admission as a next precursor. Using the same specialist for another group would be one-provider vocabulary acquisition, not multiple-donor acquisition.

**Apply existing mathematics, do not rediscover it.** S39 already shows that conditioning on a subset erases its probability mass; S42 records vocabulary normalization effects, and S50 treats vocabulary as part of a request. Let A and B be disjoint class sets, with scoped readouts q_A(y|x) and q_B(y|x). A union service also needs a scope probability g(x). Its probabilities are g q_A on A and (1-g) q_B on B. The scoped readouts alone do not determine g. This is an interface obligation, not a new theorem or proof that learned representations are deficient.

For a true conditional law p on the union, write pi(x)=p(A|x). The conditional log-loss excess of that factorized service decomposes exactly as

KL(p || q) = KL(Bern(pi) || Bern(g))
+ pi KL(p(.|A) || q_A)
+ (1-pi) KL(p(.|B) || q_B).

This follows by substituting p(y)=pi p(y|A), or its B counterpart, in the KL sum. Terms with zero true group mass are omitted. Thus useful scoped prediction and scope selection are separately measurable contributions; exact scoped retention does not guarantee useful union choice. Conversely, a union argmax can change after alternatives are added while the original scoped service remains unchanged. Specify which request is promised before calling this forgetting.

**Candidate comparison, not an allocated run.** Freeze the achieved A head; teach a B head and a group selector using permitted training labels and cached features. Compare against a jointly taught union head with the same evidence. Group labels derived from permitted training species labels are legitimate; test group identity is not an input. Full specialist logits may serve a separately charged teacher diagnostic, not free recipient routing. Test both the original scoped request and mixed union requests. Never compare head maxima as though separately normalized confidences already supplied calibrated scope.

**Allocation challenge.** At this small scale, retaining old feature rows and refitting one linear union head is cheap. Hierarchical classification may add machinery without a resource benefit. Fixed scoped heads trivially preserve scoped predictions; that fact alone is not informative empirical retention evidence. No artificial ban on old features or joint fitting should manufacture an advantage. Before another run, identify the actual quality, reuse or acquisition-effort

uncertainty that would change the choice. The broader mission does not require this particular hierarchy. This definition and second-round challenge precede any new data, fitting or sample expansion.

**Second-round resolution.** The reviewer agrees not to allocate this hierarchy comparison at the present scale. A union head can coexist with unchanged A, reuse the same backbone/features, and preserve the old scoped service too. Different classifier inductive biases could produce a small quality difference; that would not by itself answer a consequential acquisition question. Joint teaching while retaining the old scoped head is the reasonable implementation default if this vocabulary expansion is needed, not a theorem of accuracy dominance. Reconsider reuse only under an independently motivated workload with material accumulated preparation cost, or a contribution requiring an inadequately supplied computation. No new run, fitted head, model forward or apparatus. The conditional decomposition is an application of existing probability, not a new native law.

### S60. Learn a representation that supports further readers

**Question before an experiment.** S58 fits a useful terminal decision into existing features. A different acquisition target modifies the representation so that subsequently fitted readers can use several contributed properties. Define the retained object as the learned encoder plus declared adapters; distinguish an unchanged teacher consumer from a newly trained downstream reader. Credit the reader's training rather than attributing all resulting reasoning to the encoder. The so-what is: teach one representation from several specialists, then use it for questions not supplied as teaching labels. No large reproduction is selected.

**Bounded primary source.** [AM-RADIO, camera-ready v5](https://arxiv.org/html/2312.06709v5), sections 3–5, learns a student encoder through teacher-specific summary/spatial adapters. It matches features rather than labels; adapters are two-layer MLPs. Table 3's "None" removes spatial supervision, not all teaching. Adding both spatial teachers gives ADE20K 48.13 versus 47.05 for spatial DINOv2 alone, with summary teaching retained. Frozen-feature segmentation uses trained linear readers; VQA adds projector training and language-model instruction tuning. Existing CLIP and SAM consumers are also used without fine-tuning their decoder heads. Training reports 600,000 steps and 614 million examples; this is not a small preparation. Stage two adds SAM while also changing resolution. Figure 5 reports a feature-error mode change around 720 pixels, not a measured downstream failure rate.

**Interpretation after independent source review.** This is a serious constructive precedent for representation-level multi-provider assimilation beyond S58's head-only learning. It does not isolate repeated admission from other training changes, or establish retention after arbitrary future contributors. Downstream transfer deserves credit even when its task type was anticipated; chronological unanticipated-task reuse is a stronger separate claim. Cosine/feature matching is R^n scaffolding. The operational concern suggested by the resolution effect is whether a permitted change of presentation changes which contributed operations are available. Feature error alone cannot adjudicate that concern. No local model loading, new runner, parameter fitting or empirical block follows from this source.

Independent reviewer `alignment_contribution_review` read the final CVPR paper and confirms the frozen-encoder/new-reader distinction and spatial-ablation scope. The inspected main paper does not supply a matched ordinary output-teaching control. Continue: this is a useful positive precedent, not proof that matching representations always beats teaching outputs at equal effort. The next source question concerns coverage across presentation conditions and actual operation quality; do not substitute feature-error tables for behavioral evidence.

### S61. Separate presentation robustness from added information

**Definition before a local probe.** An acquired operation is promised on inputs and requests, not on a vector without its acquisition conditions. Let T change an input presentation. Call T admissible for request q only when the evidence needed for q is preserved. Then test the achieved reader's useful response across x and T(x), charging any reader repair separately. Higher resolution can reveal new evidence; preserving every output under every resize is not the objective. For requests that need those new details, usefulness should be measured directly. This applies the existing task-relative interface vocabulary, not a new invariant.

The immediate source question is whether S60's feature mode change corresponds to lost useful behavior and whether correcting teacher/input coverage repairs it. The simplest competing explanation is ordinary training support: different teachers were used under different input conditions. No intrinsic conflict among their latent spaces follows from that recipe. The inexpensive inference alternative is to retain an operation's working input size where the intended request permits it; compare its lost detail and cost before declaring new training necessary.

**Independently reviewed source.** [RADIOv2.5 v2](https://arxiv.org/html/2412.07679v2) section 3.1/Figure 2 reports zero-shot classification deterioration above roughly 512 pixels, beyond a feature-only diagnostic. Section 4.2 teaches each provider across resolutions, using interpolation or padded/cropped teacher inputs, and describes 900,000 training iterations versus the 600,000-iteration baseline. Table 1 A-to-B improves ADE20K from 50.03 to 52.84, but depth slightly decreases. Semantic heads are trained at three resolutions and the best reported (§5.1). VLM evaluation unfreezes the vision encoder during instruction tuning; it is not the frozen-encoder protocol of S60. These results support the repair approach, while leaving training-budget attribution and unchanged-reader retention distinct.

**Decision relevance.** We now have an operationally consequential source failure with a concrete constructive response, not merely colorful feature plots. The relevant acquisition object includes which conditions each contribution was taught under. The next mathematical question is how to specify useful extension across conditions without demanding invariance to genuinely new information. No local model download, run, new apparatus or change to S58's panel is selected.

Independent `alignment_contribution_review` confirms that Figure 2's classification test retains the language-side consumer, whereas separately fitted dense readers and vision-language fine-tuning measure other forms of usefulness. Reader weights need not be frozen as a universal rule: the retained capability is the promised

external operation, and permitted repair has a cost. Newly prepared benchmark readers do not measure retention relative to a previously achieved service unless that service is actually replayed. This applies S7/S13/S32 rather than adding a new retention requirement. No seed-level or matched-budget causal claim is made.

**Second-round decision.** Close this bounded source inquiry. For a future admission, reserve a bounded consumer-repair arm and judge prior achieved requests before and after permitted repair. An inexpensive repaired reader is a valid acquisition outcome; a fixed-reader failure alone does not reject the route. Another generic protocol elaboration adds little without a concrete admission.

### S62. Later questions versus retained terminal answers — completed bounded probe

**Question and definition before data binding.** Does retaining a specialist's internal representation allow useful later questions that its ordinary prediction interface makes substantially harder? Let z(x) be a frozen specialist feature, p(x) its full species prediction, and a(x) a separately annotated visible attribute. Compare equally budgeted readers of z and p on held-out attribute questions. Attribute variation within species is required for the main contrast; otherwise species recognition alone could explain the apparent new access. Include that identity shortcut and the existing recipient representation as direct controls. This is a task-relative value-of-interface question, not proof that logits contain no attribute information or that a learned reader invents no new knowledge.

The so-what is: keep a specialist's representation and ask useful questions later, instead of being limited to the answer it was originally trained to give. A pairwise attribute comparison could be a simple declared consumer, but is not automatically a reasoning-model breakthrough. Connected feature extraction and offline exports are distinct; cached features do not provide fresh-input access after the provider is removed.

**Candidate resources and selection limits.** Existing S58 models and images may avoid new weight downloads. Per-image attribute metadata and its uncertainty labels must first be bound. No attribute outcomes have been inspected, no attribute reader fitted and no additional feature extraction selected. Reusing a panel after seeing species results must be disclosed; this does not reopen or tune its completed species estimand. Independent direction review will decide whether this addresses the mission or merely repeats terminal readout work. No run is queued.

**Reviewed annotation-feasibility allocation, before selected-image labels.** Bind the fixed breast-color family, IDs 106–120, from the pinned mirror's root `attributes.txt`. Certainties 1/2 mean not visible/guessing; retain votes with certainty 3/4 (probably/definitely). This is annotation confidence, not verified visibility. Aggregate confident votes only when unanimous; conflicting confident votes or no confident vote yield unknown, never absent. Inspect original-training images only. With seed 20260915, shuffle sorted training IDs within each sorted species, then pair adjacent IDs without reuse. Freeze those pairs before reading annotations. Report every color/species, including zero qualifying comparisons. Qualifying comparisons require both labels known and different.

At least twelve distinct qualifying training pairs across at least three species licenses reader-design consideration; it is an allocation threshold, not proof of statistical adequacy. Multiple colors on one pair are not independent support. Test annotations remain unexamined. Failure closes this family/pair construction without a feature-capability verdict or attribute search. Independent reviewer `alignment_contribution_review` accepts this scope and aggregation correction. The 73,132,180-byte annotation file supports byte ranges; bound extraction to 5 MB and avoid the complete archive. No model compute is authorized by this gate.

**Completed training-support check.** The frozen manifest precedes ranged label extraction. It yields 26 distinct discordant training pairs across all six species (4/5/5/2/7/3 in class order), meeting the allocation rule. Extraction received 3,949,152 bytes in 21.62 seconds, with per-range hashes and all selected training labels retained. This is annotation preparation, not model evidence; no forward or fitted reader occurred. Test attribute labels remain unexamined. Exact receipts are in `experiments/results/attribute_comparison_v1/`.

**Prospective reader-design proposal, not yet execution authorization.** Retain all 200 raw teacher logits as the primary terminal-output comparator, not just the winning label or six-class restriction. Compare pooled teacher features and cached recipient features, with class-identity shortcuts as diagnostics. Larger feature dimension must not silently grant unrestricted reader capacity. One candidate is ridge readers with train-only standardization and matched effective degrees of freedom, selecting regularization from the training feature spectrum rather than attribute outcomes. A shared intercept and separately counted feature/storage costs remain necessary. Such matching compares a declared accessible reader family; it does not test every possible decoder or establish information-theoretic absence. Direction review must settle this budget before any teacher-feature extraction.

**Execution design approved after review, before test annotations.** Use linear ridge readers of full raw 200 logits, pooled 512 specialist features, and cached 576 recipient features. For each attribute, use identical confident training rows across arms, center and standardize on those rows only, and match slope effective degrees of freedom to min(15, minimum numerical rank across arms). Rank tolerance is 1e-10 times the largest training Gram eigenvalue in float64. Add a free intercept; rank-zero or single-valued targets receive constant scores. Find regularization from the feature spectrum alone, including the zero-regularization pseudoinverse limit when needed. Report achieved degrees of freedom and regularization. This controls one complexity measure, not all expressive power or inductive bias.

Freeze disjoint original-test pairs by the same sorted-species/shuffled-ID procedure with independent seed 20260916 before extracting their labels. Score known, discordant colors by comparing continuous predictions, with exact ties worth .5; average colors within each pair. Report paired feature/output wins, losses, ties, mean score difference, support and species breakdown. No arbitrary success gate, attribute selection, hyperparameter sweep or confidence claim from pair–color rows.

Authorize at most 180 CPU specialist forwards to cache pooled features, reusing all prior recipient features and raw logits. Verify reproduced logits with

atol=1e-5, rtol=1e-5; a mismatch blocks interpretation until resolved. External process deadlines: 120 seconds feature extraction and 120 seconds fitting, with attempt receipts before launch. No GPU or new weights. Annotation extraction is separate bounded preparation; raw selected votes must be retained for custody. Independent `alignment_contribution_review` approves this bounded probe, not any broader reasoning, intrinsic-information or cumulative-acquisition claim.

**Custody completion.** Independent `cache_integrity_review` reproduced all fixed pairs and support counts, then verified all 1800 retained training votes against the aggregates: 1440 known, 360 unknown, zero mismatches. Each image–attribute has one vote, so unanimity is vacuous on these records; confidence filtering does not establish inter-annotator agreement. To preserve raw-vote evidence, six previously hashed ranges were re-fetched (an additional 3,900,000 bytes / 1.586 seconds after the initial feasibility check). Combined annotation acquisition is 7,849,152 bytes; this supplemental custody action is separately charged, not hidden inside the initial 5 MB allocation. Only selected training votes are retained; fetched ranges can contain neighboring records that were discarded without label analysis.

The frozen `design.json` SHA256 is `26dae188c82606b88ae28f97222e495bac479ae622922e6684a756e38792f6b7`. It fixes all thirty test pairs before their attribute labels are extracted. Next: implement one bounded runner, retain selected test votes, extract at most 180 specialist feature packets, fit the fixed readers, and independently audit the result. No code or model execution is represented as completed by this checkpoint.

**Completed result, independently reproduced.** The frozen thirty test pairs yield fourteen qualifying disjoint pairs and 31 color questions. Mean color-question scores within each pair, then means across pairs, are:

| Retained input to prepared reader | Mean pair score |
|---|---|
| 512 specialist features | 0.630952 |
| All 200 raw species logits | 0.607143 |
| 576 existing recipient features | 0.690476 |

Specialist features versus logits: two pair wins, two losses, ten ties; mean paired difference .023810. The six species supply 3/2/4/1/3/1 pairs, not independent broad replications. This descriptive contrast does not establish significant superiority or general equivalence. The recipient comparator has the highest aggregate score. Full logits retain image-dependent graded information; the hard species identity tie baseline (.5) cannot establish that logits are inadequate.

`cache_integrity_review` independently reproduced every saved prediction exactly from cached inputs/readers, verified raw-vote aggregation, all pair scores and training-only normalization/spectra. Thirty-six nonconstant readers attain 15 slope degrees of freedom; attributes 109/115/119 produce nine deliberate constants. This is independently checked ordinary supervised access under one reader family, not zero-shot questions, unseen attribute types or reasoning acquired without reader preparation. Equal degrees of freedom does not equalize inductive bias.

**Annotation qualification, without rescoring.** Root and independent reviewer `alignment_contribution_review` inspected images 6164/6160, 7027/7015 and

10047/10042 because confidence does not verify body-region visibility. The first pair includes a visible white front strip in an image labeled white-absent; the second does not plainly verify the claimed iridescence; the third changes which body regions are exposed. These selected diagnostics do not estimate annotation error prevalence or replace labels. Keep all locked pairs and original scores.
The outcome is agreement with retained annotations, not independently established visible breast-color discrimination. Do not interpret individual errors as proven perceptual failures.

**Cost and custody.** Test annotation extraction: 4,686,432 bytes / 2.000 seconds. Feature extraction: 180 CPU forward calls, 18.401 seconds internally and 19.627 supervised seconds; maximum logit discrepancy from S58 is zero. Fitting: 45 reader preparations, 4.464 seconds internally and 5.464 supervised seconds. Both attempts completed within their external 120-second deadlines; no GPU or new weights. Float32 payload per image is 2048 bytes for specialist features versus 800 for logits, excluding serialization overhead. This storage comparison alone is not an end-to-end cost claim. Runner: 222 apparatus lines; session totals 1573 apparatus / zero reusable artifact-bearing code lines, eight probe blocks / zero building rounds. S58/S62 add 540 single-image forward calls to fifteen earlier batched calls.

**Reviewed interface decision.** This panel does not justify requiring specialist internal features. Retain full logits and existing recipient features as serious comparators; no universal sufficiency or latent-information impossibility follows. The R^n readers are scaffolding for a useful-interface decision. No new native law, cumulative acquisition or reasoning-model advance is established. Close this panel without tuning, attribute search or error-selected expansion. The next acquisition must have an independently motivated useful contribution beyond existing recipient access and legitimate matched teaching.

**Periodic review completed around 17:32 UTC**, after consolidation at 526a5ab and a separate entropy check. Fresh `s62_periodic_frontier` endorsed this bounded step and warned against a sequence of readout benchmarks. It distinguished later than species pretraining from unseen question types, and made the recipient control binding for the acquisition decision. Audit entry e1164; independent tool-assisted review, not a real CLI audit. Continue the broader program.

### S63. A contribution to persistent object identity — source question

**Denizen definition before a reproduction.** A useful temporal operation must preserve which object is being followed and which extent of that object is meant, not merely classify each frame independently. Consider a service whose state contains an object reference and mask, and whose next-frame operation updates both. A contributed representation is useful if it improves that operation relative to the existing visual service and a competent direct tracking alternative. Any new memory, decoder training or object-association algorithm receives separate credit. This is an application of operational identity and continuation, not a claim that cosine neighbors define identity.

The so-what is: combine a model that finds object boundaries with a representation

that helps keep track of the same object over time. S61's primary source explicitly points to a downstream use of its combined backbone and segmentation adapter. Inspect that single source, *VideoSAM: Open-World Video Segmentation*, to identify the contributed operation, required new preparation and actual attribution controls. This is not S50/S51's closed endpoint hunt or another attribute-reader benchmark. No model download, local reproduction or architecture construction is selected.

**Primary evidence and independent review.** [VideoSAM v1](https://arxiv.org/html/2410.08781v1), sections III–IV, uses mutual cosine matches to propagate segmentation prompts, retains reference patches/masks in memory, and carries an autoregressive object prompt for granularity. The encoder stays frozen; the decoder receives LoRA training and new prompt components are trained on annotated videos. Table III compares representation choices with propagation and memory retained: the combined encoder improves UVO mAP and BURST recall, but not UVO recall or BURST mAP. Table V separately tests object prompts and cycle training. Figure 2 uses oracle masks for pooled-feature association; it cannot establish intrinsic information absence. Default UVO figures differ between Table I and Tables III/V, so their gains must not be combined as one setting. BURST retains objects present throughout; robot-video examples are qualitative. Original image-service retention and successive donor admission are not demonstrated.

**Operational consequence.** This is a useful precedent for contributed features participating in a repeated state update. The representation, association rule, memory and trained consumer all contribute; the behavior cannot be credited to the frozen encoder alone. Object identity and intended object extent are different state obligations: finding the right location does not settle whether the requested mask denotes a part or the whole object. Mutual nearest matches are a heuristic, not a guarantee of identity through occlusion or ambiguity. The native target is the externally usable identity/extent operation, not cosine geometry itself.

Independent `alignment_contribution_review` upholds this constructive interpretation and its mixed attribution evidence. A serious comparator retains segmentation and association encoders separately with the same competent temporal consumer; the source does not isolate the advantage of joint distillation over that alternative. Thus the concrete acquisition uncertainty is the value of the combined contributor inside a fixed useful temporal service, with later consumer learning charged. No checkpoint hunt or large reproduction follows. Close the bounded source read; do not reinterpret oracle-mask diagnostics as universal latent-space holes.

### S64. Recovery after ambiguity — select contribution before migration

**Definition and direction challenge.** For an established object reference and requested extent, recovery means resuming the correct reference after an ambiguous interval. A contributor's value is its incremental improvement in this operation over an equally prepared existing service, with memory, reference access and legitimate consumer learning available to both. Initial mask quality, association, memory selection and recovery are distinct possible sources of improvement. The so-what is: teach a system to find the same object again without silently switching to a similar object or changing which part was requested.

Root considered migrating temporal state across providers. Independent direction reviewer `s62_periodic_frontier` rejected selecting that work before binding a useful provider improvement: raw-reference reuse and reader repair already appear in S14 and S28–S34. Root accepts the correction. The next bounded source contrast checks an added representation (EntitySAM) against a direct memory/search remedy (SAM2Long), asking which operation each actually improves. No model reproduction, checkpoint hunt or new apparatus is selected. A contributor-specific recovery ablation would justify sharper acquisition design; improvement explained only by initial segmentation or memory policy would redirect the question accordingly. The simplest confound is attributing a better consumer's use of existing evidence to additional representational knowledge. Cosine alignment remains scaffolding; the target is preserved operational reference, not matching vector geometry.

**Bounded primary-source contrast.** [SAM2Long v3](https://arxiv.org/html/2410.16268v3), sections 3.2–3.3 and Table 6, changes memory/search without new weights. Three paths versus the reported one-path baseline improve SA-V/LVOS scores from 76.3/83.0 to 80.8/85.4, with throughput 22 to 19 FPS and memory 5.1 to 5.3 GB on an RTX 3090. This is a direct remedy, not free inference. Its final output selects the highest-scoring trajectory after the final frame. Its description therefore does not by itself establish the same gain for irrevocable online decisions. Multiple-hypothesis tracking is explicit prior art, not a newly discovered native law. Aggregate ablations do not prove every occlusion is solved.

Independent reviewer `alignment_contribution_review` read the [final EntitySAM paper](https://openaccess.thecvf.com/content/CVPR2025/papers/Ye_EntitySAM_Segment_Everything_in_Video_CVPR_2025_paper.pdf), sections 3.3–4.1 and Tables 2/5/8/9. Adding DINO features raises video entity quality 50.2 to 51.8, but that ablation lacks recovery-specific attribution or controlled initial masks. Enhanced features feed learned prompts on every frame; the gain cannot be assigned exclusively to initialization either. Preparation includes 40k image and 10k pseudo-video iterations; SAM2 encoder/memory are frozen while fusion/prompt/decoder components learn. The inspected prose leaves DINO backbone freezing ambiguous. Better initial prompts are a strong comparator; composite segmentation quality and tracking quality can move differently.

**Decision and transferable residue.** The sources concern different tasks and systems; their numbers are not a head-to-head comparison. An existing model can support a better temporal operation when its consumer retains alternatives instead of committing early. Added features can help a learned segmentation service, but this pair of sources does not isolate an added recovery ability. Keep evidence availability, proposal generation, selection, memory contamination and decision timing distinct when attributing a future contributor's effect. Missing attribution is not negative evidence about the donor. Do not turn the distinction into another generic proof or construct a tracking benchmark without a bounded acquisition hypothesis. Close this source selection; no model work or new runner lines.

**Second direction exchange.** `s62_periodic_frontier` agrees with closure but identifies selection avoidance: demanding a perfect donor-specific recovery case

would repeat the earlier mistake of disallowing useful modest precursors. Root accepts its S25 two-hop revision recommendation. Next bind one semantically valid relation family, compare direct authoritative record delivery with omission and report prerequisite competence beside composition and eligible coverage. A possible employer-to-headquarters relation is only an illustration until the actual rule is inspected. No error-driven case replacement, weight editing or second model is needed for the first consumer test. It does not yet demonstrate learned-donor acquisition. Board entries e1169/e1170 retain reviewer provenance.

### S65. A supplied revision used in a subsequent traversal — completed diagnostic

**Definition before compute.** Let a source record replace relation r(s)=o with r(s)=o', while a second relation q remains unchanged. The requested continuation is q(o'), stated explicitly enough that the composition is licensed. Compare answers when the authoritative replacement is supplied versus omitted; separately query the replacement and the prerequisite q(o'). This tests whether a prepared consumer can use a newly supplied distinction, not whether it learns composition from the record or acquires another model's computation. A record can be a useful interface without establishing a novel native law.

**Expected outcomes and confound.** Correct prerequisites plus improved composed answers would justify investigating a learned contributor or assimilation step. Failed prerequisites would instead locate a consumer/data limitation. Little change with strong omission performance would indicate limited room for this particular correction. The cheapest confound is a poorly specified counterfactual or a query that already names the answer-producing intermediate; audit the rule and wording before inference. Do not replace difficult cases after observing outputs. Report the whole fixed panel and eligible prerequisite coverage, not only a conditional success rate. A direct structured lookup is the exact baseline when both relations are supplied, and any later learned donor must justify itself against that option.

Bound selection to one official RippleEdits relation family and a small fixed panel. The existing cached 0.6B consumer is the candidate; no weight download, GPU, weight editing or large-model load. Generation uses its pinned chat template with thinking disabled as the direct budget remedy. A frozen manifest and external CPU deadline must precede execution; this section does not report a run.

**Frozen proximal allocation.** Official RippleEdits revision `54f3b88af4895a3aacb580ec63ce7ae857185040`, `data/benchmark/popular.json`, supplies citizenship-to-capital composition. Independent source inspection found subnational, historical and fictional replacements in the early records. Before any inference, the illustrative country whitelist was replaced by the explicit semantic rule current sovereign-country replacement with one recorded capital. The bounded 4,194,304-byte prefix has 321 complete records and yields the three selected indices 0/49/177: the stipulated new citizenships are Syria, Malawi and South Korea. These are hypothetical replacements, not claims about these people's citizenship. The original six-case proposal is reduced to a three-case proximal test because of valid source support; no model scores selected the cases. Root independently

re-fetched the same prefix and retained full selected source records; prefix hash `5b8c49c64f74f63afd8b4f81ebf47b0c511f2c83f8e250704ac47814e7988f15`. The reviewer also fetched a 4MiB prefix without retaining its hash; that traffic is additional preparation, not model compute.

Design review `cache_integrity_review` adds the strongest cheap confound control: give the same new country to another panel subject, then ask the original person's composed question. This tests intermediate-name priming without proper binding. Six arms per case: original first hop, new-country capital, supplied first hop, composed omission, composed valid record and composed wrong-subject record. No-record agreement with a counterfactual answer is headroom, not ordinary factual accuracy. Wrong-subject agreement is new-answer intrusion; old-capital correctness is not bound by the source packet. Do not silently score it as full accuracy.

The frozen design is `experiments/results/relation_revision_v1/design.json`, SHA256 `7ccc937585afa1756fc7ee47a3e5b282eb0e38a9eedee4ae49e2b02644fcfb6a`. Cached Qwen3-0.6B revision `c1899de289a04d12100db370d81485cdf75e47ca`, float32, two CPU threads, pinned tokenizer/template/weights, greedy generation, thinking disabled, at most 16 new tokens per response. Eighteen requests, 120-second external deadline including imports/loading and 6GiB process memory ceiling. Every completed response is checkpointed. A timeout is execution-inconclusive, not a reasoning negative. Require all baseline responses to terminate for any capability wording; show all outputs and prerequisite-eligible coverage. The 127-line runner is apparatus, not a reusable acquisition artifact. No weight editing or donor yet.

Final actual-prompt and runner review by `cache_integrity_review` gives design GO. A short explicit ready-state wait resolves its identified supervisor startup race. Allocation is in the ledger before launch; supervisor PID11140, child PID28012. Only the completed receipt and response packet determine the outcome.

**First execution failed at custody, not reasoning.** After one generation returned, the result writer rejected a set in the library's loading metadata. The saved `result.json` still says loading/zero forwards; that is a stale pre-load checkpoint, not evidence of zero computation. One response returned, none persisted; actual forward count is unrecorded, bounded 1–16 by the code. Supervisor receipt records 81.6978 seconds and peak RSS 5,249,433,600 bytes, exit 1. Preserve both receipt and logs. No accuracy or termination observation is recoverable from that attempt.

`cache_integrity_review` endorses one deliberate bounded retry after a narrow fix: normalize loading metadata and successfully checkpoint it before generation. A no-model serialization fixture passes. The same design hash, 18 prompts, 120-second deadline and memory ceiling remain; separate retry receipt/results/logs preserve the failure. Final runner is 137 apparatus lines. A second execution failure ends this allocation without another repair loop. Partial response coverage, if any, must remain explicit and cannot support a whole-panel claim.

**Completed retry and manual result review.** The retry completed in 51.4761 supervised seconds with 111 recorded forward calls and all 18 outputs persisted. Every arm terminates 3/3 (18/18 total). Root and `alignment_contribution_review` manually read all outputs; `cache_integrity_review` independently checked design

hash, request order, token limits, EOS and the complete decoded responses.

| Question/condition | Correct or target agreement | Termination |
|---|---|---|
| Original citizenship | 2/3 correct | 3/3 |
| Supplied citizenship | 3/3 correct | 3/3 |
| New-country capital prerequisite | 0/3 correct | 3/3 |
| Supplied composed capital | 0/3 correct | 3/3 |
| Composed omission | 0/3 agreement with counterfactual capital | 3/3 |
| Composed wrong subject | 0/3 target-capital intrusion | 3/3 |

All capital prerequisites and valid composed answers name countries. The wrong-subject arm additionally misattributes South Korea citizenship to Shaleen Bhanot when the record concerns Leonardo DiCaprio. Zero capital intrusion does not mean correct binding: it would miss this country-level misattribution. Full outputs and manual qualifications live in `relation_revision_v1/result_retry.json` and `review.json`. There are **zero prerequisite-eligible cases**. No conditional composition accuracy can be estimated. Successful first-hop copying establishes neither selective revision nor donor-computation acquisition.

The licensed conclusion concerns this exact sentence-completion interface; it does not establish absent capital knowledge, inability to compose competent prerequisites, or an intrinsic latent-space hole. Ordinary relation traversal is the operational target, not a newly demonstrated native law. No new teacher or weight update occurred. Total attempt wall time is 133.174 seconds; total new forwards are bounded 112–127, not 111 alone. Session apparatus is 1710 lines, nine probe blocks, zero building rounds. First and retry receipts stay separate; stale first-result counters are not actual execution totals.

**Paused closeout, user-directed.** Both reviewers support one next diagnostic: only the same three capital prerequisites as natural direct questions under a neutral QA instruction, with no supplied capital answers or demonstrations. Freeze that bundled wrapper remedy before inference; success would justify separately selecting a natural-question composition contrast, while repeated prerequisite failure would motivate a pivot without prompt search. The user requested closure before this diagnostic; it is UNRUN and NOT QUEUED. No third execution of the cloze allocation, new model or automatic continuation is authorized during this pause. Read docs/HANDOFFS.md on return. The mission remains open.

# HP: Spectral Law of Zipf-Trained Superposition Codes (v2)

Status: PRE-REGISTERED v2, frozen before any HP-A/HP-B run. v1 was gated NO-GO by an independent Droid design review (ledger `hp1_design_gate_droid`); v2 incorporates its five required fixes and its strategic steer (analytic foundation cycle first). v1 is preserved in git history.
Date: 2026-09-18. Program: mathematics of high-dimensional spaces (ACTIVE).

## 0. Structure

 **HP-A (this cycle): analytic + Monte-Carlo foundation.** No SGD. Exact mean-field stationarity of the superposition objective; the finite-d random-frame spectral map; estimator validity (when is a fitted power-law exponent a measurement rather than an artifact); exact early gradient-flow law with an independent pilot calibration.

 **HP-B (next, after HP-A): optimizer cycle.** Tests transient-vs-equilibrium on trained codes with the repaired design.

## 1. Question (unchanged in substance)

Is the power-law exponent of a superposition code an equilibrium quantity of the training objective or a transient frozen by finite optimization time? Entry 101's "steady state" claim is unsupported (its loss is still decreasing at t=3000); toy exponents (≈1.0–2.4) sit far above the rate-distortion benchmark s/2 and above real-model exponents (≈0.35–0.57).

## 2. Definitions

 $p_i = i^{-s}/H_{n,s}$; $W \in R^{d\times n}$; $\gamma = n/d$; $x_i = \|w_i\|^2$; frame spectrum = eigenvalues of $WW^T$ sorted desc; $\lambda_k \sim k^{-\alpha}$ by convention.

 QSAE: $L(W) = \Sigma_i p_i (x_i-1)^2 + \Sigma_{i\neq j} p_i x_i x_j (u_i\cdot u_j)^2$.

 Estimator battery (frozen, used everywhere): windows {top-50%, top-90%, full-d} of ranked eigenvalues; within each window two fits — power law ($\log \lambda = a - b \log k$) and curved alternative ($\log \lambda = a + b \log k + c \log^2 k$); $\Delta R^2 = R^2_{pl} - R^2_{quad}$. Primary window: top-90%.

## 3. Corrected propositions

**P1′ (exact mean-field stationarity).** Under random mixing ($E(u_i\cdot u_j)^2 = 1/d$, $i\neq j$, independent of norms), $\Phi(x) = \Sigma_i p_i(x_i-1)^2 + d^{-1}[M X - \Sigma_i p_i x_i^2]$ with $X = \Sigma x_i$, $M = \Sigma p_i x_i$. Stationarity gives EXACTLY

$x_k = (d/(d-1)) \cdot [1 - (X + M/p_k)/(2d)]$, clipped at 0,

with (X, M) determined self-consistently (two-scalar fixed point). The optimal

norm profile is a bulge with a usage cutoff $k_0 = (2d\, c_0/(c_1 H))^{1/s}$-shaped boundary — NOT a power law. No flatness claim for the induced frame spectrum is made here; that map is finite-d and measured in A2. Rate-distortion s/2 is retired as a direct comparator (n tokens vs d modes; no token-to-mode assignment is defined) and kept only as a labeled diagnostic.

**P3′ (exact early flow).** The exact QSAE gradient at small ‖W‖ is dominated by the −4·W $D_p$ term, so $dx_i/dt = 8\, p_i\, x_i$ (continuous time t = lr·steps): growth is EXPONENTIAL at usage-proportional rates, saturating logistically toward $x_i^*$: $x_i(t) \approx x_i^*/(1 + (x_i^*/x_i(0) - 1)e^{-8\, p_i\, t})$. Saturation clock $t_i \approx \ln(x_i^*/x_i(0))/(8p_i)$. HD sharpening: for Gaussian init, $x_i(0)$ concentrates (relative fluctuations $O(\sqrt{(2/d)})$), so $\ln x_i(0)$ spreads only $O(1/\sqrt{d})$ — concentration of measure makes the formation transient SHARP. $k_{sat}(t) \approx t^{1/s}$ up to those log-corrections. No monotone-α claim: whether $\alpha_{fit}(t)$ is monotone is an outcome, not a prediction.

## 4. HP-A pre-registration (frozen)

**A1 (mean-field endpoint adequacy).** Solve the P1′ fixed point for $(s \in \{0.5, 1.0\}) \times (n,d) \in \{(64,16),(256,64),(512,128)\}$. Compare to L-BFGS optima of the true QSAE (5 independent inits each, converged: gtol 1e-10). Verdict on norm-profile shape $R^2$ (fit of $x_{(k)}$ to the P1′ form on the unclipped region, median over inits): > 0.9 mean-field adequate; 0.8–0.9 partial; < 0.8 refuted (optimal directional correlations beyond mean field — promote to HP-C target).

**A2 (random-frame spectral map + estimator validity).** Monte Carlo (20 draws): norm profiles from (a) A1 bulge solutions, (b) power-law $x_{(k)} \propto k^{-\beta}$, $\beta \in \{0.25, 0.5, 1.0\}$, (c) uniform; $d \in \{32,\ldots,1024\}$ ×6, $\gamma \in \{4, 16\}$. Pre-registered verdicts:

- A2-i: PL input, $d \geq 256$: $|\hat{\alpha} - \beta| \leq 0.10$ in top-90% window (medians).
- A2-ii: bulge input with $k_0 < d/2$: power-law $R^2 > 0.95$ in ≥ 1 of 3 windows at $d \leq 64$ (manufactured power laws quantified) AND $\Delta R^2$ flags curvature ($R^2_{quad} - R^2_{pl} \geq 0.02$ in the same window).
- A2-iii: uniform input: $\hat{\alpha} \leq 0.35$ at all $d \geq 64$ in all windows.
- A2-iv (new, window-stability rule): any later trained-code α claim requires $|\hat{\alpha}(\text{top50}) - \hat{\alpha}(\text{top90})| \leq 0.15$ and $\Delta R^2 \geq -0.02$ (curved not better).

**A3 (transient law + independent pilot).** Build $\alpha_{pred}(t)$ by mapping the P3′ logistic norm trajectories ($x^*$ from A1, x(0) from Gaussian init) through the A2 spectral map at (d=64, γ=16, s=1). The single free rate constant is calibrated ONLY on an independent pilot: direct Euler integration of the exact QSAE gradient flow at (64,16,s=1), seeds 90–92, matching α at the pilot's FIRST checkpoint only. Grid runs never touch the calibration.

**N1-t (adopted control, standing).** At any checkpoint of any trained code: preserve learned column norms, redraw directions independently; compare α trajectories. Separates norm-driven from direction-driven spectral evolution.

## 4b. A1 result and theorem (recorded 2026-09-18, before any HP-B run)

**A1 verdict: mean-field ansatz REFUTED at every configuration** (profile-fit $R^2$ 0.00–0.08 vs thresholds 0.9/0.8; identity $R^2$ 0.10–0.53). The reason is a theorem the L-BFGS optima exposed (loss matched $\Sigma_{i>d}\, p_i$ to 6 decimals at all six (s,n,d)):

**Theorem (sparse-exact optimum of the QSAE).** Let $G = W^T W$ (rank $\le d$). $L = \mathrm{tr}((G-I)\, P\, (G-I))$ with $P = \mathrm{diag}(p)$. G is PSD with rank $\le d$, so $G-I$ has an $(n-d)$-dimensional kernel-inherited subspace on which it acts as $-I$ (eigenvalues of G on ker G are 0). Hence $L \ge \mathrm{tr}(P|_{\ker G})$, minimized by choosing $\ker G = \mathrm{span}\{e_i : i \in S\}$ with S the top-d usage set, giving $L_{min} = \Sigma_{i \in S}\, p_i$, attained by ANY orthonormal unit-norm set $\{w_i\}_{i \in S}$ (G = coordinate projector onto S). The optimal frame operator is $W W^T = I_d$: **completely flat spectrum, condition number 1.**

Consequences (now part of the cycle's frozen expectations):

- **P-E (added before any HP-B run):** converged QSAE GD endpoints show $\hat{\alpha}(\text{top90}) \le 0.35$, $\approx d$ nonzero norms, and loss within 1e-6 of the tail mass.
- Power-law spectra CANNOT come from the quadratic objective's optimum. They must arise from (i) optimization dynamics (transients) or (ii) non-quadratic retrieval geometry (softmax margins). The XE arm is therefore the main event of HP-B; the QSAE arms test the dynamics-only branch.
- HD-native moral: the quadratic reconstruction loss has no superposition premium — with $d \gg n$, interference is avoided by DROPPING tokens. The cost of superposition only bites when every token must remain retrievable (softmax), which is the real-embedding regime. The rate-distortion s/2 benchmark and the mean-field bulge both describe the wrong object for this loss and are retired as comparators for QSAE.

## 5. HP-B design (repaired; frozen after HP-A lands)

- Grid: $s \in \{0.5, 1.0\}$; $(n,d) \in \{(256,64),(1024,64),(1024,256)\}$ plus (4096,64) s=1 only ($\gamma$=64); 3 seeds (0–2). No $\alpha(s,\gamma)$-surface claim from this grid — mechanism claims only.
- lr frozen by independent loss-based pilot (seeds 90–92; choose lowest final loss among stable {0.002,0.01,0.05,0.2} at (1024,64,s=1), 2k steps).
- QSAE GD checkpoints {1e3,1e4,5e4,1e5,2e5}. Convergence gate (all three): $|\alpha(\text{last two checkpoints})| \le 0.05$ (top-90 window), loss slope < 1e-5/1k steps, grad-norm < 1e-3 × init grad-norm. Frozen extension schedule: ×4 steps, up to 3 extensions, else verdict UNCONVERGED (no endpoint claim).
- P-A′ (endpoint profile): fit P1′ form on $x_k > 1e\text{-}8 \cdot \max x$; verdict on median-of-seeds $R^2$ with the A1 thresholds.
- P-B′ (mean-field spectral adequacy): endpoint spectrum vs median of 5 N1-t-style random-direction replicates with the fitted endpoint norms; $\Delta R^2$_identity form (log-actual on log-model); scoring rule frozen: adequate if $R^2_pl(\text{actual}) - R^2_\text{identity} \le 0.05$.
- P-C′ (transient): score $\alpha_\text{pred}(t)$ vs measured at the 4 NON-calibration checkpoints; pass = $|\text{dev}| \le 0.10$ at $\ge 3$ of 4.
- P-D′ (XE replication, entry-101 config n=1024,d=64,s=1, tied softmax,

Adam 3e-3, batch 256): checkpoints {3k,12k,48k,192k}; equilibrium gate = A2-iv window stability + the convergence gate (loss slope, grad norm); frozen extension ×4 up to 3×. Interpretations pre-registered both ways.

□ Nulls: N2 uniform usage (flat, $\hat{\alpha} \leq 0.35$); N1 endpoint randomization; N0 L-BFGS multi-init vs GD endpoint (max per-eigenvalue rel dev < 5% □ objective-determined).

## 7. HP-C propositions (drafted 2026-09-18, before any HP-C run and before the HP-B XE job reported; its endpoint signatures below are therefore pre-registered predictions for the running experiment)

**H1 (unigram softmax collapse).** For tied-embedding full-softmax CE on independent Zipf-distributed tokens, with $d \geq 2$ there exist exact optima of the form $w_i = u + \alpha_i e$ with $u \cdot e = 1$, $\alpha_i$ □ $\log p_i$, in the $\|u\| \to \infty$ limit: logits $z_{ij} = K + \log p_j + o(1)$, i.e. the target distribution is realized exactly. Consequences for the endpoint:
(i) token norms UNIFORMIZE ($\|w_i\| \to \|u\|$; the log-frequency spread is lower-order); (ii) the Gram/frame spectrum is TWO spikes (common direction u; frequency direction e) + floor — essentially rank 2, NOT a power law; (iii) therefore any power-law spectrum measured at finite training time on unigram data is a TRANSIENT (norm bulge read through the A2-biased estimator), not equilibrium structure; (iv) N1-t diverges from the measured spectrum because the learned coherence (common u) is directional structure that norm-preserving randomization destroys.
XE endpoint signatures (frozen): norm spread ($\max\|w_i\|/\min\|w_i\|$ over top-d usage tokens) collapses toward O(1); top-2 eigenvalue share rises; fitted α drifts as the 2-spike shape replaces the transient profile. If instead a power law persists at convergence, H1 is refuted and the softmax equilibrium requires the margin-based theory the prior-art agent is currently scoping.

**H2 (structured-data inheritance — HP-C core for real embeddings).** With co-occurrence structure, converged softmax training approximates a rank-d factorization of the log-conditional matrix $M_{ij} = \log P(j|i)$ (matrix-factorization view of SGNS; caveats: softmax ≠ LS, negatives sampling, regularization). Then the embedding spectrum INHERITS the top-d spectrum of M: the source of real-model power laws would be the DATA's correlation spectrum, with Zipf marginals entering through norms and the frequency direction but not directly through the spectral exponent. Distinguishing prediction from any usage-driven allocation theory: the embedding exponent should track the M-spectrum exponent across corpora at fixed (n, d), and be insensitive to marginal reweighting that preserves correlations. HP-C test (later, pre-registered separately): matched-corpus M-spectra vs trained embedding spectra.

## 8. HP-C1 pre-registration draft (H2 test: spectral inheritance from data)

Status: DRAFT — frozen before any corpus M-spectrum is computed; final freeze

waits only on the running prior-art report (to cite/avoid duplication), not on any data.

**Question.** Do real-model embedding power-law exponents match the top-d spectrum of the log-conditional (co-occurrence) matrix of matched training-like data? (H2: inheritance from data structure; the toy results show both quadratic and unigram-softmax equilibria lack genuine power laws.)

**Frozen choices.** Corpus: WikiText-103 train (~100M tokens; fallback: a The-Pile sample if download fails; fallback 2: local corpus with the mismatch logged). Per model (SmolLM2-135M, Qwen3-0.6B, Phi-1.5 — the three with existing embedding-spectrum records): tokenize with the model's own tokenizer; count symmetric-window (±2) co-occurrence $C_{ij}$; $M_{ij} = \log((C_{ij} + \alpha)/(r_i + \alpha \cdot n))$ with $\alpha = 0.1$ (smoothing sensitivity checked at $\alpha \in \{0.01, 1\}$); top-d singular values via randomized SVD (rank d = model width); exponent via the SAME battery (top-90% window, curved alternative, $\Delta R^2$).

**Frozen verdicts.** Primary: $|\alpha_M - \alpha_{emb}| \leq 0.15$ per model (same estimator on both objects) → inheritance supported (scope: this corpus-model pairing). All three $|dev| > 0.30$ with embedding exponents systematically shallower → inheritance refuted at this pairing; optimization-bottleneck and margin-allocation stories survive. Mixed → inconclusive; report shape distances (log-space W1 over top-d) diagnostic only. Embedding spectra re-measured with the battery from cached weights; prior single-number readings retained as context.

**Declared confounds (unavoidable, logged):** corpus ≠ actual training mix; tokenizer-vocab truncation; smoothing and window choices; d-window matching.
**Vocabulary cap (declared before any M-spectrum is computed):** co-occurrence vocabulary restricted to each tokenizer's K = 8192 most frequent tokens (covering the bulk of mass; tail mass logged) — full $152K^2$ counting exceeds laptop memory. The comparison object is the top-d ($d \leq 2048$) spectrum, which frequent-token structure dominates; the cap is part of the frozen design.

**Cost:** CPU only; tokenization minutes, sparse counting minutes, randomized SVD minutes per model. One canonical runner `experiments/run_hpc1_inheritance.py`.

## 6. What each outcome licenses

- A1 refutes mean field at the optimum: directional correlation is created by the OBJECTIVE itself (not just dynamics) — HP-C targets its structure.
- A2-ii confirms manufactured power laws: a measurement-validity constraint retroactively qualifies every prior $d \leq 64$ spectral reading in the record.
- HP-B transient wins: the law is $\alpha(t)$; toy-vs-real exponent gap is a training-time artifact. HP-B equilibrium wins: HP-C derives the softmax equilibrium surface $\alpha_{eq}(s,\gamma)$ on a widened grid.

--- SOURCE FILE: theory/HPD_ALLOCATION_THEOREM.md ---

# HP-D: The Usage-Weighted Margin-Allocation Theorem

Status: OPENED 2026-09-19 (post review-2 pivot; the verified unoccupied gap).
Math-first: this document states the full specification, the target theorems,
and the first reduction BEFORE any HP-D computation. Prior-art scoping
(ledger `priorart_allocation_gap`): no published derivation of eigenvalue
allocation for CE/softmax-trained representations from usage in the
overcomplete regime; balanced neural collapse predicts FLAT spectra;
reverse water-filling is MSE-only.

## 0. Specification (the discipline the adversarial review demanded)

 **Ensemble.** Vocabulary [n]; usage p_i = i^{-s}/H_{n,s} (monotone; Zipf family). Code W  R^{d×n}, columns w_i = √x_i v_i, ‖v_i‖ = 1; γ = n/d ≥ 1.

 **Task.** Tied retrieval: context I ~ p, query direction q = v_I; target J | I ~ (1−ρ)·unigram(p) + ρ·structured(P(·|I)). ρ = 0 case is solved (H1: rank-2 collapse). The theorem concerns the joint-retrievability constraint structure the ρ > 0 part imposes.

 **Decoder.** argmax_j z_j, z_j = w_j·q (logit-margin m bounds softmax CE error by e^{−m} up to constants; both stated where used).

 **Noise/interference model.** For target j, interference logit I_j = Σ_{k≠j} √x_k (v_k·q)(v_j·v_k·correction) — subgaussian with variance proxy σ_j² = Σ_{k≠j} x_k (v_j·v_k)² c(q-geometry). Tail control beyond Gaussian via degree-2 concentration (Hoeffding/chaos; T3 below).

 **Error criterion.** Per-token misretrieval ε_j = P(argmax ≠ j | target j). Objective: minimize Σ_j p_j ε_j subject to spectral budget Σ_j x_j = P.

 **Capacity claim protocol.** Any k(d) threshold statement must fix all of the above before it is a theorem (reviewer's rule, binding).

## 1. Target theorems

**T1 (reliability floor).** ε_j ≤ exp(−t_j²/2) with t_j = (√x_j a_j − m_j)/σ_j (a_j = query-target alignment) — Gaussian-proxy form; T3 replaces it with a chaos tail carrying explicit d-dependence.

**T2 (allocation — the main target).** The budget-optimal profile x* solving the KKT system; characterize x*_(k)'s shape and the induced frame-spectrum allocation. Two pre-registered outcomes:

 **T2-LOG:** under uniform coherence (μ), optimal allocation is x_(k)  (m + c√log(1/p_k))² — logarithmic-squared, NOT a power law; the induced spectrum is curved-shallow; any measured power law then requires structured coherence (organization), data-correlation spectra, or dynamics.

 **T2-PL:** coherence structure μ(j,k) co-optimizing with usage admits a power-law allocation with exponent α(s, γ) — derive α or refute.

**T3 (hierarchy rigor).** For isotropic subgaussian directions, the t-body interference terms concentrate with d^{-(t-1)/2} suppression (Hoeffding/Wiener-chaos), yielding the tail constants in T1/T2 with explicit d, γ.

## 2. First reduction: uniform coherence (T2-LOG derivation sketch)

Set (v_j·v_k)² = μ for j ≠ k; σ_j² = μ(X − x_j), X = Σx. Misretrieval

ε_j ≈ Φ̄(t_j), t_j = (√x_j − m_j)/√(μ(X − x_j)). Lagrangian optimality on Σx = P with objective Σp_j ε_j: the marginal condition equalizes p_j·|∂ε_j/∂x_j| (reliability-allocation classic). With Φ̄(t) ≈ φ(t)/t: ∂ε_j/∂x_j ≈ ε_j·t_j/(2√x_j σ_j); the optimum satisfies p_j ε_j t_j/(√x_j σ_j) = c ⇒ t_j² ≈ 2 log p_j + O(1) ⇒ √x_j ≈ m_j + t_j·√(μX) ⇒ **x_j ≈ (m + √(2μX·log(1/p_j)))²** — grows only as log²(1/p_j) in usage rank. Consequences (to be stated as lemmas with proofs): (i) induced norm profile is curved-log, its battery signature is "curved-beats-power-law" — matching the XE interim (ΔR² < 0 everywhere); (ii) NO exponent α(s, γ) exists in this specification; power-law spectra are not explained by usage + uniform superposition; (iii) the folk claim "superposition over Zipf features ⇒ power-law spectra" is false in this (fully specified) model. What remains as power-law sources: structured coherence co-optimized with usage (T2-PL), data-correlation spectrum inheritance (H2 with gauge fixed — whitened/balanced observable, full-shape comparison only), or optimization dynamics.

## 2b. Derivation progress notes (2026-09-19, pre-proof capture)

Two independent channels both yield LOG-type allocation; both must be formalized as lemmas before T2-LOG is claimed:

**L1 (subgaussian-max channel).** Under uniform coherence, the binding interference for retrieving pair (I, j) is the MAXIMUM competitor logit, whose scale is √(μ X_max · 2 log n_eff) (n_eff = effective count of near-max-norm competitors). Required: √x_j c_Ij ≥ √(μ X_max 2 log n_eff). Consequences: (i) the margin constraint is (to leading order) norm-SCALE free — it constrains geometry (c, μ) not budget; (ii) feasibility reads 2μ log n_eff ≤ c²_min — a coherence-capacity condition recovering the interference-hierarchy bound in disguise (T3's job: make this exact with chaos tails); (iii) where norms DO bind (alignment heterogeneity c_Ij), x_j ≈ log(n_eff)/c²_Ij — logarithmic.

**L2 (CE logit-margin channel).** Softmax excess loss for pair (I, j) forces z_j − z_k ≈ log(p_k/p_j)-type separations against every sizeable competitor (continuous version of the union bound; exact statement via the classical multinomial logistic margin bound). Under uniform coherence the separation requirement enters norms as x_j ≈ (log usage-ratios)²/c² — again logarithmic-squared in usage rank, consistent with the reliability-KKT sketch in §2.

**Caveat to resolve (flagged, not hidden):** in the pure union-bound regime the problem is nearly norm-indifferent (L1-i) — allocation is determined by alignment heterogeneity and CE curvature, not raw norms. T2's formalization must therefore fix WHICH loss variant defines the budget-constrained problem (CE excess with explicit budget Σx = P and alignment profile c) before the allocation law is stated. Suspicion to test: power-law allocation can only enter through structured/heavy-tailed coherence (correlated interference) —

if L1+L2 are proved as stated, T2-LOG follows for ALL uniform-coherence variants, and the folk "Zipf superposition □ power law" claim is false across the entire uniform family.

## 2c. CORRECTION AND REDONE DERIVATION (2026-09-19; review-3 caught a sign error in §2 — this section supersedes §2's monotonicity claim)

The §2 marginal condition p_j ε_j t_j/(√x_j σ_j) = c with ε_j ≈ φ(t_j)/t_j gives, taking logs: t_j² = 2 log p_j + C(x, σ) — reliability margin grows with USAGE, not rarity (§2's "x_j □ (m + √(2μX·log(1/p_j)))²" had the monotonicity REVERSED; withdrawn). Consequences of the corrected condition:

- □ Frequent tokens: t_j² → C — bounded margins; x_j ≈ (m + √C σ)².
- □ Rare tokens: 2 log p_j + C < 0 — the tail linearization fails; the true optimum floors them at minimal functional norms (sacrificed in the usage-weighted sense; cf. minority collapse and the quadratic theorem's tail-dropping).
- □ Net: the optimal norm profile is FLAT UP TO LOG CORRECTIONS in this specification — no power law in either monotonicity. This coheres with all three toy results (sparse-exact optimum; XE normspread → 1.4; entry-95 random-norm flatness). **T2-LOG is restated as T2-FLAT:** under uniform coherence and the reliability-KKT specification, budget-optimal allocation is flat-with-log-corrections; no power-law allocation is optimal.

## 2d. Repairs required before T2-FLAT is claimed (per review-3)

1. Complete the specification: one CONCRETE structured transition kernel — block model: vocabulary in B usage-ordered blocks; P(J|I) = within-block association ρ + unigram remainder; alignment a_Ij derived from it.
2. Derive the interference law FROM the decoder: misretrieval of (I, j) is the event □k□S_I: √x_k (v_k·v_I) ≥ √x_j (v_j·v_I) − m; the competitor logit vector's joint subgaussian law (covariance from the coherence profile) replaces the hand-written sum in §0.
3. Prove allocation monotonicity (x* nondecreasing in p under the kernel).
4. **T4 (phase transition — the dimension-dependent invariant target):** for the block kernel, characterize the critical d*(n, ρ, s) below which usage-weighted retrieval error stays bounded — candidate scalings Θ(log n) (packing-like) vs Θ(√n) (coherent-like); a sharp threshold with explicit constants is the theorem this program wants.

## 5. The structured kernel and the T4 derivation (2026-09-19; repairs §2d)

**5.1 Kernel (concrete, planted block).** Usage p_i = i^{-s}/H_{n,s}; vocabulary split by rank into B equal blocks of size m = n/B. Transition: P(j | i) = (1−ρ)·p_j + ρ·(1/m)·1[block(j) = block(i)]. ρ = structure strength; ρ = 0 is the solved unigram case (H1). Target logits: z*_j(i) = log P(j|i) + c_i.

**5.2 Decoder-derived logits (repair of §0's hand-written noise).** Tied retrieval, z_j(i) = w_j·w_i exactly. Misretrieval of (i, j) is the event

□k: z_k(i) ≥ z_j(i) − 0 (argmax) or, margin version, z_k(i) ≥ z_j(i) − m_ε. ALL interference is competitor logits z_k(i) = w_k·w_i — no external noise variable exists or is needed. Every statement below is about the joint law of {w_k·w_i}_{k} under the code ensemble.

**5.3 Equilibrium ansatz (lemma to prove: optimality of decomposition).** w_j = a_j·f + b_j·u_{b(j)}, with f □ span{u_b}: the frequency direction f carries the unigram part (a_j □ log-scale of p_j, per H1's mechanism) and the B signature vectors u_b (unit norm) carry block membership. The task is exactly representable iff d ≥ B+1; **the superposition regime is d < B.**

**5.4 Interference law (lemma).** For i in block b, out-of-block competitor k in block b': z_k(i) = a_i a_k + b_i b_k (u_{b'}·u_b). Same-block target advantage: Δ_ij = b_i b_j (1 − u_{b(j)}·u_{b(i)}) + (a-terms, favorable since same-block targets need not beat the unigram part). With signature coherence μ = max_{b≠b'} u_{b'}·u_b: b_i b_k μ is the worst structured interference; the a-part is favorable (out-of-block frequent tokens have lower required log-prob, rare ones lower a_k).

**5.5 Threshold route (T4a statement).** Usage-weighted error ≤ ε requires, for typical (i,j same-block): b_i b_j(1 − μ) ≥ max_k [a_i a_k + b_i b_k μ] + σ·√(2 log(n/ε))-type subgaussian slack (exact constant from the chaos analysis, T3). Two regimes fall out:

□ **Welch regime:** B signatures in d dims force μ ≥ √((B−d)/(d(B−1))) (Welch bound; achievability caveats logged). Substituting gives the feasibility inequality in (d, B, ρ, s, ε, budget P) — solve for d*(B, ρ, s, ε, P). Conjectured form: d* linear-ish in B with a structure-strength factor — a genuinely dimension-dependent threshold.

□ **Packing regime:** B > d(d+1)/2 — equiangular signatures unachievable; μ jumps; the transition sharpens (candidate: d* ≥ c·B^{1/2} vs linear — the phase boundary this theorem hunts).

Budget coupling: Σ_j b_j² enters through the slack term — the allocation problem REDUX, now structured (b_j vs signature geometry jointly optimal), which is where any non-flat allocation law must live if it exists at all.

**5.6 Proof obligations (open, ordered):** (i) prove 5.3's decomposition is near-optimal for the CE objective (variational argument or counterexample); (ii) prove 5.4's favorable-a-part claim exactly (it interacts with s); (iii) chaos/Hoeffding tail for the max over n competitors (T3 machinery, fixing normalization per review-3's point 2); (iv) solve the feasibility inequality in both regimes; (v) pre-register the simulation that tests the threshold before running it (planted-block retrieval at (n, B, d, ρ, s) grid around the predicted boundary).

## 3. Planned falsification arm (design AFTER derivation, before running)

A margin-task simulation: hard-margin retrieval loss on Zipf tokens with explicit coherence control (random vs organized directions), budget-matched; pre-registered checks: (a) uniform-coherence arm reproduces T2-LOG shape

(log² profile; curved battery signature); (b) an organization arm (coherence concentrated among high-usage tokens) is required for power-law-like profiles. Numeric tolerances frozen at that point.

## 4. Provenance and status

Opened after review-2 (ledger `droid_review_2hr_1`) steering: capacity/ allocation theorems and interference rigor over slope matching. HP-C1 exponent-matching measurement stays PAUSED (gauge flaw; corpus asset kept). HP-B grids continue in background (dynamics branch evidence). Nothing in this document is claimed as proved until each lemma carries its proof and an evidence-gate pass.

## 6. PAUSED for repair (2026-09-19, review-5)

Two defects must be repaired before T4 proceeds (no HP-D simulations):
1. **Observation model:** the kernel samples J|I but the decoder receives only q = v_I; sampled-target argmax error includes irreducible Bayes uncertainty (the conditional entropy of J|I), which is not interference. Repair: full-distribution CE objective — minimize CE(P(.|i) || softmax(z(i))) — matching real training; error metric = CE excess over H(J|I).
2. **Representability:** tied logits W^T W are symmetric PSD; the target log-kernel is symmetrizable only in special cases, so "exactly representable iff d >= B+1" is WITHDRAWN pending proof. Repair: untied code (query matrix H, key matrix W; Z = W^T H general rank-d), with the tied/PSD variant stated as a separate constrained corollary; the gauge freedom noted by review-2 is then fixed by the CE optimum + regularization (the balancing principle), not assumed.
While paused, HP-E (theory/HPE_AGGREGATE_INTERFERENCE.md) carries the lead.

## 7. REPAIRED FORMALIZATION (2026-09-19; implements the review-5 repairs)

**Objective (full-distribution CE, matches real training).** Minimize over untied (H, W) in R^{d x n} x R^{d x n}:
L = -sum_i p_i sum_j P(j|i) log softmax_j(w_j . h_i).
Error metric: excess = L - H(P(.|I)) (conditional entropy floor). No sampled target, no argmax, no external noise; all interference lives in the softmax competition, decoder-derived by construction.

**Representability lemma (statement).** Zero-excess solutions exist iff some row-constant shift of the log-kernel, log P - 1 c^T, has rank <= d (Z = W^T H ranges over all rank-<=d matrices; softmax rows are shift-invariant).
Approximate form: excess CE <= g(tail energy of the centered log-kernel beyond rank d), with g quadratic-ish via Pinsker-type bounds (to be pinned).

**Planted-block log-kernel is approximately rank-(B+2).** log[(1-rho)p_j + rho/m 1_same] = logsumexp(log(1-rho)+log p_j, log rho - log m + M_ij) where M = block indicator. When one argument dominates, the logsumexp correction is additive-bounded; so log P = A_j + B-coeff*M_ij + E with ||E|| bounded by the

mixture-transition sharpness; A (unigram) contributes rank 1-2, M (block-diagonal ones) contributes rank B. The representability defect at d < B is governed by the weighted low-rank compression of M.

**Block-mass dichotomy (T4 in objective terms).** M has B equal singular values (sqrt(m) each), but USAGE block-masses decay by Zipf rank (block b carries mass W_b = sum of p over its ranks). The weighted rank-d compression of the kernel faces exactly the dropping-vs-superposing dichotomy of the quadratic theorem, now over blocks:

- when block masses decay steeply (large s), keep-top-d-blocks + drop tail is near-optimal (sparse-exact redux);
- when masses are comparable, superposition (soft mixing of the remaining B-d block directions) is forced, and the EXCESS CE of compression becomes the retrieval-phase quantity: T4 boundary = where compression excess crosses the entropy floor as a function of (B/d, rho, s, n).

Pre-registered T4' target: for fixed (rho, s), the excess-CE phase boundary in (B, d) is sharp (concentration over the kernel ensemble); concrete conjecture: critical d*(B) proportional to the participation ratio of the block-mass sequence (bridging to the E-struct capacity law).

## 8. Excess-CE truncation bound (Pinsker-type; proved 2026-09-19)

**Lemma.** Let z* = log P(.|i) + c_i (any exact logits) and zh any other logit row. Then per-context
KL(P_i || softmax(zh)) <= 2 * max_j |z*_j - zh_j|.
*Proof.* log P_j/Q_j = (z*_j - zh_j) - [logZ(z*) - logZ(zh)], and |logZ(a) - logZ(b)| <= max_j |a_j - b_j| (1-Lipschitz of logsumexp). Hence |log P_j/Q_j| <= 2 max_j |z*_j - zh_j| for every j, and KL = sum_j P_j log(P_j/Q_j) <= sum_j P_j |log(P_j/Q_j)| <= 2*eps_i. □

**Corollary (compression excess).** With zh the best rank-d reachable logits, excess CE <= 2 * E_i[ ||(L^c - L^c_d)_{i,:}||_inf ] — the usage-weighted worst-row deviation of the centered log-kernel from its rank-d truncation. The phase-boundary question is thus a WEIGHTED low-rank approximation problem with an inf-norm (per-row worst-case) metric — sharper than Frobenius and usage-weighted: high-usage contexts demand low row-error.

**Numerical locator (exploratory derivation-support, logged as such; the eventual boundary CLAIM will be pre-registered after the structure is seen): direct CE optimization over (H, W) on a finite planted-block kernel, n = 512, B in {8, 32}, rho in {0.3, 0.7}, s in {0.5, 1.0}, d grid in {2, 4, 8, 16, 32, 64}; Adam, 3 seeds, best-of; measure excess CE vs the entropy floor. Targets: the shape of excess(d) — sharp knee vs gradual — and its dependence on (rho, s) at fixed B.

## 9. Weighted-truncation prediction (pre-registered 2026-09-19 BEFORE the locator data existed; runner launched, results pending)

Mechanism: the centered block-kernel's M-component has B equal singular

values; usage weighting makes the effective importance of block-direction b equal to its usage mass W_b (masses Zipf-ordered across blocks). The optimal rank-d truncation keeps the top-d block directions; by the section-8 lemma,

excess_CE(d) ~= 2 * c_rho * sum_{b > d} W_b (for d < B; ~0 for d >= B),

with c_rho the block-logit coefficient scale (mixture-gap order). Regime shapes this predicts for the locator curves (n=512):

- s = 1.0: excess(d) ~ c * log(B/d) — logarithmic decay, knee at d ~ B;
- s = 0.5: excess(d) ~ c' - c'' * sqrt(d) (tail mass ~ 2(sqrt(B)-sqrt(d)));
- s = 1.5-type (not run; prediction for the extension): excess ~ d^{1-s}.

Falsifiers, frozen: (a) if excess(d) decays smoothly as a single power law in d across BOTH s values with the same exponent, the block-mass mechanism is wrong; (b) if no knee at d ~ B appears, the rank-(B+2) approximability story is wrong; (c) if excess(d) is insensitive to rho, the mixture-gap coefficient story is wrong (it predicts c_rho growing as rho moves off extremes).

## 10. Representability settled (2026-09-19; supersedes the B+2 sketch in 7)

The planted-block kernel yields exactly B distinct conditional distributions (rows within a block identical; outside-part exactly (1-rho)p_j), so the log-kernel has AT MOST B distinct rows: rank exactly B (verified to 1e-15 at four configs; the bumps v_b are disjoint-supported, hence independent). Therefore, untied: exact zero-excess CE representation exists iff d >= B. The earlier "approximately rank-(B+2)" story was answering an irrelevant log-of-mixture question and is retired.

**Row geometry:** row(b) = u + v_b, u = log(1-rho)p (shared), v_b supported on block b only (disjoint across b). Mean-plus-orthogonal-bumps: the leading singular direction is u; the remaining B-1 singular values are ~ sqrt(n W_b)||v_b||-ordered — block usage enters THROUGH the spectrum. The compression problem below d = B is a usage-weighted low-rank fit of B points {u + v_b}; Eckart-Young tail energy beyond rank d is the excess proxy (section-8 lemma converts Frobenius intuition to the CE bound, up to the inf-norm metric gap). The section-9 prediction stands with corrected mechanics: excess(d) tracks tail singular energy, shapes set by the W_b decay, knee at d ~ B (locator already confirms the knee at B = 8: excess 0.126 (d=2) -> 0.051 (d=4) -> 0.0000 (d >= 8)).

## 11. Fisher-metric compression law (2026-09-19; quantitative)

The inf-norm lemma bound overestimates the measured excess 10-30x because KL weights logit deviations by P_ij itself: residual hides where conditional probability is small. The correct second-order object: center each row by its P-expectation and weight entries by sqrt(W_b P_bj) (context mass times conditional mass = the Fisher metric of the softmax model). Then

excess_CE(d) ~= (1/2) * tail Fisher energy beyond rank d (Eckart-Young).

Validation against the locator (rho = 0.3, B = 8):

 s = 0.5: predicted 0.119 / measured 0.126 (d=2); 0.068 / 0.051 (d=4) — agreement within 6-33%. QUANTITATIVE CONFIRMATION in the moderate-skew regime.

 s = 1.0: predicted 0.014 / measured 0.086 (d=2); 0.005 / 0.026 (d=4) — second-order theory underestimates ~6x in the large-deviation regime (higher-order KL terms; and/or optimizer local minima at best-of-3 Adam — unresolved which; the B=32 locator rows and a stronger optimizer will separate them).

Validation matrix extended to rho = 0.7 (locator rows): fisher/measured ratios 1.15 (s=.5,d=2), 0.44 (s=.5,d=4 - optimizer BEATS quadratic theory near the knee: nonlinear CE admits smarter-than-second-order solutions), 3.06 (s=1,d=2 - underestimate far below knee, large-deviation regime), 1.05 (s=1,d=4). Across all 8 measured points: 4 within factor 1.2; deviations regime-structured (underestimate far-below-knee at steep s; possible overestimate near knee). The Fisher law is the leading quantitative object; the nonlinear corrections are bounded and regime-located. rho-sensitivity falsifier (c) survived: excess(0.7)/excess(0.3) = 2.8 at (s=.5,d=2).

## 12. s=1 large-deviation verdict and the exponential-metric obligation (2026-09-19)

Empirical: at (B=8, rho=0.3, s=1, d=2), 12 independent optimizations agree to 0.0005 (best 0.0857) - the optimum is settled and sits 6.2x above the Fisher second-order prediction (0.0139). The optimizer is not the limit; the quadratic expansion is. Mechanism (hypothesis to derive): far below the knee at steep s, ANY rank-d solution leaves O(1) logit deviations on high-mass entries, where KL(P||Q) = E_P[log(P/Q)] costs e^{-delta} - delta - delta^2/2 ~ EXPONENTIAL in the deviation, not quadratic. The correct large-deviation compression functional is an exponential-moment object (E_P[e^{-delta}] subject to the rank-d constraint), reducing to the Fisher form only in the small-deviation regime (which is why s=0.5 far-below-knee agrees and s=1 does not). Deriving the exponential-metric Eckart-Young-type law is the open obligation that would complete T4's compression phase.

## 12b. EXACT IDENTITY: compression = CGF metric (2026-09-19 evening)

For any row, with delta = z - log q (logit residual against the target conditional q):

KL(q || softmax(z)) = log E_q[e^delta] - E_q[delta]

— the CUMULANT GENERATING FUNCTION of delta under q, evaluated as a series: KL = sum_{m>=2} kappa_m(delta)/m!. The Fisher law (section 11) is exactly the kappa_2 term; the s=1 large-deviation gap (6.2x at d=2, 4.7x at d=4) is the higher-cumulant content; the near-knee super-efficiency is the optimizer exploiting cumulant cancellation beyond variance. The complete compression problem is thus rank-d approximation in the CGF metric — an exact, clean formulation. Testable immediately: evaluate the cumulant series at the

settled optima (the 12-seed solutions) and check how much of the 6.2x gap kappa_3 + kappa_4 + ... explains. That numeric check is the next unit; the CGF-Eckart-Young characterization (which rank-d structure minimizes the CGF) is the derivation target that would complete T4.

## 12c. CGF decomposition at the settled optimum — MECHANISM REVISED (2026-09-20; the data contradicts the naive "cumulants add on top" story)

At (B=8, rho=0.3, s=1, d=2), the settled optimum (excess 0.0859, matching the 12-seed 0.0857) decomposes as: quadratic component AT THE OPTIMUM = 0.0966 — SEVEN TIMES the Fisher-optimal quadratic value (0.0139) and ABOVE the true total; kappa_3 = -0.005, kappa_4 = +0.014 partially cancel (truncated series 0.105 vs exact 0.0859). Interpretation: the CGF-metric optimum is NOT the variance optimum plus perturbative corrections — it deliberately accepts ~7x more logit-residual variance to obtain favorable higher-cumulant (negative-skew) structure. The compression metric changes the ARGMIN qualitatively, not just the value. This is the precise sense in which softmax compression is a genuinely different mathematical object from low-rank approximation: variance-optimal projections are strictly suboptimal in KL by large factors in the large-deviation regime. Open: characterize the CGF-optimal residual structure (the negative-skew bias is the visible signature); this is the T4 completion target.

## 12d. The variance-KL envelope and the negative-skew law (2026-09-20)

Per row, KL = log E_q[e^delta] - E_q[delta] depends only on the q-distribution of delta. For FIXED variance v = Var_q(delta), the distribution minimizing KL is the solution of a moment problem: minimize log E e^delta s.t. E delta = 0, Var = v. The extremal is TWO-POINT (convex moment problem; extremal distributions are supported on <= 2 points):

delta = -alpha w.p. 1-pi, delta = +beta w.p. pi,

alpha = pi*theta, beta = (1-pi)*theta, theta = sqrt(v/(pi(1-pi))),

with KL*(v) = min_pi log( (1-pi) e^{-pi theta} + pi e^{(1-pi) theta} ).

Small-v calculus: expanding in theta, the optimum has pi -> small... the envelope satisfies KL*(v) = v/2 - c v^{3/2} + O(v^2): the quadratic term is UNAVOIDABLE (matches: even the best cumulant structure cannot beat v/2 at leading order) but the discount is Theta(v^{3/2}), achieved by LEFT-SKEWED residuals with third cumulant kappa_3* = -c' sqrt(v) * v = -c' v^{3/2}-scaled — the measured kappa_3 = -0.0053 at the settled optimum is this signature. CONSEQUENCE: the CGF optimum accepts variance v_O ~ 7x the Fisher value v_F exactly when the envelope discount makes it worthwhile: v_O/2 - c v_O^{3/2} < v_F/2 requires v_O within the envelope's validity ball — the observed 6.2x/4.7x ratios are envelope quantities, computable from c. Obligations: exact c from the pi-optimization; numeric verification of the predicted v_O and kappa_3* against the settled optima; then the rank-d-constrained envelope (the true T4 compression law).

## 12e. CORRECTION: the envelope is degenerate; KL compression lives on the exponential Orlicz scale (2026-09-20)

Numerical pi-optimization of the two-point envelope shows the optimizer at the BOUNDARY (pi* -> 1): rare huge negative jumps (probability eps -> 0, magnitude ~ sqrt(v/eps) -> infinity) carry the variance while E_q e^delta -> 1, giving inf KL = 0 AT ANY FIXED VARIANCE. The v/2 - c v^1.5 discount law of 12d is WRONG (withdrawn): the moment problem with only variance fixed is degenerate. The correct statement is stronger and cleaner:

**KL compression is not governed by polynomial moments of the logit residual at all — it is governed by the exponential moment E_q[e^delta] (one-sided Orlicz scale).** Variance can be made arbitrarily large at negligible KL cost (negative tail), and arbitrarily small KL damage still requires controlling the POSITIVE exponential tail. This explains all three measured regimes at once: (a) the s=0.5 Fisher agreement (small-deviation regime where all metrics coincide); (b) the s=1 6x gap with 7x accepted variance (variance is the wrong statistic; the optimizer reshapes the exponential tail); (c) near-knee super-efficiency (positive-tail mass relocated to vanishing-q entries where e^delta is cheap).

**T4 completion target (final form): an Eckart-Young-type theorem for rank-d approximation in the exponential-Orlicz metric log E_q e^delta — a functional-analytic object with no quadratic analogue, and the precise sense in which softmax compression is a genuinely different mathematical object.**

## 12f. The DV-duality core of Orlicz compression (2026-09-20)

Gibbs/Donsker-Varadhan: log E_q[e^delta] = sup_mu [E_mu delta - KL(mu||q)]. Hence per row (and summed with context weights w_i):

excess CE(Z) = sup_{mu_i} SUM_i w_i [ E_{mu_i} delta_i - E_{q_i} delta_i - KL(mu_i || q_i) ],
delta_i = z_i - log q_i, Z = W^T H rank-d.

First-order optimality over the factors (H, W): the gradient of the objective at the dual optimum involves (mu*_i - q_i) — i.e., the Fisher metric of the quadratic law is REWEIGHTED by the tilted measure mu*, and the optimal Z is an SVD-like solution in the mu*-weighted metric. Self-consistency: mu* itself depends on delta hence on Z.

**T4 final formulation.** The rank-d Orlicz-compression optimum is a self-consistent tilted SVD: find (Z, {mu_i}) with Z the top-d mu-weighted-Fisher factorization of the centered log-kernel and mu_i the DV-tilt of the residual. Conjectured phase structure (to prove):

- near-representability fixed point: mu* = q (tilt degenerate) -> the Fisher law of section 11 (validated there);
- far-below-knee at steep s: a second fixed point with mu* concentrated on the bump heads (positive-residual entries) -> the 6x/4.7x regime, with the variance acceptance and negative skew as its measurable signatures (sections 12c, 12e);

 the T4 phase boundary = where the second fixed point overtakes the first,
as a function of (d/B, rho, s).
Obligations: (i) rigorous statement of the fixed-point map and its
optimality (nonconvexity handled via the DV sup being exact per Z);
(ii) solve the two fixed points in the block-kernel asymptotics;
(iii) pre-registered numeric verification of the boundary.

## 12g. Rigorous first-order characterization (obligation i, step 1; 2026-09-20)

Reduction: the kernel has B distinct conditionals, so the problem is
minimize Phi(R) = sum_b W_b KL(q_b || softmax(r_b)) over B x n matrices R
of rank <= d (the full n x n logit matrix is the block-indicator lift of R,
preserving rank).

Gradient: grad_{r_b} KL(q_b||softmax(r_b)) = softmax(r_b) - q_b = rho_b - q_b
(classical). First-order optimality on the rank-d variety: the gradient
field must lie in the TANGENT space at R* (orthogonality to the variety's
normal cone), i.e.

** the gradient field vanishes on rowspace(R*): U U^T G = 0 and
G V V^T = 0, i.e., G lives entirely in the complement block **

— the direct analogue of Eckart-Young's residual-orthogonal-to-
approximation structure. (CORRECTED 2026-09-20: the original statement had
the containment direction reversed; the numerical check below exposed it.) This is a projected-gradient fixed point, exact and
first-order-necessary (nonconvexity: not sufficient; global optimality
needs the second-order/comparison argument — obligation continues).
Structure reading:

 Fisher law = the LINEARIZED fixed point: rho ~ q + q-residual (delta),
gradient ~ W_b q_b-compounded delta, condition reduces to the weighted
SVD projection of section 11 (validated regime).

 Tilted regime = the NONLINEAR fixed point: rho* differs from q by the
exponential tilt on positive-residual entries; the condition forces the
row space to capture the tilt direction — the negative-skew/variance-
acceptance signatures of 12c follow.

 The earlier alternating scheme failed because it reweighted the METRIC
instead of imposing this tangent condition; a valid solver = projected
gradient on Phi with rank-d projection (guaranteed stationarity, the
same optima the SGD found).

## 12h. Numerical verification of the corrected condition (2026-09-20)

At the settled optimum (B=8, rho=0.3, s=1, d=2; the 12-seed solution):
off-space energy of the gradient field G_b = W_b(softmax - q) relative to
rowspace(R*) = 1.0000 — the gradient lies ENTIRELY in the complement block.
The settled optimum satisfies the first-order condition exactly (to
numerical precision), confirming: (a) the corrected 12g condition;
(b) that the SGD optima are true stationary points of the rank-d problem;
(c) the Eckart-Young-type orthogonality structure survives the Orlicz
metric at the optimum. The tilted fixed point of 12f is THIS solution's

nonlinear regime — its characterization now has a verified first-order core.

## 12i. Dual-bound attempt: withdrawn, with structural lesson (2026-09-20)

The DV-based dual bound (fix mu, minimize the linearized inner problem by an anti-aligned top-d SVD) is INVALID: the inner problem is linear in R on the UNBOUNDED rank-d variety, so its infimum is -infinity unless the coefficient field vanishes; the closed form used applies only to nuclear-norm-CONSTRAINED variants. Structural lesson (recorded as content, not just error): KL compression intrinsically lacks the norm geometry that powers Eckart-Young duality — logits can scale freely because only entropy differences matter. Any T4 optimality theory must either (a) work directly with the softmax-intrinsic boundedness (probability simplexes, not logit balls), or (b) adopt an explicitly regularized (weight-decay) variant where norm geometry exists. Both routes noted; global optimality remains open with stationarity verified.

## 12j. Strict local minimality CERTIFIED (2026-09-20)

Analytic-gradient Lanczos (45 iterations) on the 1040-dimensional factor space at the settled optimum: lambda_min = 2.4e-05 > 0, lambda_max = 0.252. The optimum is a certified strict local minimum. The near-flat direction (lambda_min three orders below lambda_max) explains the tight 12-seed reproducibility (0.0005 spread): a shallow but positive valley. Status of the T4 optimality stack at (B=8, rho=0.3, s=1, d=2): stationarity exact (12h), strict local minimality certified (this section), global optimality open with the dual route structurally unavailable (12i).

## 12k. Regularized-dual route vacuous (2026-09-20; third and final duality attempt)

With lambda||R||_F^2 added, the inner dual problem is strictly convex with closed form (-sum sigma_i^2/(4 lambda)) and the DV bound valid. But the settled optimum carries ||R||_F^2 ~ 1.1e4: any lambda small enough to leave the problem unchanged makes the bound vacuous (0.41 vs 10930 feasible at lambda=1). The optimum lives far from every useful norm ball — the KL geometry is intrinsically norm-free there. SUMMARY OF CERTIFICATION ATTEMPTS: (1) metric-reweighting scheme - invalid; (2) unconstrained dual - unbounded inner; (3) regularized dual - vacuous at meaningful lambda. Standing result: strict local minimality certified + exact stationarity + multi-seed reproducibility. Global optimality is open and appears to resist duality for structural reasons; simplex-native formulations are the one untried route.

## 12l. Certificate correction (2026-09-20; review-7 challenge verified)

The 12j "certified" status is downgraded to EVIDENCE-GRADE: (a) GL(d) factorization orbits are exact zero modes (verified numerically at FD-noise level); (b) my colshift quotient basis was wrong — softmax column-shift

invariance does NOT descend to a factor-space gauge (rank constraints block it; the corresponding directions carry genuine O(1) curvature); (c) the correct 4-dim GL(d)-quotient Lanczos gives lambda_min = 1.18e-05, positive but at the FD-Hessian noise boundary. Standing: positive curvature in every computation (full-space 2.4e-05; quotient 1.18e-05; both far below the 0.25 spectral max — a genuine four-order near-flat valley), but a rigorous certificate requires an analytic or autodiff Hessian. The near-flat valley conclusion (explaining seed reproducibility) is robust.

## 13. Candidate B specification (drafted 2026-09-21 for review adjudication)

Family: hierarchical block kernels with GROWING block count B(d) (block tree of depth L, block masses decaying by level; B(d) ~ d^beta) and stochastic-block variants (random graph kernels, no construction-forced knee).

Observable (gauge-invariant, per reviews 2/7): the OPTIMAL LOSS CURVE excess_CE*(d) and its distortion geometry — never factor spectra. The centered logit operator of the kernel is the intermediate object; its Fisher-metric spectrum enters only through the validated second-order law.

Program (derivation before simulation): (i) compute the centered-logit and Fisher spectra of the hierarchical family analytically (block-tree structure makes the SVD recursive — closed forms plausible); (ii) predict excess_CE*(d) for d both below and above the effective block count, using the Fisher law in its validated regime and the CGF/large-deviation theory outside; (iii) derive the phase boundary in (beta, rho, s) where superposition (d < effective rank) stops being viable at given excess; (iv) only then pre-register the simulation. The distinctive content vs the planted-block cycle: the knee is emergent (growing kernel), not construction-forced, answering review-6's cheapest-confound objection.

## 13b. Obligation (i) started: the hierarchical SVD structure (2026-09-21)

Level-mixture kernel: P(j|i) = (1-rho)p_j + rho sum_ell pi_ell 1[i, j share a level-ell ancestor], b-ary tree depth L, level masses pi_ell decaying. Distinct conditionals = finest blocks (b^L rows types).

**Nested-bump orthogonality (lemma, easy).** The row map sends block b' at level ell to a bump vector v_{b'} supported on b"s descendant tokens. Bumps at the SAME level have disjoint supports (orthogonal); bumps at DIFFERENT levels are nested but their CENTERED versions (row-mean removed) are orthogonal to coarser-level bumps when the coarser bump is constant on the finer block (the tree property: a level-(ell-1) bump is constant across each level-ell child block). Hence the centered log-kernel decomposes as an ORTHOGONAL sum over levels, with per-level rank (b-1) b^{ell-1} and per-direction scale set by the pi_ell mixture gaps and the within-level mass profile.

**Consequences (to be completed):** (a) the centered-logit SVD is level-block-diagonal: singular values come in level bundles of

multiplicity (b-1)b^{ell-1} with level scales — a power-law spectrum arises when pi_ell decays geometrically (each level contributes a decade); (b) rank-d truncation = level selection (whole levels in order of scale) plus within-level partial truncation — excess_CE*(d) is a STEPWISE-plus-refinement curve; (c) the emergent knee: superposition cost becomes nontrivial exactly when d crosses the cumulative level ranks — growing with L, not construction-pinned to a single B. This is the derivation target: closed-form excess_CE*(d) with an emergent, tunable knee.

## 13c. Bundle-scale law (2026-09-21; matched to the measured bundles)

Level-ell directions are the tree Haar vectors (centered block indicators) at level ell. Their Fisher-weighted scale:

sigma_ell ~ sqrt(m_ell) * Delta_ell,

m_ell = the usage mass captured by level-ell splits, Delta_ell = the level-ell logit gap (mixture log-ratio the level contributes). With geometric pi decay, Delta_ell decays geometrically -> bundle scales geometric in ell, MATCHING the measured bundles (50 -> 26 -> ~9 -> ~3 -> ~1.4 avg for pi_decay = 1/2; ratio ~ 1/2 per level after the mass factor). With power-law pi (pi_ell ~ ell^{-t}), the envelope is a power law in the cumulative rank — the family spans power-law spectra with TUNABLE exponent through t, connecting to the real-model exponent range. The excess curve: excess_CE*(d) for d between cumulative level ranks R_ell = sum_{l<=ell} (b-1)b^{l-1} is dominated by the DROPPED levels' total Fisher tail — stepwise with refinements inside bundles. Closed-form status: envelope law derived (this section); exact within-bundle refinement pending; the CGF (large-deviation) version beyond the Fisher regime pending.

## 13d. The recursive-tail excess curve (2026-09-21)

Within a level-ell bundle, the (b-1)b^{ell-1} Haar directions carry scales ordered by their block usage masses (larger-mass blocks -> larger sigma; matches the measured within-bundle ordering). Truncation inside a bundle keeps high-mass blocks first, so the WITHIN-bundle excess tail is the block-mass tail law of the planted-block cycle (validated there), at level scale Delta_ell^2. The complete Fisher-regime excess curve is therefore a RECURSIVE DOUBLE TAIL:

excess_CE*(d) ~ sum_{ell beyond kept levels} [level-ell total Fisher energy] + sum_{kept ell} [ Delta_ell^2 x (block-mass tail beyond the kept within-bundle directions) ]

- across levels: geometric or power-law envelope set by pi decay;
- within levels: Zipf block-mass tails set by s.

The hierarchical family thus interpolates the two validated regimes of the whole program (planted-block tails; Fisher two-regime law) in one object with an EMERGENT knee, and its (pi decay, s) plane spans the real-model exponent range. Remaining: CGF-regime version, the phase boundary

statement, and the pre-registered simulation (in that order).

## 13e. CGF-regime crossover for the hierarchical family (2026-09-21)

The recursive-tail curve (13d) is the second-order envelope. Its validity
regime, per the 12-series findings: the Fisher law holds when the residual
logit deviations are small; in the hierarchical family the dropped-level
residuals carry deviations of size ~ Delta_ell (the level's logit gap).
Crossover condition: the second-order curve is trustworthy for the levels
where Delta_ell is small (deep, weakly-weighted levels); it UNDERESTIMATES
(measured 4.7-6.2x on the planted-block analogue) for strongly-gapped
dropped levels (coarse levels with large rho pi_ell). The full prediction:

excess_CE*(d) = recursive-tail (13d) for small-gap drops
+ CGF-corrected (tilted) excess for large-gap drops,

with the tilted solutions exhibiting the measured signatures (variance
acceptance, negative skew). The phase boundary in (pi decay, rho, s):
where the large-gap-dropped regime begins to dominate the excess — i.e.,
where the last strongly-gapped level falls below the truncation rank.
This completes the derivation program; the pre-registered simulation
(targets: stepwise curve + within-bundle tails + crossover location)
awaits only the review's verdict on opening the cycle.

## 13f. Empirical cycle results (2026-09-21; post construction-fix)

Corrected kernel (root-inclusive tree; rank 32 representability): P1
REFUTED — the excess curve is smooth log-convex steepening to EXACT zero
at d = 32, not a staircase (the emergent knee is a steepening tail).
P2 PASS — log-convex throughout (decay ratios 1.2 -> 18 increasing).
P3 REFUTED at this configuration — no rho-amplified CGF gap; the Fisher
recursive-tail envelope is TIGHT (1.08-1.28x) far below representability
in BOTH rho arms, with the now-familiar super-quadratic efficiency near
the knee (ratios to 0.02). Net: the two-regime structure generalizes
across kernel families; the stepwise and CGF-embellishment predictions
fail at pi-decay 1/2. Steeper-pi cells are the natural probe for whether
the CGF regime is reachable in this family.

## 13g. Steeper-pi probe: DISJOINTNESS gates the CGF regime (2026-09-21)

Pre-registered probe (pi_decay 0.25/0.125, rho 0.3/0.7, d 2/5/11): the
hierarchical family does NOT reach the large-deviation regime at any tested
steepness (max measured/Fisher ratio 1.61 vs the 1.8 reachability
threshold; all other cells 0.14-1.43). Mechanism: every token pair shares
the root, so mixture probabilities never develop the extreme contrasts of
disjoint blocks — logit gaps stay bounded as pi steepens. CHARACTERIZATION:
the compression-law regime is governed by the kernel's OVERLAP GEOMETRY —
nested (hierarchical) kernels live in the Fisher regime at all parameters;
block-disjoint kernels reach the CGF regime. The two-family picture is
complete: Fisher two-regime law universal; CGF regime = disjointness-gated.

Family closed.

# HP-E: The Aggregate Interference Hierarchy Theorem

Status: OPENED 2026-09-19 (review-5 ranked this the lead unit; HP-D paused for representability/information-model repair — see HPD §6 addendum). Math-first; this document carries the statements, the upper-bound derivation, and the lower-bound program. Nothing here is claimed proved until marked.

## 0. Why aggregate (the review's point, formalized)

Per-term d^{-(t-1)/2} suppression of individual t-body interference terms is a standard bilinear/tensor concentration fact. The high-dimensional content lives in the AGGREGATE: with k = k(d) superposed features, the number of t-body terms is C(k, t) ~ k^t/t!, so total t-body interference energy scales like

A_t(k, d) ~ C(k, t) · d^{-(t-1)} (heuristic),

and the t-body channel is negligible iff k □ d^{(t-1)/t}. The theorem target is this phase boundary WITH matching lower bounds.

## 1. Setting (fully specified)

□ Features: f_1, …, f_k □ S^{d−1} (unit sphere), independent isotropic subgaussian directions (random-feature ensemble; structured features are the HP-E2 extension).

□ Signal model: degree-p polynomial readout φ(x) = Σ_{|S| ≤ p} T_S □x□^S with fixed coefficient tensor T, normalized so that the diagonal (1-body) signal terms have O(1) energy: E[T_{ii}(f_i·f_i)-type terms] = Θ(1), and each coefficient block normalized ‖T_S‖_F = Θ(1) (normalization fixed below per lemma; changing it rescales constants, not thresholds — to be verified).

□ Observable: input x = Σ_{i≤k} c_i f_i (superposition of k unit features, coefficients c_i = Θ(1)).

□ Interference channel t: the collection {T_S □x□^S : |S| = t, S cap-free} (subsets of distinct feature indices, t ≥ 2). Total interference energy A_t = Σ_{|S|=t} |T_S □x□^S|².

## 2. Theorem statements

**E1 (exact aggregate mean).** For random isotropic features, E[A_t] = C(k, t) · E_single(t) with E_single(t) = Θ(d^{-(t-1)}) (each t-body term's squared magnitude has expectation Θ(d^{-(t-1)}) under the normalization above). Hence E[A_t] = Θ(k^t / (t! d^{t-1})).

**E2 (upper bound / negligible phase).** With probability ≥ 1 − δ, A_t ≤ C(ε) · k^t/(d^{t-1}) provided the t-body terms' correlation structure permits second-moment control: Var[A_t] = o(E[A_t]²). Route: A_t is a sum of C(k,t) weakly-correlated positive quadratic forms; bound pairwise covariances via isotropic fourth/sixth-moment tensors. Corollary: if

$k \le \varepsilon \cdot d^{(t-1)/t}$ then $A_t \le C(\varepsilon) \cdot \varepsilon^{t} \cdot$ (1-body signal) — the degree-p readout's t-channels are collectively negligible: the mean-field (independent-feature) approximation is valid.

**E3 (lower bound / failure phase — the novel obligation).** There exist (i) a coefficient tensor T and (ii) constant-probability feature draws, such that for $k \ge C \cdot d^{(t-1)/t}$, $A_t \ge c \cdot$ (1-body signal): aggregate t-body interference is inescapable for ANY degree-p readout normalized as above. Route: Paley–Zygmund on $A_t$ (needs E3a: $\mathrm{Var}[A_t] \le C \cdot E[A_t]^2$ — the same second-moment bound as E2, giving concentration BOTH ways), or an explicit adversarial construction (align coefficient tensor with realized feature correlations — weaker, since T is fixed before the draw; the random-T-average route may be needed: state precisely which quantifier order the theorem claims).

**E4 (capacity ladder — the phase diagram).** Combining E2+E3 across $2 \le t \le p$: the mean-field regime for degree-p computation on k superposed isotropic features holds iff $k = o(d^{(p-1)/p})$; it fails (with matching constants) at $k = \Omega(d^{(p-1)/p})$. Sanity anchors: $p=2 \to k^* = \Theta(\sqrt{d})$ (recovers coherence/JL-flavored capacity); $p=3 \to \Theta(d^{2/3})$; $p \to \infty \to k^* \to d$. HD-native reading: $d^{(p-1)/p}$ is the dimension-dependent capacity frontier of degree-p mean-field computation — a sharp, matching-bounds phase law.

## 3. Upper-bound derivation (E1 + E2 upper route, done to be checked)

Quadratic case t=2, p=2 (anchor; generalizes): $T = M \in R^{d \times d}$, $\|M\|_F = 1$; $x = f_1 + f_2$; cross term = $f_1^T M f_2$. $E[(f_1^T M f_2)^2] = \mathrm{tr}(M\, E[f_2 f_2^T]\, M\, E[f_1 f_1^T]) = \mathrm{tr}(M (I/d) M (I/d)) = \|M\|_F^2/d^2$ — wait: isotropic unit vectors have $E[ff^T] = I/d$, so $E = \mathrm{tr}(M M^T)/d^2 = 1/d^2$?? — per-PAIR variance $\Theta(d^{-2})$, not $d^{-1}$. NOTE (honest flag): the entry-117 "RMS $O(1/\sqrt{d})$" used $E[ff^T] = I$ (unnormalized Gaussian vectors, norms $\sqrt{d}$). NORMALIZATION MATTERS (review-3's point, now biting): with unit-norm features the per-pair RMS is $\Theta(1/d)$ and $A_2 = \Theta(k^2/d^2) \to$ threshold $k^* = \Theta(d^{1} \cdot ?)$ — recompute: $A_2 \sim k^2/d^2$ negligible iff $k \ll d$. With Gaussian ($\sqrt{d}$-norm) features: per-pair RMS $\Theta(1/\sqrt{d})$ — but then 1-body terms carry norm-$d^4$ factors... The ladder E4's exponents DEPEND on the ensemble normalization: the theorem must fix ONE convention (proposal: unit inputs $x = \Sigma\, f_i/k^{1/2}$ power-normalized, tensor spectral-normalized) and derive everything within it. OBLIGATION E0 (new, first): recompute the anchor under the fixed convention and restate the ladder exponents; do not carry entry-117's mixed conventions forward.

## 3b. E0 RESOLVED (2026-09-19): the convention and the exact anchor

**Convention (fixed):** features $f_i$ independent isotropic UNIT vectors ($E[ff^T] = I/d$); readout tensor normalized to the trace scale — for degree 2, M with $\|M\|_F^2 = \Theta(d)$ and $\mathrm{tr}\, M = \Theta(d)$ (e.g., $M = I$), so the per-feature diagonal channel is $\Theta(1)$ EXACTLY ($f^T I f = 1$). Entry-117's mixed conventions are retired: its $O(d^{-1/2})$ implicitly meant THIS regime.

**Exact t=2 anchor (E1 for t=2, proved):** for i ≠ j,
E[(f_i^T M f_j)²] = tr(M(I/d)M(I/d)) = ‖M‖_F²/d², hence
E[A_2] = k(k−1)‖M‖_F²/d² = Θ(k²/d) at the convention. Signal channel
Σ_i E[(f_i^T M f_i)²] = Θ(k). Negligibility A_2 = o(signal) iff k □ √d
(up to tr constants): **k*(d) = Θ(√d) under the fixed convention.** The
earlier apparent vanishing of the hierarchy at unit norms was a tensor-scale
artifact; the convention above is the one under which "mean-field = diagonal
channel dominates" is the right question.

## 3c. E1 for degree 3 and the CRITERION BIFURCATION (2026-09-19)

Expansion of the trilinear readout on x = Σf_i: T[x,x,x] = Σ_{i=j=l} T[f_i]³
(signal) + Σ_{two-same} T[f_i,f_i,f_j] + Σ_{all-distinct} T[f_i,f_j,f_l].
Per-term variances under the §3b convention (Gaussian/sphere, Wick):

- mixed-pair (two-same) channel: E[T[f_i,f_i,f_j]²] = Θ(1/d) (one cross contraction) — same order as degree-2 pairs;
- all-distinct triples: E[T[f_i,f_j,f_l]²] = Θ(1/d²) (two independent cross contractions) — RMS d^{−1} = d^{−(t−1)/2} at t=3. Ladder confirmed in expectation; general-t conjecture unchanged.

**Criterion bifurcation (must be explicit in E4 — this changes the headline):**

- ABSOLUTE mean-field validity (φ(Σf_i) = Σφ(f_i) + o(1)): requires A_t = o(1) □t, i.e. k^t/d^{t−1} = o(1) → **k = o(d^{(p−1)/p})** — the ladder, sublinear, binding at t=p.
- RELATIVE validity (error o(signal), signal = Θ(k)): k^t/d^{t−1} = o(k) → **k = o(d)** for every t — no ladder.

Both are legitimate theorem statements; the ladder (absolute) is the sharper
HD content (capacity below d). E4 will state both, ladder as headline with
the criterion named. (Self-caught before review; recorded.)

## 3d. E2a skeleton: variance of A_2 (concentration both ways)

A_2 = Σ_{i≠j} Z_ij², Z_ij = f_i^T M f_j. Pair covariance structure:

- disjoint index pairs: independent, covariance 0;
- pairs sharing one index (i,j),(i,l): conditioning on f_i,

Cov = Var_fi(‖M^T f_i‖²)/d² = O(‖M‖_F⁴/d⁴ · c) = O((EZ²)²·c/d)-order;
count of such overlapping pairs: O(k³).
So Var[A_2] = O(k³ · E²/d) with E = ‖M‖_F²/d², giving Var[A_2]/E[A_2]² =
O(k³ E²/d)/(k⁴E²) = O(1/(kd)) □ 1 whenever k ≥ 1 — A_2 concentrates around
its mean with room to spare (constants and the sphere-vs-Gaussian moment
terms to be pinned in the write-up; the O(c/d) per-pair covariance decay is
the load-bearing step — it is where isotropy enters quantitatively).
E3's Paley–Zygmund route then needs the same bound (two-sided
concentration), giving A_t = Θ(E[A_t]) w.h.p. — the failure phase at
k = Ω(d^{(p−1)/p}) follows from E[A_t] = Ω(1) + concentration. Quantifier
order for E3 (fixed T before the draw vs averaged T) still to be fixed;
the averaged-T version is provable by this route; the fixed-T version needs
the covariance bound uniform over T (operator-norm conditions).

## 3e. General-t E1 lemma (Wick pairing statement; proof skeleton)

**Lemma E1-general (CORRECTED 2026-09-19 after the E5 simulation refuted the registered d^{t-1} scaling; see §3f).** Let T be a fixed coefficient tensor and f_1, …, f_t independent uniform unit vectors. Then

$$E[T[f_1, \ldots, f_t]^2] = \|T\|_F^2 / d^{t} + \Lambda(T, d),$$

(each of the t vectors pairs its own two slot factors, contributing 1/d each; the original d^{t-1} was wrong and the simulation measured the d^t law to the digit: pair^2 x d^2 = 1, triple^2 x d^3 = 1 up to noise).

where the remainder Λ collects the trace-type Wick pairings that pair slots filled by the SAME vector; each such pairing contracts two slots of T along the diagonal, contributing terms of the form ‖contraction of T‖²_F / d^{t−1} with additional 1/d-type factors relative to the leading term when $t \geq 3$. In particular, if all slot-pair contractions of T are bounded by (1−ε)-fractionally smaller than ‖T‖_F² (genericity condition on T), then $E[T[f_1,\ldots,f_t]^2] = \Theta(\|T\|_F^2/d^{t-1})$.

*Proof skeleton.* Expand the square as a double sum over slot-index tuples α, β: Σ T_α T_β E[Π_r f_{r,α_r} f_{r,β_r}] (r indexes the t distinct vectors). For each vector f_r, the moment E[Π over its 2m_r slot factors] vanishes unless its slot multiset pairs up; uniform-sphere moments give pair-products δ/d and higher corrections O(1/d^{1+m_r}). The leading Wick structure pairs α_r with β_r within each vector, yielding (1/d)^{Σ m_r} Σ_α T_α² with Σ m_r = t — giving ‖T‖_F²/d^{t−1} minus the corrections where pairings CROSS slots within a vector, which produce the diagonal contractions collected in Λ. □ (details to be written out; the t=2 case is §3b's exact identity with Λ = 0.)

**Corollary (RESCOPED after the correction).** The Θ(1) diagonal signal channel is SPECIAL to quadratic projection structure (M = Σ v_l v_l^T with orthonormal {v_l} gives f^T M f = 1 exactly); single-vector moment structures do not provide a Θ(1) t=1 channel at degree $t \geq 3$ (e.g. the diagonal cubic tensor gives Σ_a f_a³ with variance Θ(1/d)). Therefore:

- the aggregate ladder k* = Θ(√d) is PROVED and validated for quadratic/energy (projection-structured) readouts only;
- the degree-p extension is OPEN and requires a new signal model for what "computing k features with one degree-p form" means — the obstruction (no natural Θ(1) diagonal channel at $t \geq 3$) is now explicit;
- candidate routes: (a) multi-family readouts (slots indexed by different feature families with cross-family orthogonality), (b) structured-feature extension (E-struct: covariance/effective-rank replacing d, per review-5 move 3), (c) restrict the program's capacity claims to the quadratic class, which is the class real attention/logit bilinears live in.

## 4. Proof obligations (ordered, updated)

E0: DONE. E1 general-t: stated §3e, write-up pending. Remaining:

E0: DONE (§3b). E1 degree-3 channel: DONE in expectation (§3c); general-t

exchangeability write-up pending. E2a skeleton: §3d; constants pending.

Remaining:

E1: exact E[A_t] under the convention (exchangeability argument).

E2a: Var[A_t] ≤ C E[A_t]² (correlation structure of t-body squares).

E2b: conclude negligible phase.

E3: failure phase with explicit quantifier order (fixed-T vs averaged-T).

E4: assemble the ladder with matching constants.

E5 (later, pre-registered): numeric spot-check arm at (d, k) points straddling the predicted boundary, BEFORE any claim leaves this document.

## 5. Relation to the mission

A matching-bounds capacity frontier k*(d) = Θ(d^{(p-1)/p}) for degree-p mean-field computation is a dimension-dependent invariant of the kind the axiom demands: it does not exist in low dimension (all k □ d regimes are mean-field there), it is ensemble-explicit, and it directly quantifies when "almost-orthogonal packing" stops paying for computation. It also gives the correctly-specified foundation the reviewer demanded for any later capacity claim about real representations.

## 3f. E5 anchor validation RESULTS (2026-09-19; runner

experiments/run_hpe_anchor_check.py; data results/hpe_aggregate/)

Pre-registered verdicts (P1-P4 frozen in the runner header before the run):

□ P1 (E[A_2] = k(k−1)/d within 5%): formal FAIL — 8/9 cells within 0.5-4.6%, one small-k cell (d=128, k=4) at 13% (finite-size; mean 0.082 vs 0.094). Substantively confirmed at k >= sqrt(d)/2.

□ P2 (concentration cv <= 5/sqrt(k)): PASS (max cv 0.66 at k=4 vs bound 2.5).

□ P3 (random-tensor ladder ratios in [0.5,2]): FAIL — and the failure is a THEORY correction, not noise: measured pair²·d = 1/d and triple²·d² = 1/d exactly, i.e. E[term²] = ‖T‖_F²/d^t (per-vector 1/d pairing), not the registered d^{t-1} power. Lemma E1-general corrected accordingly.

□ P4 (A_2 crosses 1 near k = sqrt(d)): PASS (0.87-0.97 at k≈sqrt(d); 0.04-0.05 at sqrt(d)/4; 14.8-15.7 at 4·sqrt(d)).

Net: the quadratic anchor is proved AND empirically validated (P1*, P2, P4); the general-t extension was refuted in its registered form and rescoped — the ladder is quadratic-specific until a degree>=3 signal model exists.

## 3g. E-STRUCT LEMMA (derived 2026-09-19): anisotropic capacity = participation ratio

**Setup.** Features f_i = sqrt(d/tr(Sigma)) * Sigma^{1/2} u_i with u_i uniform unit vectors (so E||f_i||^2 = 1: unit-energy features); quadratic energy readout. Per-pair interference:

E[(f_i . f_j)^2] = (d/tr Sigma)^2 * tr(Sigma^2)/d^2 = tr(Sigma^2)/(tr Sigma)^2 = 1/PR(Sigma),

where PR = (tr Sigma)^2/tr(Sigma^2) is the covariance participation ratio.

Checks: isotropic Sigma = I -> 1/d (PR = d, k* = sqrt(d), recovers 3b);

rank-1 Sigma -> 1 (PR = 1, k* = 1: parallel features maximally interfere).

**E-struct Theorem (quadratic class; expectation level).** For unit-energy

anisotropic features the aggregate interference reaches order one at

k = Theta(sqrt(PR(Sigma))) [absolute criterion];

the RELATIVE criterion (A_2 = o(signal), signal = Theta(k)) crosses at k = Theta(PR(Sigma)). Dimension enters only through PR at the expectation level; high-probability statements are proved only for the isotropic case (review-6 scoping).

**Corollary (power-law spectra — the program's bridge).** For Sigma = diag(l^{-alpha})_{l<=d}:

- alpha < 1/2: PR = Theta(d) -> k* = Theta(sqrt d) (isotropic-like);
- alpha = 1/2: PR = Theta(d/log d);
- alpha > 1/2: PR = Theta(d^{2-2alpha}) -> **k* = Theta(d^{1-alpha})**.

Trained geometries in the record (alpha ~ 0.5-0.9) therefore sit at capacity frontiers d^{0.1}..d^{0.5}: a power-law spectrum taxes quadratic mean-field computation by d^{alpha-1/2} relative to isotropy. This is the lawful connection between spectral exponent and computation capacity the program has been hunting — spectrum -> capacity, not spectrum -> fitted slopes.

**Pre-registered numeric check (frozen before running):** simulate unit-energy features with power-law Sigma at alpha in {0, 0.5, 0.75, 0.9}, d in {512, 2048}; predicted per-pair mean f_i.f_j squared = 1/PR(alpha, d) (exact formula, no free constants); predicted A_2 crossing of 1 within a factor sqrt(2) of sqrt(PR). PASS if per-pair means within 10% and crossings within the factor-2 band across 8/8 (alpha, d) cells.

## 3h. THE ISOTROPIC QUADRATIC THEOREM, COMPLETE (2026-09-19)

For unit-norm independent isotropic features and M = I (energy readout):

**Exact mean.** E[A_2] = k(k-1)/d (3b, validated).

**Exact variance (CORRECTED 2026-09-19, review-6: A_2 = sum over ordered pairs counts (i,j) and (j,i), which are IDENTICAL for M = I).** Write A_2 = 2 * sum_{i<j} W_ij with W_ij = Z_ij^2. For each unordered pair: E[Z^4] = 3/(d(d+2)), E[Z^2] = 1/d, so Var(W) = (2d-2)/(d^2(d+2)). Covariances between unordered pair-squares vanish identically (share-one-index: E[Z_ij^2 Z_il^2] = E_fi[(1/d)(1/d)] = E[Z^2]^2 by conditional independence and ||f_i|| = 1; disjoint: independent). Hence

Var(A_2) = 4 * C(k,2) * (2d-2)/(d^2(d+2)) = 2k(k-1)(2d-2)/(d^2(d+2)), cv(A_2) ~ 2/k (previously stated sqrt(2)/k - low by factor sqrt(2); the two-phase conclusion is unchanged, constants corrected).

**Two-phase conclusion (E2 + E3 for the isotropic quadratic class, proved).** By Chebyshev, A_2 in [E/2, 2E] with probability >= 1 - 8/k^2. Therefore:

- k = o(sqrt(d)): A_2 = o(1) w.h.p. — mean-field (independent-feature) energy readout valid;
- k = Omega(sqrt(d)): A_2 = Omega(k^2/d) = Omega(1) w.h.p. — aggregate interference inescapable.

Capacity frontier k* = Theta(sqrt(d)) with matching bounds and explicit constants, quadratic/projection class. Simulation agreement: cv predicted

sqrt(2)/k vs measured 0.031-0.058 at k = 45 (higher-cumulant tail; same order).

**Remaining for the full E-struct theorem:** the anisotropic variance identity (unit-energy features should inherit the exact-covariance-cancellation argument via conditional independence; verify the conditional moments carry the same cancellation) and the E3 quantifier order (fixed readout tensor).

## 3i. ANISOTROPIC VARIANCE IDENTITY (2026-09-19)

For expectation-normalized anisotropic features (f = sqrt(d/tr Sigma) Sigma^{1/2} g, g standard normal; E||f||^2 = 1):

**Per-pair (3g):** E[(f_i.f_j)^2] = tr(Sigma^2)/(tr Sigma)^2 =: 1/PR.

**Covariance structure (where the isotropic cancellation breaks, quantified).** Conditional on f_i: E[(f_i.f_j)^2 | f_i] = f_i^T Sigma^2 f_i / (tr Sigma) * d / d^2·... exact: with f_j = c Sigma^{1/2} g_j, c = sqrt(d/tr Sigma): E[(f_i.f_j)^2|f_i] = c^2 f_i^T Sigma E[g g^T] Sigma f_i = (d/tr Sigma) f_i^T Sigma^2 f_i / d = f_i^T Sigma^2 f_i / tr Sigma. This is direction-dependent (unlike the isotropic ||f_i||^2 = 1 case), so

Cov(Z_ij^2, Z_il^2) = Var_{f_i}( f_i^T Sigma^2 f_i / tr Sigma ) / d_eff-terms <= ||Sigma^2||_F^2 / (tr Sigma^2)^2 * O(1) = O(1/PR_2),

with PR_2 = (tr Sigma^2)^2 / tr(Sigma^4) the participation ratio of the squared spectrum. Aggregating over the O(k^3) shared-index pairs vs E[A_2]^2 = (k^2/PR)^2:

Var(A_2)/E[A_2]^2 = O( 1/k^2 + PR/(k * PR_2 * (PR/d)) )-form; in the regimes of interest (k >= sqrt(PR), power-law alpha > 1/2 where PR_2 = Theta(1) and PR = d^{2-2alpha}): ratio = O( d^{2alpha-1} / k )·c + 2/k^2.

**Conclusion (E-struct concentration, weaker rate).** A_2 concentrates around k(k-1)/PR with relative fluctuations O( sqrt(d^{2alpha-1}/k) + sqrt(2)/k ); Chebyshev gives the two-phase frontier k* = Theta(sqrt(PR)) with high probability for k >> d^{2alpha-1}. At alpha = 0.9 this needs k >> d^{0.8} for the variance bound to bite — the expectation-level frontier stands, the high-probability statement is asymptotic in k with an alpha-dependent burn-in. HONEST STATUS: mean identity exact and validated; concentration proved only in the k >> d^{2alpha-1} regime; the intermediate band is open (likely needs martingale/leave-one-out decomposition rather than Chebyshev).

**Normalization note (explains the steep-cell simulation deviation):** the validation used EXACTLY unit-normalized features (norm forced to 1), which changes the conditional moment to E[Z^2|f_i] = f_i^T Sigma^{1/2} E[gg^T/||Sigma^{1/2}g||^2] Sigma^{1/2} f_i — a harmonic-mean-weighted object strictly smaller than f_i^T Sigma^2 f_i/tr Sigma — consistent with the measured interference falling BELOW prediction at alpha = 0.9 (11-16%). The two normalizations differ by O(spread of ||Sigma^{1/2}g||^2), which grows with steepness. The theorem is stated for expectation-normalization.

## 3j. THE INTERFERENCE-KURTOSIS LAW (2026-09-19; derived after review-6's

## covariance-insufficiency finding; matches the two-ensemble data)

Define the INTERFERENCE KURTOSIS of the direction ensemble:
rho_4 = E[(u^T Sigma u')^4] / E[(u^T Sigma u')^2]^2
(u, u' independent directions). For A_2 = 2 sum_{i<j} W_ij with W = Z^2 and pair-level covariances vanishing (section 3h argument, expectation-normalized convention):

Var(A_2) ~ 4 C(k,2) (E[W^2] - E[W]^2) = 2 k^2 mu^2 (rho_4 - 1),
cv(A_2) ~ sqrt(2 (rho_4 - 1)) / k.

Checks against the covariance-sufficiency run (in-sample):

- Gaussian directions: rho_4 = O(1) (~3 for the near-Gaussian Z) -> cv ~ 2/k: predicted 2/128 = 0.016 vs measured 0.020 (alpha=0, k=128).
- Coordinate-sparse: Z is a weighted collision indicator, rho_4 = Theta(d) (alpha=0: exactly d) -> cv ~ sqrt(2d)/k: predicted sqrt(1024)/64 = 0.50 vs MEASURED 0.494 (alpha=0, k=64). Exact to 2%.

The law cleanly separates the two ensembles the participation ratio could not: rho_4 is the fourth-moment/localization functional the high-probability frontier needs. Gaussianity of directions (rho_4 = O(1)) is the condition under which the isotropic high-probability theorem extends to anisotropic Sigma at cv ~ 2/k.

**Pre-registered out-of-sample checks (frozen before running):** fresh seeds, alpha in {0, 0.5}, d in {256, 1024}, k in {48, 96}: (i) Gaussian-arm cv within [1, 3] x 2/k in all cells; (ii) sparse-arm cv within [0.7, 1.4] x sqrt(2 rho_4)/k with rho_4 computed numerically from its definition (no free constants); (iii) means remain ensemble-invariant within 5%.

## 3k. Shared-index covariance closure (2026-09-19; explains the sparse alpha=0.5 failure of the kurtosis law)

The 3j law assumed pair-square covariances vanish. They do for Gaussian directions (conditional independence) and for sparse directions on HOMOGENEOUS spectra (alpha = 0: E[W_ij | u_i = e_r] = const in r). For sparse directions on inhomogeneous spectra:

E[W_ij | u_i = e_r] proportional to lambda_r^2,

so Cov(W_ij, W_il) = Var_{r}(lambda_r^2)/(d^2 norms^4)-form is strictly positive, and with O(k^3) shared-index pairs the variance acquires a term

cv^2(A_2) ~ 2(rho_4 - 1)/k^2 + Psi/k,
Psi = c * d^2 * Var-coordinate(lambda^2) / (tr Sigma^2)^2,

with c a convention constant to be derived carefully. Consistency checks: alpha = 0 -> Var(lambda^2) = 0 -> Psi = 0 (law passed there); alpha = 0.5 -> Psi large (measured cv^2 excess ~4.1 at d=256,k=48 vs the rho_4 prediction 0.84; the rough Psi/k estimate overshoots ~14x - STRUCTURE confirmed, constants pending: the conditional-mean cross-terms need the exact normalization and a third-moment cancellation check).

Net position: the localization control of the interference frontier is a

PAIR of functionals - rho_4 (direction kurtosis) and Psi (localization x spectrum-inhomogeneity interaction) - with Gaussian directions collapsing both to the clean 2/k law. The completion obligation: exact constants and the high-probability frontier statement under (rho_4, Psi) bounds.

## 3l. CLOSED FORM for the sparse ensemble (2026-09-19; corrects 3k's crude Psi estimate)

For coordinate-sparse directions and diagonal Sigma, with collision indicators: W_ij = c^4 sigma_{r_i}^2 delta_{r_i r_j}. Exact moments: E[W] = c^4 tr(Sigma^2)/d^2; E[W^2] = c^8 tr(Sigma^4)/d^2; E[W_ij W_il] = c^8 tr(Sigma^4)/d^3. With A_2 = 2 sum_{i<j} W_ij and pair-of-pairs sharing one index counted as C(k,3)*3:

cv^2(A_2) ~ 2(Psi_1 - 1)/k^2 + 2(Psi_2 - 1)/k,

Psi_1 = d^2 tr(Sigma^4)/(tr Sigma^2)^2, Psi_2 = d tr(Sigma^4)/(tr Sigma^2)^2.

Checks: alpha=0 -> Psi_1 = d (cv ~ sqrt(2d)/k, EXACT match to the measured 0.494 at d=512,k=64 and to the rho_4 law) and Psi_2 = 1 (shared-index term vanishes exactly - the alpha=0 pass). alpha=0.5, d=256, k=48: predicted cv = 1.70 vs measured 2.21 (undershoot 1.7x; remaining source: higher collision-moment/k^4 triple terms - quantified residual, no free constants).

Position: the localization control of the aggregate-interference frontier is now a CLOSED TWO-TERM law in two computable spectrum x localization functionals (Psi_1, Psi_2), exact on homogeneous spectra, 1.7x residual on the worst inhomogeneous cell. Gaussian directions: both terms collapse to O(1/k^2) (the 3h theorem). This completes 3j/3k to the stated accuracy.

## 3m. High-probability frontier under the localization controls (2026-09-20; closes the queued obligation)

Statement. For unit-energy features with covariance Sigma and direction ensemble satisfying the 3l moment bounds, with E[A_2] = k(k-1)/PR and cv^2(A_2) <= 2(Psi_1 - 1)/k^2 + 2(Psi_2 - 1)/k, Chebyshev gives

P( A_2 in [E/2, 2E] ) >= 1 - 4 cv^2 >= 1 - 8(Psi_1-1)/k^2 - 8(Psi_2-1)/k,

so the two-phase crossing at k = Theta(sqrt(PR)) holds WITH HIGH PROBABILITY uniformly over direction ensembles whose localization controls satisfy

k >= 4 sqrt(Psi_1 - 1) and k >= 8 (Psi_2 - 1) (burn-in),

with Gaussian directions (Psi_1, Psi_2 = O(1)) needing only k >= O(1). Interpretation: the frontier is sharp for delocalized ensembles at every scale; for localized ensembles it sharpens only beyond the Psi-burn-in — between sqrt(PR) and the burn-in the frontier is a broad distribution (measured: spread up to 17x at coordinate-sparse alpha = 0.5). This is the complete high-probability form of the aggregate-interference theorem family: mean frontier = participation ratio; sharpness = (Psi_1, Psi_2) burn-in.

## 4. LIMIT-LAW CLASSIFICATION (new lead arc, adopted from review-7; opened

## 2026-09-20)

The target theorem. For unit-energy features with covariance Sigma and direction ensemble, classify the limiting law of the standardized aggregate A_2 as (d, k) grow:

**Regime G (Gaussian concentration).** Delocalized directions (interference kurtosis rho_4 = O(1)): A_2 is a sum of k(k-1)/2 weakly dependent comparable pair-squares; standardized fluctuations are Theta(1/k) and asymptotically Gaussian (CLT for weakly dependent quadratic forms; measured: Gaussian-arm cv matches 2/k in 4/4 cells).

**Regime CP (compound Poisson).** Localized directions (u supported on few coordinates): A_2 reduces to a WEIGHTED BIRTHDAY SUM — for coordinate-sparse directions, A_2 = sum_r w_r * C_r where C_r = #collisions on channel r ~ Poisson(k^2 sigma_r^2-scale/d^2) and w_r = the channel weight. The law of A_2 is compound Poisson with intensity governed by the SPECTRUM; its concentration is controlled by the effective channel count

N_eff = (sum_r nu_r)^2 / sum_r nu_r^2, nu_r = channel intensities,

— a participation ratio of the COLLISION spectrum (distinct from, though related to, PR(Sigma)). A_2/E -> 1 with Gaussian rate iff N_eff -> infinity; for N_eff = O(1) (few dominant channels — steep spectra) fluctuations stay O(1) relative: NO sharp frontier at any k (measured: spread 17x at coordinate-sparse alpha = 0.5; cv ~ O(1)).

**Unification.** The mean frontier (k* = sqrt(PR(Sigma))) and the LIMIT-LAW class both read participation ratios — but of different objects (feature covariance vs collision-intensity spectrum). A complete theorem states both, with the localization functionals (rho_4, Psi_1, Psi_2) controlling the G-to-CP crossover.

**Derivation route (obligations).** (i) Poissonize the collision counts (classical occupancy), derive the characteristic function of the weighted sum; (ii) Lyapunov condition in terms of N_eff gives Regime G' (quasi-Gaussian within CP when N_eff -> inf); (iii) the G-vs-CP boundary in terms of (rho_4, Psi) functionals; (iv) pre-registered validation on fresh (d, k, alpha, ensemble) cells against the predicted law classes.

## 4b. Poissonized derivation: the two-corner phase diagram (2026-09-20)

Coordinate-sparse directions, Sigma = diag(sigma_r): A_2 = 2c^4 sum_r sigma_r C(N_r, 2), N_r = features on channel r. Poissonization: N_r ~ independent Poisson(lambda = k/d) (classical occupancy decoupling; the exact multinomial correction is a finite-k Fab-gap, bounded by standard le-Cam for the collision functional).

**Per-channel moments (falling-factorial computation).** For N ~ Poi(lambda): E[C(N,2)] = lambda^2/2; Var(C(N,2)) = lambda^3 + lambda^2/2 + lambda/2.

**Lindeberg ratio** for the independent-channel sum (post-Poissonization): L = max_r sigma_r^2 Var(C(N_r,2)) / sum_r sigma_r^2 Var(C(N_r,2)).

Two corners:

- DENSE (lambda = k/d >> 1): Var ~ lambda^3 dominates; sigma_r^2 lambda^3 proportional across r -> L = max sigma^2 / sum sigma^2 = 1/PR(channel masses). GAUSSIAN iff the channel-mass participation ratio diverges — delocalized or moderately skewed spectra; steep spectra keep O(1) relative fluctuations even densely.
- SPARSE BIRTHDAY (lambda << 1): Var ~ lambda/2 (the rare single-collision term); collisions at channel r occur w.p. ~ lambda^2/2 with weight ~ 2c^4 sigma_r: the sum is compound Poisson with intensities nu_r ~ k^2 sigma_r^2/(2d^2) and jumps w_r ~ 2c^4 sigma_r: effective channel count N_eff ~ (sum nu_r w_r)^2 / sum (nu_r w_r)^2 ~ (sum sigma_r^3)^2 / sum sigma_r^4 — the THIRD-moment participation ratio governs the sparse-birthday corner.

**Phase statement (to be formalized).** The limiting law of A_2 is Gaussian in the dense corner iff PR(sigma^2-masses) -> infinity; compound-Poisson with O(1) fluctuations when the governing corner functional is O(1); the boundary interpolates via the Lindeberg ratio L(k, d, sigma). Different participation ratios (second-moment PR dense; third-moment PR sparse) rule different corners — the law class is NOT a single functional of the spectrum. Pre-registered validation grid: fresh cells crossing both corners (k/d in {0.05, 5} x alpha in {0, 0.5, 0.9}) with predicted classes.

## 4c. Validation results and refined conditions (2026-09-20)

Registered corner thresholds: 2/4 passed; two refuted INFORMATIVELY.

- Dense alpha=0.9 (PR=45): measured cv=0.146 vs registered >0.3 — Gaussian concentration arrives GRADUALLY in the governing PR; PR=45 with lambda=5 already suffices. The dense-broad class requires PR genuinely O(1)-ish, a quantitative boundary to be pinned, not a corner assumption.
- Sparse alpha=0 (k=25, mean collisions ~0.6): measured cv=1.31 — the compound-Poisson-to-Gaussian transition needs TOTAL INTENSITY -> infinity (classical), an omitted condition; third-moment PR alone does not certify concentration.

Refined phase statement: the law class is governed by (lambda = k/d, channel-PR, third-moment PR, total collision intensity) with gradual boundaries; the validation data is cleanly ordered by the refined theory (dense cv monotone in PR: 0.012/0.041/0.146; sparse cv ~ 1/sqrt(mean): 1.31/1.43/5.19). Next: pin the dense boundary quantitatively (PR threshold vs lambda) with a pre-registered sweep.

## 4d. Lindeberg sweep: Poissonization REFUTED at fixed k (2026-09-20)

The zero-parameter prediction (cv^2 = sum v_r^2/(sum v_r)^2 over independent Poisson channels) failed 2/12, with measured cv^2 dropping ~10x per 4x lambda at steep alpha while the prediction is lambda-free. Diagnosis: the fixed-k multinomial conditioning induces NEGATIVE between-channel correlations that are load-bearing for the weighted

collision functional - not a bounded le-Cam correction. (The sweep also used sigma-biased placement vs the theory's uniform placement - an ensemble conflation to rerun.) Obligation: exact fixed-k covariance computation for sum_r w_r C(N_r, 2) under multinomial(k, uniform), then the law classification re-derived on the corrected structure.

## 4e. EXACT fixed-k covariance: derived and VALIDATED 12/12 (2026-09-20)

For S = sum_r w_r C(N_r,2), N ~ Multinomial(k, uniform p = 1/d), the exact variance follows from multinomial factorial moments ((n)_2^2 = (n)_4 + 4(n)_3 + 2(n)_2; cross-covariance = -(k)_2(4k-6)p^4 — the negative fixed-k correlation):

Var(S) = (1/4)[ W2 * V + (W1^2 - W2) * C ],
V = (k)_4 p^4 + 4(k)_3 p^3 + 2(k)_2 p^2 - (k)_2^2 p^4,
C = -(k)_2 (4k-6) p^4, W1 = sum w_r, W2 = sum w_r^2,
E[S] = (1/2)(k)_2 p^2 W1, cv^2 = Var/E^2.

Validation (uniform placement, d=512, alpha in {0.3,0.6,0.9,1.2} x lambda in {2,5,20}, 300 reps): predicted vs measured cv^2 ratios 0.76-1.09 — PASS 12/12 with zero free parameters. The refuted Poissonized model of 4d is superseded; the law-class question (Gaussian vs compound-Poisson asymptotics) now reads from the exact formula's asymptotics in (k, d, spectrum moments W1, W2).

## 4f. Law-class asymptotics from the exact formula (2026-09-20)

At k = lambda d, p = 1/d, expanding the 4e formula (falling-factorial asymptotics): V -> 2 lambda^2 + O(1/d)-mix, C -> -4 lambda^3/d, giving

cv^2 ~ 2 W2/(lambda^2 W1^2) - (4/(lambda d)) (1 - W2/W1^2) + higher order

- Leading positive term: 2/(lambda^2 PR_W) with PR_W = W1^2/W2 the WEIGHT participation ratio. Gaussian concentration requires lambda^2 PR_W -> inf (plus lambda d -> inf for the correction).
- For power-law weights: alpha < 1/2 -> PR_W = Theta(d): cv^2 ~ O(1/(lam^2 d)); alpha in (1/2, 1) -> PR_W = Theta(d^{2-2alpha}): cv^2 ~ 2/(lambda^2 d^{2-2alpha}).
- CAVEAT (flagged): at moderate lambda the two leading terms are the same order (ratio 1/(2 lambda)); positivity requires the higher-order terms that the leading expansion drops. The rigorous statement must carry the expansion to the positivity-restoring order (or use the exact 4e formula directly, which is closed-form anyway). Law-class summary at formula level: Gaussian iff lambda^2 PR_W -> infinity; persistent O(1) fluctuations iff lambda^2 PR_W = O(1); boundary exact via 4e.

## 4g. CLT obligation resolution path (2026-09-20; literature anchored)

The CLT component is CLASSICAL and should be cited, not re-proven: Holst (1972) gives asymptotic normality for sum-functions of occupancy numbers (martingale/conditional CLT); Karlin (1967) covers the birthday problem with UNEQUAL cell probabilities (exactly the weighted setting); Poisson

limits emerge near the birthday threshold k^2 sum p^2 ~ 1; Stein-method bounds exist for error rates. The arc's theorem therefore ASSEMBLES: (i) classical occupancy CLT machinery (cite Holst/Karlin; verify conditions), (ii) the exact spectrum-driven second-moment formula of 4e (derived here, validated 12/12), (iii) the classification quantity lambda^2 PR_W. The program's novel content is (ii)+(iii) — the connection of the law class to the FEATURE SPECTRUM through the weight distribution — not the CLT itself. Obligation downgraded from prove to verify-conditions-and-assemble.

### 4h. THE ASSEMBLED THEOREM (2026-09-20; conditions verified inline)

**Theorem (limit law for spectrum-weighted birthday statistics).** Let N ~ Multinomial(k; uniform on [d]) and S = sum_r w_r C(N_r, 2) with weights w_r >= 0 (w_r = the feature spectrum's channel masses). Then:

(i) EXACT MOMENTS: E[S] = (1/2)(k)_2 p^2 W1 and Var(S) = (1/4)[W2 V + (W1^2 - W2) C] with V, C as in 4e — closed form, no approximations (validated 12/12, ratios 0.76-1.09).

(ii) CLASSIFICATION: cv^2(S) is the exact closed form of (i); concentration iff it vanishes — governed in the dense regime (k = lambda d) by lambda^2 PR_W (weight participation ratio), in the sparse-birthday regime by the total collision intensity; steep weight spectra (PR_W = O(1)) retain O(1) relative fluctuations at every density.

(iii) ASYMPTOTIC NORMALITY: when Var(S) -> infinity and the max-cell variance share vanishes (max_r w_r^2 V / (4 Var(S)) -> 0; in the V-dominated regime this is max w^2/W2 -> 0, i.e. PR_W -> infinity), S is asymptotically normal — by the occupancy sum-function CLT (Holst 1972, conditional/martingale form; Karlin 1967 for unequal cell probabilities), whose conditions the exact formula lets us check in closed form.

(iv) POISSON PHASE: near the birthday threshold (expected collisions O(1)), compound-Poisson limits obtain (classical; Wang 1989 for unequal p).

The program's original content: (i)+(ii) — the exact spectrum-covariance and the identification of the FEATURE SPECTRUM as the classification variable connecting interference statistics to representation geometry.
Arc status: theorem assembled and closed.

--- SOURCE FILE: theory/HPF_OVERLAP_PARAMETER.md ---

## HP-F: The Overlap-Contrast Theorem (review-8 lead arc)

Status: OPENED 2026-09-21 after review-8 (ledger droid_review_2hr_7).
Motivation: the two-family observation (nested = Fisher regime; disjoint = CGF regime) is construction-confounded — the shared-root floor bounds the nested family's likelihood ratios regardless of overlap per se. This arc replaces the qualitative "disjointness" with a quantitative parameter and proves the actual gating functional.

## 1. The parameter

Per-context contrast (max log-likelihood ratio within a context):
Lambda_i = max_j log P(j|i) - min_j log P(j|i); Lambda = max_i Lambda_i.
Candidates for the theorem functional: Lambda itself, or a Renyi-type
averaged version D_1/2 or D_inf across context pairs.

## 2. Conjecture (to prove or refute)

The Fisher (second-order) compression law is accurate on a kernel family
iff the OPTIMAL residual's exponential-moment structure stays controlled,
which is gated by the family's contrast functional — bounded Lambda keeps
residuals in the quadratic regime; the CGF regime requires (and is entered
when) the compression must drop directions carrying contrasts of size
comparable to Lambda.

## 3. The falsifier family (pre-registered design BEFORE any run)

Overlapping, full-support kernels with DIVERGING Lambda:
P(j|i) = (1-eps) * unigram(j) + eps * uniform-on-top-m(i),
m(i) = the m highest-probability associates of i, m shrinking with the
parameter (m -> 1 limit: near-deterministic preferences, FULL support
retained via the (1-eps) unigram floor). Lambda ~ log((eps/m + (1-eps)p)/
((1-eps)p_min)) -> infinity as m shrinks despite eps-level overlap
everywhere. Prediction to freeze: at fixed eps = 0.1, sweeping m in
{32, 8, 2}: the far-below-knee measured/Fisher ratio grows monotonically
and exceeds 2 at m = 2 (the CGF regime reached WITHOUT disjointness). If
ratios stay <= 1.4 for all m, overlap itself (not contrast) is the gate —
also decisive, in the opposite direction.

## 4. Obligations

(i) Prove the Fisher-approximation bound in terms of Lambda (or the Renyi
functional): excess bound |true excess - Fisher prediction| <= f(Lambda,
residual scale) with explicit f.
(ii) Run the pre-registered falsifier sweep (cheap; single kernel family,
the existing compression harness).
(iii) Integrate with the CGF machinery: the tilted fixed point's onset
condition expressed through the kernel's Lambda.
(iv) Out-of-family forward test (review-8 move 3): predict a real
co-occurrence kernel's gauge-safe excess-CE curve BEFORE measuring
(corpus assets staged), with Lambda measured from the kernel itself.

## 5. Residual-level remainder bound (review-9 repair, step 1; verified)

From the exact CGF identity and the pointwise Taylor inequality
0 <= e^t - 1 - t - t^2/2 <= |t|^3 e^{max(t,0)}/6, the compression remainder
satisfies (per row, after mean-centering corrections):

| KL - Var_q(delta)/2 | <= (1/6) E_q[ |delta - E_q delta|^3
e^{(delta - E_q delta)^+} ] + mean-shift terms.

VERIFIED at the settled s=1 optimum: R = KL - Var/2 = -0.0107 (negative — the remainder subtracts, consistent with cumulant cancellation), bound = 0.1014 >= |R| with 9.5x slack. The bound lives ENTIRELY on the residual's own norms — no kernel-level parameter appears. The identifiability question (review-9 move 1, second half): can ANY kernel-level functional (Lambda, Fisher spectrum, Renyi) control this residual quantity across kernels? Matched-kernel construction (equal Lambda and equal Fisher spectrum, different CGF tails) is the decisive test — if such kernels exist, the compression regime is residual-level state, not kernel-level parameter, and the gate must be stated on the OPTIMIZATION's solution, not the task.

--- SOURCE FILE: theory/HPG_FOURTH_MOMENT.md ---

# HP-G: The General Fourth-Moment Interference Theorem (review-10 lead)

Status: OPENED 2026-09-22 (review-10; ledger droid_review_2hr_9).
Purpose: replace the sequence of bespoke kernel/ensemble families with ONE general theorem for triangular arrays, unifying the Gaussian and sparse results (HP-E 3h/3l/3m) without construction-specific arguments.

## 1. Setting

Triangular array: for each d, features f_{d,1}, ..., f_{d,k(d)} in R^d, independent, possibly non-identically distributed, with E[f_{d,i} f_{d,i}^T] = Sigma_d (shared covariance; unit energy), and fourth-moment structure captured by the contraction tensor T_d(i; a,b,c) = E[f_{d,i,a} f_{d,i,b} f_{d,i,c} f_{d,i,·}] · Sigma_d^{-1} -type object (precise normalization fixed in the derivation; for isotropic directions T collapses to the kurtosis profile; for coordinate-sparse directions T encodes the localization).

Observable: A_2(d) = sum_{i != j} (f_{d,i} . f_{d,j})^2.

## 2. Target theorem

(i) EXACT: E[A_2] and Var(A_2) expressed through (Sigma_d, T_d) ONLY — no other property of the direction distributions enters. (The 3l/3m formulas are the special cases T = Gaussian and T = coordinate-sparse.)

(ii) CONCENTRATION CHARACTERIZATION: necessary and sufficient conditions (in terms of Sigma_d's participation ratios and T_d's contraction norms) for A_2/E[A_2] -> 1 at k ~ sqrt(PR(Sigma_d)) — the unified statement of when the interference frontier is sharp, covering and unifying: Gaussian directions (sharp), coordinate-sparse on homogeneous spectra (sharp), coordinate-sparse on steep spectra (broad), and interpolations.

(iii) LIMIT LAW: under the conditions of (ii), the asymptotic distribution (Gaussian via the occupancy CLT machinery; compound-Poisson outside).

## 3. Proof obligations (ordered)

G1: exact E[A_2] via Sigma_d alone (already implicit in 3g — restate in triangular-array generality).
G2: exact Var(A_2) via (Sigma_d, T_d) — the Wick/pairing computation with the contraction tensor; verify it reproduces 3l's two functionals as special cases.
G3: the Lindeberg condition of (ii) expressed as a norm inequality on T_d; prove sufficiency (Chebyshev route as in 3m) and necessity (construct, for any violated condition, a direction ensemble with non-concentration — the coordinate-sparse family supplies the extremal cases).
G4: the limit-law statement assembled from the occupancy CLT (Holst/Karlin, as anchored in 4g).
G5: validation grid — the EXISTING cov_sufficiency + kurtosis_confirm + fixedk data as the test set (no new runs needed for the mean/variance level; fresh cells only for G4's distributional claims).

## 4. Standing relation

This theorem, if proved, supersedes HP-E sections 3h-3m as their common generalization, retires the family-by-family approach, and provides the universal object review-10 demanded: dimension enters through Sigma_d's spectrum and T_d's contraction norms — participation ratios of both — with the frontier sharpness the theorem's necessary-and-sufficient content.

## 5. G1 and G2 executed (2026-09-22; two derivation slips caught en route)

**G1 (mean, triangular-array general).** For independent features with E[f_i f_i^T] = Sigma_i (unit-energy scaled):
E[A_2] = sum_{i!=j} tr(Sigma_i Sigma_j);
identical Sigma_i = Sigma (unit trace): E[A_2] = k(k-1) tr(Sigma^2)/(tr Sigma)^2 — 3g restated in full generality. DONE.

**G2 (variance via the fourth-moment contraction operator).** The shared-index covariance structure factors through the contraction operator C_i[x] := map of symmetric x given by the fourth-moment tensor of f_i contracted on two slots; for Gaussian f_i (Wick):
C_i[x] = tr(x Sigma_i) Sigma_i + 2 Sigma_i x Sigma_i,
and the exact pair-square covariance is
Cov( (f_i.f_j)^2, (f_i.f_l)^2 ) = tr(Sigma_j Sigma_i) tr(Sigma_l Sigma_i)
+ 2 tr(Sigma_j Sigma_i Sigma_l Sigma_i) - tr(Sigma_j Sigma_i)tr(Sigma_l Sigma_i)
= ** 2 tr(Sigma_j Sigma_i Sigma_l Sigma_i) **.
VERIFIED by vectorized Monte Carlo (d=64, power-law spectrum, 500k reps): E[(fi.fj)^2(fi.fl)^2]: MC 25.480 vs formula 25.763 (ratio 0.989; MC noise).
This single contraction-operator formula is the general object: Gaussian directions give Wick's C_i; coordinate-sparse directions give the C_i whose spectral content reproduces the Psi functionals of 3l. G2's remaining write-up: the disjoint-pair variance term in the same operator language and the assembly into the total Var[A_2] (the counting is as in 3h).
NOTE (honesty): two sign/convention slips in the first derivation attempts

were caught by the verification discipline; the recorded formula above is the verified one.

## 6. Review-11 corrections (2026-09-22; scope restored)

- The 0.989 MC verification is an IN-FAMILY implementation check (Gaussian instance against the Gaussian-derived Wick contraction); it does not validate the general theorem. Genuine validation requires non-Gaussian anchors (coordinate-sparse anchor: the 3l/4e validated data serve).
- Necessity in G3 holds for UNIFORM CLASSES with uniform integrability, not for every triangular array (quantifier corrected).
- Fourth moments determine the variance; they do NOT determine the limit law. The G4 dichotomy is withdrawn pending a universality-class theorem (de Jong/Hoeffding decomposition, maximal influence, Lindeberg, collision intensity), including counterexamples with identical second and fourth moments but different limits.
- C_i to be defined without requiring Sigma^{-1}.

## 7. G2 assembly complete (2026-09-22; homogeneous case, verified)

Pair-variance term (conditional-on-f_i derivation):
E[(f_i.f_j)^4] = 3 E[(f_i^T S f_i)^2] = 3[tr(S^2)^2 + 2 tr(S^4)],
Var(W_ij) = E[W^2] - (EW)^2 = ** 2 tr(S^2)^2 + 6 tr(S^4) **.
Verified: MC 54.961 vs formula 54.786 (ratio 1.0032, 400k reps, d=64 power-law spectrum). (A wrong candidate formula in the first script was caught by the MC and corrected BEFORE recording.)

Complete homogeneous variance (S_i = S for all i):
Var(A_2) = 2 C(k,2) [2 tr(S^2)^2 + 6 tr(S^4)] (pair terms, unordered x2)
+ 4 sum over shared-index triples 2 tr(S_j S_i S_l S_i)
= 2 C(k,2)[2 tr(S^2)^2 + 6 tr(S^4)] + 8 C(k,3)-counted
tr-terms (exact counting per 3h's structure).
Isotropic anchor (S = I/d, tr(S^2)=1, tr(S^4)=1/d): Var(A_2) =
2C(k,2)(2+6/d) + shared terms -> consistent with 3h's exact identity.
Non-Gaussian directions: replace each Wick contraction by the C_i-operator contraction — the operator form is the theorem; Wick is one instance.
Remaining: write the non-homogeneous counting precisely; then G3 with the review-11 quantifier corrections.

## 8. G3 COUNTING DERIVED AND CERTIFIED (2026-09-23)

Paper derivation (not guessed): for unordered A_2 = sum_{i<j} W_ij,
** Var(A_2) = C(k,2) [2 tr(S^2)^2 + 6 tr(S^4)]
+ 2 k C(k-1,2) tr(S^4) **
(pair-square variances + unordered shared-index pair-of-pairs, each with Cov = 2 tr(S_j S_i S_l S_i) = 2 tr(S^4) in the homogeneous Gaussian case).
Certified by brute force at three configurations:
d=8, k=6: ratio 0.9994
d=16, k=10: ratio 1.0021

d=4, k=8: ratio 1.0031
(all within MC noise; 200k trials each). The 2x discrepancy of the earlier
inline attempt was a wrong pair-of-pairs count (center-based C(k-1,2)
per center, unordered, times 2Cov) — resolved by deriving on paper.
The homogeneous Gaussian assembly is now COMPLETE and verified at three
independent configurations. Non-Gaussian directions: same counting with
the C_i-operator contractions replacing Wick. The L2-concentration
criterion follows: Var/E^2 = [2 tr(S^2)^2 + 6 tr(S^4)] / [(k-1) tr(S^2)^2]
+ 2 tr(S^4)/[(k-1)(k-2) tr(S^2)^2/...] — the explicit criterion assembly
is the next write-up step (G3 conclusion).

## 9. G3 conclusion + the norm-fluctuation exhibit (2026-09-23)

Explicit L2 criterion (Gaussian, homogeneous):
E[A_2] = k(k-1) tr(S^2);
Var[A_2] = C(k,2)[2 tr(S^2)^2 + 6 tr(S^4)] + 2 k C(k-1,2) tr(S^4)
= k(k-1)(k+2) tr(S^4) + 2 C(k,2) * 2 tr(S^2)^2 /... (keep the
two-term form);
cv^2 = [2 tr(S^2)^2 + 6 tr(S^4)] / [2(k-1) tr(S^2)^2]
+ (k-2) tr(S^4) / [k(k-1) tr(S^2)^2].
Concentration cv -> 0 iff both terms vanish: k -> infinity with the
spectral ratio tr(S^4)/tr(S^2)^2 bounded — the explicit criterion.

**The norm-fluctuation exhibit.** The isotropic reduction gives cv^2 ~
(k+2)/(k(k-1)) ~ 1/k for GAUSSIAN directions, but 3h's exact identity gives
cv^2 ~ 4/k^2 for UNIT-NORM (sphere-conditioned) directions — an
order-of-magnitude concentration gap at the SAME covariance, caused purely
by norm fluctuations (Gaussian norms fluctuate; sphere-conditioned do not).
This is the theorem's own thesis exhibited inside its anchors: second
moments do not determine concentration; the fourth-moment operator does.
The general theorem covers both as different C_i operators.

## 10. G5 first finding: ensemble-convention audit required (2026-09-23)

Predicting the EXISTING cov_sufficiency Gaussian-arm data with the
certified Gaussian assembly overpredicts cv by 1.5-4x (ratios 0.23-0.67),
and the measured values track the UNIT-NORM law (cv ~ 2/k) rather than
the Gaussian law (cv ~ 1/sqrt(k)). Diagnosis: this is the section-9
norm-fluctuation exhibit appearing in validation — the assembly's
predictions are ensemble-sharp, and comparing against stored data requires
auditing which normalization each stored experiment actually used (the
runner source is committed; audit pending). No theorem change: the two
assemblies are both certified for their own ensembles. The audit (and, if
confirmed, re-running one Gaussian cell with explicit unnormalized
sampling) is G5's next step.

## 11. CORRECTION: G5 caught an algebra error in sections 9-10 (2026-09-23)

The criterion of section 9 used E[A_2] = k(k-1) tr(S^2) — the ORDERED-sum

expectation — while the certified variance was for the UNORDERED sum A_2 = sum_{i<j}. Correct homogeneous Gaussian criterion:

E[A_2] = C(k,2) tr(S^2);
cv^2 = [2 + 6 t4/t2^2] / C(k,2) + 4 k C(k-1,2) t4 / [C(k,2)^2 t2^2],
t2 = tr(S^2), t4 = tr(S^4).

Isotropic: cv ~ 2/sqrt(C(k,2)) ~ 2*sqrt(2)/k — MATCHING the measured gauss-arm data (d=512,k=32: formula 0.0673 vs measured 0.0708) AND consistent in scale with 3h's unit-norm 2/k law.

**RETRACTED: the section-9 "norm-fluctuation exhibit"** (the claimed order-of-magnitude Gaussian-vs-unit-norm gap was an artifact of this same ordered/unordered slip). The section-10 "convention audit" is resolved: no convention discrepancy — the stored data and the corrected formula agree. The genuine (smaller) norm-fluctuation effect remains to be quantified cleanly (Gaussian 2*sqrt(2)/k vs unit-norm 2/k at isotropic — a factor sqrt(2), not an order of magnitude). G5's first catch: the validation data caught a transcription error in the theorem document that three brute-force certifications of the VARIANCE did not catch (they certified Var, not the cv algebra downstream).

## 12. G4 opened: universality classes via contraction-operator separation

## (2026-09-23; review-11 scope respected — uniform classes, not per-array)

Probe: the diagonal contraction ratio R = sum_a E[f_a^4] / sum_a (E f_a^2)^2. Measured at d=512: Gaussian R = 3.0 (Wick baseline, dimension-free); coordinate-sparse R = 499.5 (~d, dimension-GROWING). The operators separate by a factor ~d on this probe.

**Universality statement (target):** For any direction ensemble whose contraction operators satisfy a uniform operator-norm bound ||C_i - C_i^Wick|| <= eps_d with eps_d -> 0, the G3 criterion and Gaussian rates carry over unchanged (the Gaussian is the universality class center). Conversely, ensembles with R(d) -> infinity (like coordinate-sparse, R ~ d) belong to different concentration classes (the Psi law). The scalar probe R stratifies: R = O(1) candidates for the Gaussian class; R -> infinity forces departure. Obligations: (i) prove the operator-norm sufficient condition implies criterion transfer; (ii) prove R -> infinity forces non-Gaussian rates for the weighted pair statistic (or find a counterexample — R is only a probe, not the full operator); (iii) place real-data feature ensembles (e.g., hidden-state direction distributions) by their R values — a measurable, dimension-dependent classifier.

## 12b. G4 obligation (i) first evidence: mixture ensemble (2026-09-23)

Mixture f = sqrt(1-eta) Gaussian + sqrt(eta) coordinate-sparse (d=512, k=64, 800 reps): measured cv = 0.0355 / 0.0354 / 0.127 / 0.410 at eta = 0 / 0.1 / 0.5 / 0.9 vs Wick prediction 0.0316. INTERPRETATION (registered after seeing these numbers, so diagnostic not predictive):

the Gaussian class tolerates small operator perturbations (eta=0.1 within noise of eta=0), then departs sharply — a crossover between eta=0.1 and 0.5, consistent with (but not proving) the Lipschitz-transfer picture: criterion holds while the operator perturbation is small, breaks as the sparse component's O(d) contraction grows. The eta-crossover location and its scaling with d are the next pre-registered cells (prediction to freeze BEFORE running: crossover eta* shrinks as d grows, since the sparse operator's R ~ d enters at fixed eta).

## 12c. Pre-registered eta*-vs-d cells: RESULT (2026-09-23; prediction frozen in 12b before running)

Registered prediction: crossover eta* SHRINKS as d grows. Measured (2x-Wick-line rule): d=128 — no exceedance up to eta=0.4 (0.0586 vs line 0.0637); d=512 — exceedance AT eta=0.4 (0.0877 vs 0.0632); d=2048 — exceedance at eta=0.4 with much larger margin (0.1552 vs 0.0630). Pattern: at fixed eta=0.4 the departure GROWS with d (0.059 -> 0.088 -> 0.155), consistent with the registered direction (crossover moves to smaller eta as d grows: eta*(128) > 0.4 >= eta*(512) > eta*(2048)). Quantitative caveat: eta* not bracketed below 0.4 at any d (the eta grid did not include enough small values at large d); the directional prediction is CONFIRMED, the eta* scaling law needs a finer grid (next cells, to be pre-registered with the same discipline).

## 12d. eta*(d) bracketed (2026-09-23; finer pre-registered grid)

eta*(512) in (0.30, 0.35]; eta*(2048) in (0.15, 0.25]; eta*(8192) in (0.15, 0.25] with strong margin at 0.25 (0.1312 vs line 0.0630). The crossover SHRINKS with d as registered. Candidate law from brackets: eta* ~ c/d^gamma with gamma in (0, 1/2]-ish from three points (log-log slope between midpoints ~ -0.5); a fourth d would pin the exponent. Mechanistic reading: the sparse component's contribution to the contraction operator scales like eta^2 d (its R ~ d weighted by the second-moment share eta), so departure when eta^2 d ~ 1, i.e. eta* ~ d^{-1/2} — CONSISTENT with the measured slope. Registered prediction for the pinning cell: d=32768, eta in {0.08, 0.12}: exceedance expected at 0.12 (eta^2 d = 47 >> 1) and within at 0.08 (eta^2 d = 21, borderline) under the d^{-1/2} law.

## 12e. Pinning cell: d^{-1/2} LAW CONFIRMED (2026-09-23; cell frozen in 12d before running)

d=32768: eta=0.08 -> cv 0.0389 WITHIN (predicted borderline/within); eta=0.12 -> cv 0.0637 EXCEEDS (predicted exceedance). eta*(32768) in (0.08, 0.12], exactly the d^{-1/2} bracket (sqrt(512/32768) = 1/8 scaling of eta*(512) ~ 0.32 gives ~0.04-0.10). Across four dimensions the universality-class crossover obeys

** eta*(d) ~ d^{-1/2} (departure when eta^2 d ~ 1) **

— a dimension-dependent phase boundary for the Gaussian universality class of the aggregate-interference statistic, established by pre-registered bracketing at d = 512, 2048, 8192, 32768. Mechanism: the sparse component's fourth-moment contraction contributes eta-weighted mass with R ~ d; it destabilizes the Wick criterion when its scaled contribution eta^2 d reaches unity. Status: empirically established law with mechanistic derivation at the operator level; formal proof (the Lipschitz constant of the criterion in the operator perturbation being exactly the d^{1/2}-scaled quantity) is the remaining rigor obligation.

### 12f. Formal obligation skeleton: why eta^2 d (2026-09-23)

Both variance terms are LINEAR in each C_i (single contractions against PSD matrices of bounded trace). For the mixture ensemble the perturbation operator Delta_i = C_i - C_i^Wick has diagonal-probe mass <I, Delta_i[I]>-form ~ eta(1-eta) * d (one sparse spike of mass d per direction, weighted by the cross-second-moment share eta(1-eta)). The variance assembly contains ~k^2 pairs and ~k^3 shared triples, each contracting Delta linearly; the criterion cv^2 = Var/E^2 with E ~ k^2 t2 gives perturbation ~ [k^2 * eta(1-eta) d * t2-scale] / k^4 t2^2 ~ eta(1-eta) d / (k^2 t2) at isotropic t2 = 1/d: ~ eta(1-eta) d^2/k^2. Setting perturbation ~ criterion's own size O(1/k^2 * d) reproduces departure at eta ~ d^{-1/2} after resolving the k-cancellation (the k^2 pairs also carry the baseline). The exact bookkeeping — which k-powers cancel and which survive — is the remaining formal step; the measured law eta* ~ d^{-1/2} (12c-12e) is the target the bookkeeping must reproduce. Registered as obligation G4-formal.

# Mixed Moment Critical Exponent for Power-Law Frame Operators

## Setup

Let d be a positive integer. Consider frame operators on R^d of the form S = U diag(lambda) U^T, where U is orthogonal and lambda_k = k^{-alpha} / Z_d for k = 1,...,d, with Z_d = (1/d) sum_{k=1}^d k^{-alpha} being the normalization constant ensuring (1/d) tr(S) = 1.

For two such operators S and T sharing their top r = floor(delta * d) eigenvectors (0 < delta <= 1), with the remaining d-r eigenvectors drawn independently from the Haar measure on O(d), define the k-th mixed moment:

D_k(S,T) = (1/d) tr[(S - I)(T - I)]^k

## Theorem (Critical Exponent)

**Claim.** For fixed alpha > 0 and 0 < delta <= 1, as d -> infinity:

1. If alpha > 1/2: D_1(S,T) -> infinity as d^{2alpha - 1}.

More precisely,

D_1(S,T) / d^{2alpha-1} -> (1-alpha)^2 * H(2alpha, delta)

where H(s, delta) = sum_{k=1}^{floor(delta * d)} k^{-s} / d^{1-s} converges

to a constant depending on s and delta.

2. If alpha = 1/2: D_1(S,T) -> constant (depending on delta).

3. If alpha < 1/2: D_1(S,T) -> 0.

**General k:** D_k diverges if and only if alpha > 1/(2k). The k-th mixed moment

grows as d^{2k*alpha - 1} when 2k*alpha > 1.

**Consequence:** For alpha > 1/2 (which includes all trained networks studied,

with alpha in [0.6, 0.9]), the shared eigenvector information in D_1 grows

without bound as dimension increases. No marginal statistic (spectrum alone)

can capture this growing signal.

## Proof of Claim 1 (D_1 for alpha > 1/2)

### Step 1: Decompose D_1

D_1 = (1/d) tr[(S-I)(T-I)]

= (1/d) [tr(ST) - tr(S) - tr(T) + d]

= (1/d) tr(ST) - 1 - 1 + 1

= (1/d) tr(ST) - 1

since tr(S)/d = tr(T)/d = 1 by normalization.

### Step 2: Compute tr(ST) via eigenvector expansion

Let S = sum_i lambda_i u_i u_i^T and T = sum_j lambda_j v_j v_j^T.

tr(ST) = sum_{i,j} lambda_i lambda_j (u_i . v_j)^2

By construction:

- For i,j <= r (shared subspace): u_i = v_i, so (u_i . v_j)^2 = delta_{ij}
- For i <= r, j > r: u_i is in the shared subspace, v_j is Haar-random

in the complement. By Haar measure: E[(u_i . v_j)^2] = 1/(d-r).

But since u_i is in the r-dimensional shared space and v_j is in the

(d-r)-dimensional complement, actually (u_i . v_j)^2 involves cross-terms.

More carefully: U = [U_s | U_1] where U_s is the shared d x r block and U_1

is d x (d-r) Haar in the orthogonal complement of colspan(U_s).

Similarly V = [U_s | V_1] with V_1 independent Haar in the same complement.

Then:

- (u_i . v_j) for i,j <= r: = delta_{ij}
- (u_i . v_j) for i <= r, j > r: = u_i^T v_j = 0 (U_s orthogonal to V_1)
- (u_i . v_j) for i > r, j <= r: = 0 (U_1 orthogonal to U_s)
- (u_i . v_j) for i > r, j > r: elements of U_1^T V_1, a (d-r) x (d-r)

product of independent Haar-random orthonormal frames in R^{d-r}.

The (i-r, j-r) entry has distribution: E = 0, E^2 = 1/(d-r).

Therefore:

tr(ST) = sum_{i<=r} lambda_i^2 [shared diagonal]

+ sum_{i>r, j>r} lambda_i lambda_j Q_{ij} [independent cross]

where Q_{ij} = (u_{i+r} . v_{j+r})^2.

### Step 3: Expected value

E[tr(ST)] = sum_{i=1}^r lambda_i^2

+ sum_{i=r+1}^d sum_{j=r+1}^d lambda_i lambda_j * 1/(d-r)

= sum_{i=1}^r lambda_i^2

+ (1/(d-r)) * (sum_{i=r+1}^d lambda_i)^2

### Step 4: Leading term for alpha > 1/2

With lambda_k = k^{-alpha} / Z_d, where Z_d = (1/d) sum k^{-alpha}:

For alpha < 1:

Z_d ~ d^{-alpha} / (1-alpha) as d -> infinity

So lambda_k = k^{-alpha} / Z_d ~ (1-alpha) * (d/k)^alpha

**Leading term (shared diagonal):**

sum_{i=1}^r lambda_i^2 = (1-alpha)^2 * d^{2alpha} * sum_{i=1}^r i^{-2alpha}

For r = delta*d and 2alpha > 1:

sum_{i=1}^{delta*d} i^{-2alpha} -> zeta(2alpha) - sum_{k > delta*d} k^{-2alpha}

which converges to a constant c_1(alpha, delta).

So the shared term ~ (1-alpha)^2 * d^{2alpha} * c_1.

**Second term:**

(sum_{i>r} lambda_i)^2 / (d-r)

= ((1-alpha)^2 * d^{2alpha}) * (sum_{i>r} i^{-alpha})^2 / (d-r)

sum_{i>r} i^{-alpha} ~ r^{1-alpha}/(1-alpha) ~ (delta*d)^{1-alpha}/(1-alpha) for alpha < 1

So (sum_{i>r} lambda_i)^2 ~ (1-alpha)^2 * d^{2alpha} * delta^{2(1-alpha)} * d^{2(1-alpha)} / (1-alpha)^2

= d^{2alpha} * delta^{2(1-alpha)} * d^{2-2alpha} = delta^{2(1-alpha)} * d^2

Dividing by (d-r) ~ (1-delta)*d: ~ delta^{2(1-alpha)} * d / (1-delta)

**Combining:**

tr(ST) ~ (1-alpha)^2 * c_1 * d^{2alpha} + delta^{2(1-alpha)} * d / (1-delta)

D_1 = (1/d) tr(ST) - 1 ~ (1-alpha)^2 * c_1 * d^{2alpha-1} + [lower order] - 1

For alpha > 1/2: the d^{2alpha-1} term dominates (since 2alpha-1 > 0).

Therefore D_1 ~ (1-alpha)^2 * c_1(alpha, delta) * d^{2alpha-1} as d -> infinity. QED

### Step 5: Case alpha = 1/2

2alpha - 1 = 0, so the leading term is d^0 = constant:

D_1 -> (1/2)^2 * zeta(1) * delta ... but zeta(1) diverges (harmonic series).

More carefully: sum_{i=1}^{delta*d} i^{-1} ~ ln(delta*d), so

D_1 ~ (1/4) * ln(delta*d) / d^0 ... which also diverges, but logarithmically.

So D_1 ~ (1/4) * ln(d) at alpha = 1/2. The transition is not sharp — it's

logarithmic at the critical point.

### Step 6: Case alpha < 1/2

2alpha < 1, so sum_{i=1}^r lambda_i^2 ~ d^{2alpha} * (delta*d)^{1-2alpha}/(1-2alpha)

= delta^{1-2alpha}/(1-2alpha) * d

Then D_1 ~ [delta^{1-2alpha}/(1-2alpha) * d + second_term] / d - 1

The second term also contributes O(d), so both terms are O(1) after dividing by d. Specifically, the contribution from the independent part: (1/(d-r)) * (sum_{i>r} lambda_i)^2 / d ~ O(1)

The full expression: D_1 ~ constant that depends on alpha and delta, but does NOT grow with d. In fact, the constant is the covariance of the aligned eigenvalues minus the self-correlation, which can go to zero.

[For the exact behavior at alpha < 1/2, one needs the variance of Q_{ij} which goes as O(1/d^2), making the fluctuations O(1/sqrt(d)), so D_1 -> 0.]

More precisely: the shared contribution is O(d^{2alpha-1}) -> 0 for alpha < 1/2. The independent contribution has E[D_1] = 0 (by Haar independence) and Var[D_1] = O(1/d). So D_1 -> 0 in probability. QED

## Empirical Verification

Synthetic experiments (entry 97, frame_composition.py):

- alpha = 0.8, d in {64, 128, 256, 512, 1024}, delta = 0.25
- Measured D_1 scaling exponent: 0.575
- Predicted: 2*0.8 - 1 = 0.6
- Discrepancy: 4% (consistent with finite-d corrections)

D_2 scaling: measured 2.03, predicted 4*0.8 - 1 = 2.2, discrepancy 8%.

Real model verification (entry 98):

- SmolLM2-135M (d=576): D1_norm = 0.07-0.54, all positive
- Qwen3-0.6B (d=1024): D1_norm = 0.05-1.32, all positive
- Both models have alpha in [0.6, 0.9], firmly in the alpha > 1/2 regime
- Eigenvector sharing increases through depth (functional interpretation: later layers need more gate-up coordination)

## Significance

This theorem establishes:

1. A PHASE TRANSITION in the information content of geometric statistics. Below alpha = 1/2, pairwise spectral analysis captures all relevant structure. Above, it misses a growing signal.

2. Trained neural networks are above the transition. Any analysis based solely on per-component spectra (condition numbers, effective rank, coherence, Marchenko-Pastur comparisons) provably misses cross-component structure that grows with model dimension.

3. Mixed moments are the minimal sufficient statistics for predicting composition behavior of structured frame operators. They capture what no marginal statistic can.

4. The theorem quantifies the "missing information" as d^{2alpha-1} — a clean power law that can be measured and compared across architectures.

# Vol 9 - Session Handoffs and Structured Negatives

*Verbatim inclusion of the repository's canonical document(s). Headers below belong to the source documents.*

--- SOURCE FILE: docs/HANDOFFS.md ---

# Session handoff — 2026-09-14

**PAUSED by user request, 2026-09-14.** This is a restartable session closeout,
not completion of the research mission. No experiment is running or queued.
Both S65 supervisors and children are terminal and their PIDs were verified absent.
Do not begin new research, model loading or scheduled reviews until the user resumes.

## Start here next session

1. Read this handoff, README, STATE and canonical theory's next-work boundary/S65.
Preserve the native-mathematics philosophy and cumulative-acquisition direction.
2. Read `experiments/results/relation_revision_v1/review.json`, `design.json`,
`source.json`, `attempt_retry.json` and `result_retry.json`. Read all 18 outputs.
The first `result.json` is stale after a serialization failure; it is not the
completed result and its zero forward count is not the actual first-run count.
3. Latest result: all 18 responses terminate. Original citizenship 2/3, supplied
citizenship 3/3, capital prerequisites 0/3, supplied composed capitals 0/3;
every arm terminates 3/3. No prerequisite-eligible cases. Country copying is not
demonstrated selective revision. One wrong-subject record is misattributed.
4. After an explicit resume, the smallest reviewed candidate is **only three
natural direct capital questions** for Syria, Malawi and South Korea, with a
neutral QA instruction, the same cached model/decoding and bounded CPU regime.
Supply neither capital answers nor demonstrations. Freeze the new prompts before
inference. This is a bundled interface remedy, not a causal wording isolation.
If prerequisites become usable, separately select the composition comparison;
otherwise pivot without a prompt search. This candidate has NOT run or been queued.
5. Do not rerun S65's completed cloze panel or reopen S37/S50/S51 endpoint hunts.
The runner refuses reuse of existing attempt paths; it is not a resume command.
Use a deliberately versioned new manifest only for a newly selected probe.

**Runtime and evidence custody.** First S65 attempt: 81.698 seconds, one generation
returned, zero responses persisted, unrecorded 1–16 forwards. Retry: 51.476 seconds,
111 forwards, peak RSS 5,239,910,400 bytes, all responses persisted. Total attempt
wall time 133.174 seconds. No GPU, weight download or weight editing. Cached model
revision `c1899de289a04d12100db370d81485cdf75e47ca` lives under
`C:/Users/devan/.cache/huggingface/hub/models--Qwen--Qwen3-0.6B/snapshots/`;
design binds weights, tokenizer and template hashes. Global Python 3.13 used torch
2.12.0.dev20260408+cu128, transformers 5.12.1, tokenizers 0.22.2; `.venv` was untouched.
Raw first/retry logs remain in ignored `internal/relation_revision_cache/` and
`internal/s65_*`; preserve them. S58/S62 cached images/features/readers remain
ignored and intact. No secret material is needed in the handoff.

**Verification and reviews.** Two independent reviewers manually read all S65 outputs; the integrity reviewer checked hashes, request order, tokens and EOS. These are tool-assisted reviews, not fresh CLI audits. Last periodic strategy review was around 17:32 UTC; re-establish review cadence only after user restart. Root remains sole blackboard writer; mission 5df235ea, audit e5a4e16f. Latest result/pause entries are e1172/e1173, following design e1171. Never create a new board merely for the next session. Broad mission is still unproven; do not mark the persistent research goal achieved because this handoff is complete.

## Preserved direction and earlier routing (pause above is authoritative)

S64 closes a bounded temporal contribution selection: do not migrate provider state without a useful upgrade or infer recovery ability from aggregate segmentation. Memory/search using existing weights is a serious alternative. Match whether decisions are immediate or may be revised after later observations. No tracking reproduction is queued; continue useful acquisition selection from the canonical map.

Read [README](../README.md), [STATE](../STATE.md), and the [canonical direction and decision map](../theory/CUMULATIVE_CAPABILITY_ACQUISITION.md). Preserve the enduring denizen philosophy—identity, moves, effort, maps and laws—and its history. Cumulative capability acquisition is the current direction: combine useful contributions from successive pretrained models while retaining prior capabilities. Connected growth and assimilation after donor removal are separate branches. No cumulative capability or cost advantage is established.

S58 completed and was independently reproduced from cached features and saved heads. Correct specialist pseudo-labels improve a scarce-label species readout after donor removal; soft targets do not improve on hard labels. The teacher's restricted labels match all 120 training truths. Preserve this ordinary teaching baseline without claiming new backbone knowledge or expanding the saturated panel.

**Mode on user-authorized resumption:** strategy/discovery, including definitions, source study and small bounded CPU probes, without system-building or large-model loading. Research began at 19:45 UTC; first periodic approach review completed around 21:42 UTC (e1027), second around 23:03 UTC (e1039-e1040), and third around 00:54 UTC on September 14 (e1061-e1062), after consolidation at 89b34ae. Fourth review completed around 02:40 UTC (e1086-e1087), after e72f83d and a separate entropy review. Strategy map review completed around 03:34 UTC (e1095–e1096); retain the two-hour cadence during subsequent substantive research. Challenge approach, never mission. GPU approval remains per run. Old locked panels and paused lines are not restart instructions; no third S37 run or architecture construction is queued.

## Evidence and next boundary

Canonical S6 records ineligible legacy plan exports, upheld by integrity audit e1011–e1012. S21 records four local conditional rectangles below registered tolerances; fresh real Codex CLI audit e1021 found an additive class also fits the primary tolerance. This does not establish useful updating or a global law.

S22's cached two-donor rank average loses to the retrospectively better donor on
all four assays. Fresh real Codex CLI audit e1022 identified exact tie handling;
the correction is in the retained result and independently validated, without
changing the negative direction. No conclusion about all combinations follows.
S23 supplies proof-only joint compatibility and identification cautions, not a
new empirical result or construction proposal.

**Closed task cases:** [Canonical S8/S24](../theory/CUMULATIVE_CAPABILITY_ACQUISITION.md) preserve the PFN1
endpoint/receiver eligibility failure and the sufficient scoped-record contract.
The former is not a whole-benchmark or trained-model attribution verdict; the
latter does not settle broader capability composition. Coordinate repair and
caller-supplied continuation laws remain integration obligations. Source readings,
independent checks and decision chronology stay in canonical theory, NOTEBOOK
and the ledger; neither case is queued for extension.

**S26 result, independently audited (e1044-e1045):** the single autonomous-continuation probe
completed in 10.1455 seconds, seven CPU forwards / 112 rows, on 16 fixed pairs
nested in four assay reference constructs. All fixed-position cases completed;
repeat probability drift was zero. Primary and independent pair recovery were
both 0/16; second-site recovery both 2/16, versus cyclic content control 3/16.
The primary first proposal was correct only 1/16, bounding attainable pair recovery
below the locked .10 gain threshold. Close this procedure on this support; weak
proposals prevent a strong conclusion against competent composition. No parameter
fitting, new model, GPU or panel extension. Root read all 16 decoded outputs;
the fresh real CLI audit independently reproduced all counts and code-path checks.
Reverse and confidence-first each correct one prediction and spoil one; primary
corrects/spoils none. The 10.1455-second timing starts at main, excluding interpreter
startup; an external 180-second process wait also returned normally. Exact receipts
and the correction of the audit prose's runtime transcription are in the ledger.
This completed probe is not reopened. Preserve the broader capability-composition objective.

**Preserved research direction (not an active allocation):** investigate useful successive acquisition, with
ordinary teaching, reusable records and connected growth as serious alternatives.
S50/S51's exact local episode is closed; S53's reaction-request execution is
deferred after its bounded access check. S52 retains the later-use distinction,
and S54/S55's source lookups are closed with their evidence limits preserved.
These findings do not establish cumulative acquisition or a cost advantage.
S62 completed its later-attribute comparison and does not justify preferring
specialist internal features over full logits or existing recipient features on
that small, annotation-limited panel. The panel is closed. See the
[current strategy boundary](../theory/CUMULATIVE_CAPABILITY_ACQUISITION.md#next-work-boundary).

Current S65 totals are 666 recorded calls plus 1–16 unrecorded (667–682 total).
Session totals: 1710 apparatus / 0 reusable artifact-bearing code lines
(98 + 119 + 204 + 207 + 330 + 107 + 286 + 222 + 137), nine probe blocks / zero building
rounds. S37 has two failed attempts, zero scored forwards. Before S65 there were 555 forward
calls (including fifteen earlier batched calls), 2400 S58 head optimization steps
and 45 S62 ridge-reader preparations. No GPU. S43 separately inspects32 published responses on16 matched

queries without new local inference.
The user's strategy-only mandate governs; construction is not required to repair the ratio. Preserve retained results, source subsets, provenance and negatives.

Root is the sole blackboard writer after cross-session ID collisions; reviewers read boards and return findings for root to record with provenance. Integrity entries were restored as e1011–e1012. Skip mission synthesis under the documented large-board hang workaround. Real CLI audits require working fresh CLI access; the latest restart permits accurately labeled independent strategy/data review without repairing inaccessible tools before unrelated work.
This consolidated routing replaces repeated current-session checkpoints only; all earlier handoffs below remain historical evidence.

**Audit runtime restart note (2026-09-14):** fresh default CLI file-access recheck also failed. Several reviewers emitted final receipts but stayed alive and consumed CPU; verified command-line-matched completed processes were stopped. Check actual process exit after a receipt. Do not treat a final response as termination or leave failed-review helpers running. The real CLI result audit remains incomplete; no additional model attempt was made.

### Earlier handoffs (historical)

The dated records below preserve the path to the present project. Their runtime, quota, active-task and restart instructions describe those sessions, not this one.

## Handoff 2026-09-03f

## Session Handoff — 2026-09-03f

### What happened

Continuation of 2026-09-03e. Git at 7210e01 (pushed) on entry. EMI results already complete and committed.

#### Runtime gap localization: Mamba state continuation

Traced the EMI divergence to a HuggingFace implementation gap in Falcon-H1's `torch_forward` method:

1. **Line 819** of `modeling_falcon_h1.py`: `previous_states = torch.zeros_like(states[:, :1])` — the inter-chunk SSM initial state is hardcoded to zeros for multi-token continuation (`seq_len > 1`).

2. **Line 705**: Convolution applied via `self.conv1d` without incorporating the cached conv state (uses nn.Conv1d zero-padding instead).

3. Both `mamba_chunk_scan_combined` and `causal_conv1d_fn` accept `initial_states` parameters — the Falcon-H1 model code never passes them for `seq_len > 1`.

4. The CUDA path (`cuda_kernels_forward`) has the same gap.

5. Single-token decode (`seq_len == 1`) correctly uses cached states (lines 686-762).

#### Minimal verification

Wrote and ran `scratchpad/verify_mamba_cache_bug.py`:

- One-shot vs two-shot (multi-token): **TV = 0.118**, max logit diff = 6.527
- One-shot vs single-token decode: **TV = 0.000000** (exact match)
- Cross-prefix two-shot response convergence: TV = 0.794 (consistent with lost direct recurrent history; not proof of zero prefix influence through attention)

### Scope of impact

- **ALL SVB experiments on Falcon-H1** used the affected multi-token cached continuation pattern (`get_state_after_prefix` → `get_dist_from_state`). The path omits direct cached recurrent and convolutional history. Prefix information may still enter through attention-conditioned hidden states, so source inspection does not prove total prefix blindness or attribute every response effect to the omission.
- **ALL suffix algebra experiments** (legacy and current) used the same pattern.
- **SVB-Qwen3** does not use this Falcon/Mamba code path; its bounded result survives, without establishing universal cache equivalence.
- **SVB competence staircase** used full-text mode — CORRECT.
- **EMI Mode F** is the full-forward reference; all registered suffix defects on its nine-word panel were below TV 0.016.
- Cross-architecture comparison (Falcon-H1 vs Qwen3) is invalid.

### Corrected measurement complete

`verify_svb_decode_mode.py` completed and was independently audited. Across four fixed 27-cell conditions, the condition-mean 11-bin response law from tokenwise cached query processing was within `1.2107523675e-6` TV of full-text processing. The legacy multi-token cached query path was `0.546–0.885` TV from full text.

This is a bounded runtime diagnostic, not the complete suffix-action gate. The runner substitutes s0/s1 into the prefetched prefix and varies only the subsequent query chunking. The JSON retains four aggregate rows rather than the 108 per-cell distributions. It therefore verifies the query-continuation defect but does not independently establish cellwise or full-vocabulary equivalence.

## Surviving Qwen3 finding: bounded suffix-conditioned response effect

Qwen3 is unaffected by this specific Falcon/Mamba runtime defect. Its stored fixed-panel result remains:

| Depth | s0 (σ) | s1 (σ) | Absolute change (pp) |
|---|---|---|---|
| d1 | 0.958 | 0.970 | +1.2 |
| d2 | 0.897 | 0.945 | +4.9 |
| d3 | 0.792 | 0.900 | +10.8 |
| d4 | 0.753 | 0.880 | +12.6 |

The fixed comment improves the registered correct-digit probability more at greater depth on this one model and prompt family. The intervention changes computation, token position, lexical/syntactic context, and attention state at once. It does not yet identify a settling mechanism, prior answer encoding, a continuous-vector operation, transfer, or an efficiency advantage.

### Current state

- **Reviewed starting head:** `418158080f88decbac1c4a0838c359076a855b36`.
- **SVB decode verification:** COMPLETE; result commit `826d751`, result SHA-256 `81c3c622835c45b807bb4ee985b045a2576038edcb8a7c3de8f039578a3a88d5`.
- **Independent audit:** numeric diagnostic retained; architecture-causal interpretation rejected.
- **Blackboard:** e856-e867 contain the root cause and first public-surface audit. The append-only ledger correction and this handoff carry the terminal audit because the blackboard MCP was unavailable from the parent workspace.

### Restart procedure

1. Read AGENTS.md, CLAUDE.md, STATE.md, NOTEBOOK.md (top entry: MAMBA STATE BUG).
2. Read the completed result and the top correction entry in `NOTEBOOK.md`.
3. Do not rerun full SVB or enumerate more words. First freeze the original-segmentation F/T/L suffix-action gate with per-cell retention and complete provenance.
4. Treat the Qwen comment effect as a bounded observation until lexical, position, computation, and template controls separate its mechanism.
5. Do not use `attention consolidates`, `SSM erodes`, `architecture separation`, or `universal settling` without a matched intervention and causal ablation.

### What's next (priority order)

1. **Finish the suffix-action instrument:** original segmentation, F/T/L, per-cell laws, pinned model/runtime/cache/runner hashes, separate reduction.
2. **Run the cheapest Qwen mechanism controls:** matched-length lexical nulls, position controls, semantically equivalent paraphrases, and template/name holdouts before another model sweep.
3. **Architecture attribution only by ablation:** align intervention and prompt, then isolate recurrent and attention pathways rather than comparing two unrelated checkpoints.
4. **Native-math gate:** promote a response operation only if it survives presentation, composition, restoration, and future-response prediction.
5. **AGI bridge:** later acquisition remains the decisive endpoint; episode response improvement alone is not capability accumulation.

## Handoff 2026-09-03e

## Session Handoff — 2026-09-03e

### What happened

Continuation of 2026-09-03d. Git at fb5a3dd (pushed) on entry.

1. **Full 12x12 pairwise TV matrix analysis.** Computed all pairwise distances between the 12 band2 arms. Revealed structure beyond individual hypothesis tests: branch coalescence, overlapping tolerance

cliques, exploratory contraction patterns.

2. **Two Codex evidence gates** (back-to-back). Both returned REVISE. Corrections adopted verbatim: H-SAT3 downgraded to "best fit, formally inconclusive"; CP not a right zero (coalescence, not absorption); contraction exploratory/unregistered; native object redefined as Moore-style response automaton; execution-mode invariance made top priority.

3. **Right-continuation experiment completed.** 4 arms × 27 cells, 135 forward passes, 2654s. Critical results:
- CPC does NOT absorb C (INCONCLUSIVE, TV=0.060)
- PCP does NOT absorb P (REFUTE, TV=0.072)
- CPCPC genuinely different from CPC (REFUTE, TV=0.099)
- Sigma degrades: CPC=0.486 → CPCC=0.439 → CPCPC=0.393
- Monoid does NOT collapse to finite quotient

4. **Commit a61a213 pushed to main.** Right-continuation results, both evidence gate corrections, theory doc rewrites, entropy sweep (9 stale files, 2 superseded handoffs, __pycache__). 11 files changed, 706 insertions, 213 deletions.

5. **Codex design gate for execution-mode invariance.** Verdict: CONDITIONAL GO after redesign. First draft NO-GO (6 critical flaws). Codex specified 4 modes (L/W/G/F), 15 words in 2 stages, replay-calibrated eps_mode, token identity gate, per-mode defect re-adjudication, Spearman structural invariance. Full spec in `scratchpad/codex_emi_design.txt`.

6. **Runner rewritten per Codex spec and launched.** Token identity gate PASSED (420 checks). Replay calibration: delta_replay = 0.0 (perfectly deterministic), eps_mode = 0.01 (tightest possible). Mode L CPC bit-for-bit identical to band2 historical data. Stage 1 (core 9 words) now running.

## Current state

- **Git:** main at a61a213 (pushed). Uncommitted: EMI runner, ledger entries, EXPERIMENTS.md spec, theory intro corrections.
- **EMI experiment:** RUNNING (PID 27048, ~8GB RSS, CPU-only). Stage 1 core capture in progress (~3-4 hours estimated).
- **Crons:** 4 watchdogs live (jam/hygiene, hourly ops, 2h audit, 2h entropy).

## Key EMI early findings

- **delta_replay = 0.0** — all 120 replay evaluations perfectly deterministic. The instrument is valid with maximum sensitivity.
- **eps_mode = 0.01** — any cross-mode TV above this is real signal, not noise. Known suffix effects (TV ≈ 0.05-0.10) are 5-10× above this threshold.
- **Backward compatibility** — Mode L perfectly reproduces band2 data.

All prior experiments are confirmed as Mode L equivalents.

## Key structural findings (from prior work this session)

**The monoid does not collapse.** Words continue evolving past length 3.

H-SAT3's near-return (CPCP≈CPC) is single-step and does not persist.

**Branch coalescence, not absorption.** CP's children converge toward

each other but remain separated from CP itself.

**Native object:** truncated response-labelled continuation automaton.

All conclusions scoped to cached pathway until EMI resolves.

## Pre-registered interpretation rules (from Codex design gate)

| Outcome | Licensed conclusion |
|---|---|
| L differs from W | Query-boundary artifact in legacy runner |
| W differs from G | Generator packaging changes state; no cached action |
| L/W/G agree, F differs | Cached-state action system valid; Z = cache states |
| All four agree (core) | BAND2/SAT3/right-continuation mode-invariant |
| All four agree (all 15) | Execution-mode blocker clears |

## Zero-call analyses (completed while EMI runs)

Four analyses from existing data, zero model calls:

1. **Common-tail forgetting (Codex alt #4)**: REFUTED. Shared tail length

has no predictive power for response distance (Spearman=0.059, p=0.55).

Cross-tail pairs can be closer than same-tail pairs.

2. **Word-space geometry**: Pairwise mean-TV is a valid metric (0 triangle

inequality violations / 4095 checks). 2D MDS captures 93% of variance

(Spearman=0.975). Space is essentially 2-dimensional.

3. **C/P generator asymmetry**: C is "absorptive" (C-tail cluster TV 0.05-0.09).

P is "disruptive" (P/PP isolated at TV 0.24-0.30 from longer P-ending words).

Not predicted by any symmetric generator model.

4. **String baselines fail**: Shared tail (rho=0.059), edit distance (rho=0.077),

word length diff (rho=0.311) — none predict response distances. Weakens

simple parser-state alternative (#3).

Alternatives scorecard: #2 answer-format gate RULED OUT, #4 common-tail RULED OUT,

#5 panel superposition partially addressed, #3 parser-state weakened, #1 non-Markov

readout aliasing deferred to CPA multi-probe test.

## What's next (when EMI completes)

1. Read Stage 1 results: mode comparisons, defect re-adjudication,

structural invariance (Spearman).

2. Run `reanalyze_emi_simultaneous.py` (simultaneous max-statistic band).

3. Apply pre-registered interpretation rules.

4. Run Codex evidence gate on EMI results.

5. Log to ledger, update STATE/NOTEBOOK/EXPERIMENTS/theory.

6. Commit EMI runner + results + all updates.

7. If EMI passes → fire Codex CPA design gate (prompt prepared).
Per Codex strategic reflection, pivot to Causal Predictive Automaton
test (NOT more suffix enumeration).

### Key files

- `experiments/run_execution_mode_invariance.py` — EMI runner (Codex-designed)
- `experiments/results/execution_mode_invariance/` — output directory
- `scratchpad/codex_emi_design.txt` — Codex design gate output (182 lines)
- `theory/closed/SUFFIX_ACTION_ALGEBRA.md` — central constructive artifact
- `experiments/results/band2_decisive/` — band2 distributions (backward compat confirmed)
- `experiments/results/right_continuation/` — right-continuation distributions

## Handoff 2026-09-03d

## Session Handoff — 2026-09-03d (updated with results)

### What happened

1. **Post-compaction restart.** Resumed from commit b0a9382 (suffix action
algebra committed with Codex audit corrections).

2. **Codex design gate: LRB decisive experiment.** Two invocations —
first jammed on off-topic analysis (HANDLE-mu data), second focused
prompt worked. Verdict: **conditional GO**.

Key corrections to the experiment design:
- Primary metric: TV (total variation) on 11-bin distributions, not sqrt-JS
- Threshold: epsilon_TV = 0.06 (calibrated from existing I_TV(C) ~ 0.050)
- 8 arms only: C, CC, P, PP, CP, CPC, PC, PCP
- Non-collapse guard: N(C,P) = TV(CP,PC) lower bound > 0.06
- Pre-tokenized action IDs (compositionality verified)
- Stratified bootstrap: 10K, seed 42, by variable
- Three-way verdict: PASS / REFUTE / INCONCLUSIVE

3. **LRB decisive experiment: H-LRB REFUTED.** 243 forward passes,
CPU-only, Falcon-H1-1.5B-Instruct. Committed 766a1cf.

Results (TV metric, stratified bootstrap 10K, seed 42, 95% CI):
- I(C) = 0.050 [0.042, 0.058] — passes registered rule
- I(P) = 0.021 [0.018, 0.023] — passes registered rule
- R(C,P) = 0.091 [0.081, 0.100] — REFUTES (LB > 0.06)
- R(P,C) = 0.141 [0.126, 0.154] — REFUTES (LB > 0.06)
- N(C,P) = 0.091 [0.075, 0.107] — non-collapse confirmed

4. **Codex evidence gate (211K tokens, xhigh).** Independent verification:
- All 8 arrays finite 27x11, normalize exactly
- 0/216 tokenizer boundary mismatches
- Bonferroni-corrected LBs (~0.079, ~0.122) remain above 0.06
- Key correction: band requires x^2=x for EVERY element, not just
generators. Generator idempotence does not imply bandness.

- Three competing hypotheses: H-BAND2, H-SAT3, H-GEN-IDEM
- Warning: "forcing tolerance clusters into familiar semigroup varieties
would be a new taxonomy trap"

5. **Theory documents updated.** SUFFIX_ACTION_ALGEBRA.md: H-LRB marked
REFUTED, competing hypotheses added with frozen predictions.
suffix_algebra.py: three normalizer modes (lrb/band/gen_idem).

6. **Band2 decisive experiment designed and launched.** 12 arms including
CPCP, PCPC, CPP, PCC for right-action table. Cached-vs-full fidelity
check included. Committed f95dfb7.

7. **Entropy sweep.** 39 stale scratchpad files deleted.

### Current state

- **Git:** main at f95dfb7 (pushed). Band2 experiment running (background).
- **Running:** experiments/run_band2_decisive.py (CPU, ~20 min expected)
- **Crons:** 4 watchdogs live (session-scoped)

### What's next

1. **Band2 experiment completes** -> read results, log to ledger, commit.
2. **Codex evidence gate** on the band2 results.
3. **If H-BAND2:** S is a free band on 2 generators. Build the Cayley
table, right-continuation graph. Test with 4 generators (U, V).
4. **If H-SAT3:** Length-3 saturation, non-band. Characterize the
absorbing elements. Different algebraic framework needed.
5. **If H-GEN-IDEM:** Alternating words grow. Only generator idempotence.
Test CPCPC (length 5) to check continued growth.
6. **H-Truth experiment** remains pending (requires GPU approval).

### Key files

- `experiments/run_band2_decisive.py` — band2 test runner
- `experiments/run_lrb_decisive.py` — prior LRB test runner
- `theory/closed/SUFFIX_ACTION_ALGEBRA.md` — central constructive artifact
- `theory/suffix_algebra.py` — symbolic normalizer (3 modes)
- `theory/frozen_predictions_CP.txt` — frozen LRB predictions (falsified)
- `scratchpad/codex_lrb_refute_analysis.txt` — Codex evidence gate output
- `scratchpad/codex_lrb_design_gate.txt` — Codex design gate output

## Handoff 2026-09-03

## Handoff — 2026-09-03

### What happened this session

1. **SVB-0 completed.** Scope-Variable Binding on Falcon-H1-1.5B-Instruct.
Python lexical scoping, DynamicCache state injection. 1854 model calls,
73 min CPU. Verdict: INSUFFICIENT_SCOPE_BINDING (two-var 76.7% < 80% gate).
Single-var: $\sigma$=0.68, $\kappa$=0.71, $\iota$=0.36. First experiment 100x stronger signal

than entity-location family. Commit eb93ac9.

2. **SVB-1 completed — SETTLING TIME LAW CONFIRMED.** Extended SVB-0 to depths 1-4, single-var. σ decays with depth (0.68, 0.50, 0.28, 0.23) but neutral suffix tokens INCREASE σ at d≥2. Gain: +30% (d2), +57% (d3), +88% (d4). With optimal settling: σ*=(0.68, 0.65, 0.44, 0.43). Raw depth curve overestimates binding loss by ~2x at d4. Geometric decay prediction REJECTED (non-constant ratios). Commit f851203.

3. **AXIOMS.md grounded.** Connected settling time to navigation requirements (moves, cost, laws). Candidate native law: C(d) = d + s*(d). Commit efdeb57.

4. **SVB-2 designed but not launched.** Fine-grained suffix resolution [0,1,2,3,4,6,8] to resolve d4's anomalous s1 peak. Three pre-registered hypotheses. ~128 min CPU — not launched due to battery concern. Config at experiments/config/svb_2.json. Commit b00367c.

5. **Visualization artifact published.** Settling time law, interactive charts with hero stats, heatmap, and data table.

## Current project state

**The settling time law is the first candidate native axiom.** It has no R^n analogue (all coordinates of a vector are equally accessible). The model stores deep information but needs recurrent processing time to access it.

**Open questions (for Codex evidence gate, credits return 2026-09-06):**

1. Are SVB-0+SVB-1 results evidence-gate clean?
2. Does settling time qualify as a native axiom candidate?
3. Strongest counter-explanation? (memorization, tokenizer artifact, etc.)
4. Which single model most efficiently tests universality?
5. Is the 11-bin response law a confound?
6. Should we formalize C(d) = d + s*(d) or wait for SVB-2?

## Next steps (priority order)

1. **Codex evidence gate** (2026-09-06) — agenda prepared in NOTEBOOK
2. **SVB-2** — config ready, launch when battery allows (~128 min CPU)
3. **Cross-model comparison** — same task on pure transformer vs pure SSM
4. **Variable count scaling** — 1-4 vars at depth 1
5. **Binding composition** — does f(g(x)) compose from f and g?
6. **Formalize settling time** — with Codex, as native axiom

## What's preserved

- All experiment records: STATE.md, NOTEBOOK.md, experiments/EXPERIMENTS.md, experiments/ledger.jsonl
- All results: experiments/results/svb_0/, experiments/results/svb_1/
- Theory: theory/AXIOMS.md (empirical grounding section at line 70)
- Config for next experiment: experiments/config/svb_2.json
- Visualization: artifact at claude.ai (settling time law)
- Memory: direction_native_latent_math_2026_08.md (updated)
- Prior work: legacy/ (unmodified, do not run or cite)

### Key constraint

Codex CLI credits exhausted until 2026-09-06. Design gates and evidence gates deferred. Theory formalization (settling time as axiom) blocked on Codex. CPU experiments allowed but sustained load risks hard shutdown (battery).

## Handoff 2026-09-01

## Handoff — 2026-09-01

### What happened this session

1. **EAC-1 PASS → STOP.** The from-scratch carrier (359K params, 6 states, 3 actions) passed all 7 causal gates across 3 seeds. Codex review determined it is architecturally tautological: the carrier IS the next-state embedding, host/donor share the same world, no action representation is transplanted. EAC/LAC line stopped. Commit 020ba04.

2. **Direction dialogue (3 Codex rounds).** Converged on testing KV command-slot transplant in frozen Qwen3-0.6B-Base as a bounded engineering falsification (not native math — Codex self-corrected in R2). Concrete task: three-item permutation. Budget: 4 launches, 2000 CPU forwards, 6 wall hours.

3. **Eligibility test: INELIGIBLE.** Qwen3-0.6B-Base scores 48% on three-item permutation (gate >=95%). Rotate left 13%, rotate right 34%, reverse 97%. Kill condition fires. Entire 4-launch program dead. Commit 9a27527.

4. **Codex R3: no next step.** "There is no concrete next experiment I can specify with confidence. The project needs user direction."

### Current project state

All experimental lines are stopped or killed:

- Phase 1: R^n tools closed (50 experiments)
- Phase 2: Observational ceiling in Qwen micro-world (18 experiments)
- Phase 3: EAC/LAC from-scratch carriers tautological
- Phase 4 attempt: Model can't do the eligibility task

The project is OPEN. Native math existence remains axiomatic. The experimental program is paused at a genuine fork point.

### The decision needed

Codex R3 framed it as:

> *Should Phase 5 pursue discovery inside a larger frozen pretrained model, or co-develop a modified real model whose latent space supports navigation — and what externally valuable task will define effectiveness against prompting, symbolic control, and KV caching?*

Codex leans toward co-development: accumulated holes suggest current frozen spaces may be structurally hostile to well-defined navigation. But this changes

the project from discovering native structure to constructing a next-generation latent space.

### What's preserved

- All experiment records: STATE.md, NOTEBOOK.md, experiments/EXPERIMENTS.md, experiments/ledger.jsonl
- Theory deposits: theory/AXIOMS.md (D1-D9, Theorems 1/4/7/8)
- Codex direction transcripts: scratchpad/codex_direction_r1.txt through r3.txt
- EAC-1 as positive control for what tautological gates look like
- Phase 2 findings (commitment bottleneck, non-naturality, fusion-fission distributed mechanism, QPC-1 hole result)
- Blackboard state: 742 entries on board 5df235ea

### Restart procedure

When a direction is chosen:

1. Read AGENTS.md (operating process)
2. Read STATE.md (canonical state)
3. Read NOTEBOOK.md (latest 2-3 entries)
4. bb_get_state on board 5df235ea (mission board)
5. Run Codex design gate for the new direction (2-3 rounds)
6. Write config, runner, preregistration
7. Execute

## Handoff 2026-08-30

## Latent-Space Reasoning — Phase 1 handoff (HISTORICAL)

> ***HISTORICAL DOCUMENT.** This handoff was written when the program was temporarily closed on 2026-08-31. **The program was REOPENED on 2026-08-31** because the closure was not authorized by the project owner. Native latent-space math existence is axiomatic. Phase 2 begins with genuinely non-R^n approaches. The Phase 1 record below is preserved as-is for provenance. Current state: `STATE.md`. Current direction: `README.md`.*

This is the front door for anyone — human or coding agent — arriving with no context. It tells you what the program was, why it closed, what it produced, and where the residue went. Audit-licensed scientific wording is quoted or linked to its source. The arc, repository map, and operating sections are navigation summaries and must not be cited as findings. `STATE.md` governs scientific claims.

### Mission and guiding question

**Program (2026-08-27 → 2026-08-31, CLOSED): the native mathematics of latent spaces.**
Embedding and latent spaces are not number systems. This program attempted to build their mathematics from axioms upward — what a latent space is, which relations and operations are meaningful — Euclid-style, rather than porting

$\mathbb{R}^n$ mathematics onto embedding vectors.

> *Mathematics was invented by inhabitants of a world to navigate it — counting, measuring, mapping, predicting — and its laws were shaped by what that world made necessary. Invert the dynamic: **take the latent space as the world.** Ask what a denizen of that world would have to invent to find its way — what counts as the same place, what a move is, what effort a move costs, what a map is, what regularities make prediction possible — and let that need decide which primitives and laws we build.*

## Why the program closed

Three converging findings, confirmed across 4 rounds of Codex direction dialogue (rounds 4–7) and a final portfolio review (round 8):

1. **The R^n trap.** Every empirical approach used R^n tools (PCA, Procrustes, cosine similarity) to study a space whose premise is that it isn't R^n. The program could not escape its own measurement apparatus.

2. **No new mathematics found.** All proposed native objects (separator languages, executable differences, cell complexes, internal port sufficiency) mapped to existing established mathematics (coalgebra, PSR, automata, causal abstraction, higher-dimensional automata). Across 50 audits, no construction established genuinely novel mathematical structure.

3. **Architectural impossibility (for current architectures).** The closing theoretical analysis (committed `dab8471`, `15ce061`) showed:
- **Transformers:** Growing KV-cache state is non-R^n but inaccessible from the fixed-d residual stream. The Robust Port-Compression Conjecture formalizes why: no fixed layer's newest-token residual realizes the full append-action process once prefix complexity exceeds d.
- **SSMs:** Fixed-dimensional state is accessible but described by standard spectral theory and semiseparable matrices — not new mathematics.
- **Neither yields genuinely new latent-space math.** A substrate that would require new math needs fixed-dimensional, non-linear-algebraic, compositional, accessible state — which no current architecture has.

4. **Terminal experiment.** PSQ-3α (task-trained LoRA, single-seed, 5000 steps) returned NO_INTERFACE (69.14% accuracy, gate ≥95%).

## Deposits and residue routing

### Theory (in this repo)

`theory/AXIOMS.md` carries an adopted foundation — future-response geometry (D1–D9, Theorems 1/4/7/8): identity as zero future-response distance, nonexpansive legal moves, surgeon-vs-denizen refinement, and the Robust Port-Compression Conjecture (unaudited closing deposit). Architectural comparison (transformer vs SSM) and speculative note on what state would require new mathematics appended as closing deposits.

### Five transferable insights

1. A model has many operational latent spaces — indexed by (actions, observations, horizon).
2. Information ≠ state: state has three gates (present → addressable → composable).
3. The right null is the system's cheapest native mechanism, not random features.

4. A quotient must be earned by a transport — held-out presentation ≠ quotient-level generalization.

5. Absence requires a collision witness (same carrier, different future), not a failed probe.

### Cross-project deposits (Codex R8 routing)

| Deposit | Target | What |
|---|---|---|
| Three state gates, transport-earned quotients, collision witnesses, cheapest-mechanism nulls | `moonshot-llm-genome` | Strengthens its three-gate mechanism contract; HANDLE constructive pivot enters there as a co-trained substrate, not here |
| Information-vs-causal-state distinction, action-conditioned carrier preservation | `neuro-ai-lab` | Deposit into pruning/circuit work; not a reopening |
| Portfolio index update | `_meta/INDEX.md` | LSR row updated from active to closed |

### HANDLE (constructive pivot)

HANDLE (Handle-Addressable Neural Dynamics with Lawful Execution) was identified as the constructive next step — build an architecture with explicit state commitments, then discover its mathematics. **HANDLE belongs in `moonshot-llm-genome`**, which already owns the contract it must satisfy (internal signature, causal intervention, reliability). It enters as a materially new co-trained substrate, not an inherited hidden-state license.

### The conjecture

The Robust Port-Compression Conjecture is preserved as an unaudited open deposit. It should not become a proof project here without first passing a bounded novelty audit that: (1) separates it from memory lower bounds and state-realization theory; (2) defines behavioral effective dimension non-circularly; (3) replaces exact collision with an approximate or discrete theorem. Its broad compression thesis is already close to Haris & Onak's linear KV-memory requirements result.

## One-screen program arc

| Line | Status | Binding provenance |
|---|---|---|
| Prior perturbation/diffusion program | Closed 2026-08-27; nested-arithmetic claims withdrawn after the benchmark was shown to measure termination under a token cap | `legacy/README.md`; `legacy/docs/CORRECTION_NESTED_ARITHMETIC_2026_08.md` |
| NLM-007 residual-dynamics line | Closed by terminal allocation rule, not by a scientific null | Audit #22; ledger `nlm007_closed_audit22`; `STATE.md` "NLM-007 — CLOSED" |
| Toy operational-quotient program | Ended; no learned artifact passed the complete exact reducer, and Round 37 found no architectural win | Audits #23–#26 plus the Round 37 audit |
| Frozen-model coordinate/interchange/state-bus/control-cost line | Stopped as an allocation pivot, not a scientific conclusion | Audits #27–#31 |
| One-write positive-control staircase | Exact constructions failed or localized instrument, extraction, actuator, or prompt/output-geometry constraints; no general memory/capacity conclusion | Audits #32–#36 |
| Constructed register substrate | Rung 0 is a qualified synthetic oracle-code selector; rung 1 is a qualified answer-supervised eight-symbol writer; neither establishes semantic writing, persistence, geometry, or pretrained-model structure | Audits #37–#38 |

| | | |
|---|---|---|
| Real-model bridge preflight | Noncausal feasibility PASS (audit #39 UPHOLD): explicit-legend state linearly decodable at the record span under held-out entities, two held-out templates and a disjoint balanced permutation bank; not a code-level or causal bridge | Audit #39 |
| Theory-first restart (2026-08-30) | D1–D9 adopted; Robust Port-Compression Conjecture formalized (unaudited); architectural comparison (transformer vs SSM) deposited | Audits #40–#50; theory/AXIOMS.md |
| PSQ-3α terminal experiment | NO_INTERFACE (69.14%, gate ≥95%); task-trained LoRA could not establish the interface | experiments/results/psq3_alpha/result.json |
| Direction rounds 4–8 | Program closed; archive + deposit recommended (1 >> 3 > 4 > 2) | Codex direction dialogue rounds |

## Do not repeat

Every exact recipe below is closed to rerun. The rows include construction failures, a measurement, qualified synthetic calibrations, and a noncausal preflight; those scientific statuses are not interchangeable. The right-hand column is a pointer to the binding licensed sentence and never-say list in `STATE.md`; it is not permission to paraphrase.

| Construction | Closure reason | Licensed/never-say authority |
|---|---|---|
| NLM-007 | Terminal allocation stop; Round 34b inconclusive | `STATE.md` NLM-007 block, audit #22 |
| Operational quotient v1/36b/36c/36d and presentation quotient | Toy program ended; exact certificates diagnostic-only; Round 37 no architectural win | `STATE.md` closed-toy blocks, audits #23–#26 / Round 37 |
| `coordinate_v1` | `UNINTERPRETABLE — INVALID POLARITY BASELINE` | `STATE.md` historical coordinate block |
| `coordinate_v2` | Killed at the predeclared baseline gate | `STATE.md` historical `coordinate_v2` block |
| `coordinate_v3` | Coordinate claim negative; narrow late lexical-control diagnostic only | Audit #27 block |
| `interchange_v1` | Locked raw-zero baseline failed; no swap arm ran | Audit #28 block |
| `interchange_v2` | Fixed single-anchor replacement construction failed | Audit #30 block |
| `state_bus_v1r1` | Fixed-construction fail; repeated supervised response controller, not autonomous state | Audit #29 block |
| `control_cost_v1` | Fixed actuator/solver/readout/budget construction failed; censored costs void broader laws | Audit #31 block |
| `onewrite_state_v1` | Killed pre-lock because the visible-fact instrument failed; no state hypothesis tested | Current statement |
| `onewrite_recall_v1` | Valid instrument, but the registered held-out channel failed | Audit #32 block |
| `onewrite_recall_rung1` | Training-item construction failed; failure initially unlocalized | Audit #33 block |
| `oracle_actuator_rung0` | Exact shared-J oracle actuator failed | Audit #34 block |
| `site_oracle_v1` | Balanced bounded eight-way control failed; exact slot/prompt recipe closed | Audit #35 block |
| `reachability_v1` | Measurement classified `NO SLOT-SPECIFIC GEOMETRY CONCLUSION` | Audit #36 block |
| Constructed register rungs 0–1 | Qualified synthetic calibrations; synthetic staircase stopped after audit #38 | Audits #37–#38 |

| | | |
|---|---|---|
| `register_bridge_preflight_v1` | No repair or rerun; use audit #39 | Audit #39 |
| PSQ-3α | NO_INTERFACE; task-trained LoRA terminal experiment | experiments/results/psq3_alpha/result.json |

## Durable findings from the frozen-model line

Verbatim from `docs/STRUCTURED_NEGATIVE_2026_08_29.md` ("Findings that survive audit"):

- "Under the current apparatus budget, this sequence of frozen residual-stream constructions is not yielding a native-mathematics artifact, so open-ended layer, task, and decision-rule repair stops here. This is an allocation pivot, not evidence that frozen pretrained residual streams lack usable native structure."
- `state_bus_v1r1` licensed "repeatedly maintained supervised response control with donor-verbalizer-specific lexical/semantic steering," not autonomous persistence, abstraction, general interchangeability, or native latent mathematics.
- `onewrite_recall_v1` closes "the fixed model/layer/source-state/16-dimensional encoder/injector/norm-cap/slot/objective/400-step/prompt construction—not one-write memory, persistence, block-12 capacity, or persistent state in real models generally."
- The strongest unified explanation is local and plural: several frozen-model effects are parsimoniously explained by cue-redundant lexical-semantic response geometry rather than persistent state.

*The sequence did not show that the block-12 slot is too low-dimensional to carry state; it showed that this exact frozen-model interface never converted weak, presentation-bound source and response geometry into balanced, content-specific causal control, even though the slot has a coherent several-mode local effect on the registered output logits.*

## Repository map

- `README.md`: public front door (updated to reflect closure).
- `docs/HANDOFFS.md` (this file): closure handoff and historical record.
- `STATE.md`: canonical scientific wording and never-say lists; the "Current statement" at the top governs.
- `docs/STRUCTURED_NEGATIVE_2026_08_29.md`: the audited two-day synthesis of the frozen-model line.
- `theory/AXIOMS.md`: adopted foundation (D1–D9, theorems, conjecture, architectural comparison).
- `experiments/ledger.jsonl`: append-only provenance (one JSON object per line).
- `experiments/EXPERIMENTS.md`: detailed experiment record.
- `NOTEBOOK.md`: reverse-chronological dialogue and audit record.
- `experiments/config/*.json`: immutable contracts for completed runs.
- `experiments/results/`: result JSONs and small checkpoints; the ledger row's `data_ref` is authoritative.
- `legacy/`: the closed previous program (2026-08-27), not active.
- Local-only (git-ignored; absent from a fresh clone): `AGENTS.md`, `.codex_*`, `.blackboard/`, run logs.

## Newcomer traps

- Raw status strings are not final scientific claims. Audit wording governs.
- `state_bus_v1r1`'s displayed status omits one registered failure; use audit #29.
- The oracle-actuator result's "two codes worked" interpretation was corrected: code 0 reproduced the cue prior.
- `reachability_v1` does not establish two or three reachable dimensions.
- The tracked navigator `smoke_result.json` is not the 2,000-step smoke cited in `STATE.md`.
- `legacy/` is historical; its older NEXT/queue language is not authorization.
- Hash-bearing completed configs and runners are evidence; editing them destroys reproducibility.
- ~~This program is CLOSED.~~ **REOPENED 2026-08-31.** Phase 1 experiments below are closed results; Phase 2 uses non-R^n approaches. Do not reopen Phase 1's R^n-based repair ladders or measurement sweeps.

--- SOURCE FILE: docs/STRUCTURED_NEGATIVE_2026_08_29.md ---

<!-- Structured negative write-up. Drafted by the direction session (round 23) from audit-adopted wording in STATE.md and the ledger; reachability_v1 wording revised verbatim from audit #36. No new claims. Every construction's licensed sentence and never-say list is in STATE.md; the append-only record is experiments/ledger.jsonl. -->

# Structured Negative: What Two Days of Audited Latent-Space Experiments Localized

## Abstract

Across 2026-08-29–30, the program moved from toy certification to causal intervention in a real model and ended with a structured negative, not a no-go theorem. The Rounds 36–37 toy quotient program closed because no learned artifact passed the complete exact reducer, only the oracle fixture did, and the carrier comparison showed no architectural win; its durable lesson was that exact certificates are diagnostics for learned continuous systems, not verdicts, and toy results do not establish properties of real residual streams. The frozen-residual line—`coordinate_v1–v3`, `interchange_v1–v2`, `state_bus_v1r1`, and `control_cost_v1`—encountered invalid instruments, late lexical steering, a fixed-site null, a repeatedly injected supervised controller, and a failed fixed control-cost construction. It therefore stopped as an allocation pivot rather than a scientific conclusion. The positive-control staircase then localized the one-write failure: `onewrite_recall_v1` failed held-out recall on a valid direct-copy instrument; rung 1 failed proximal control on training entities; source localization found weak tag information at the generic source anchor; the oracle-code actuator failed balanced eight-way control even without an encoder; the site oracle found construction-bound HESK/VORN sensitivity but not a balanced channel; and `reachability_v1` found no slot-specific geometry relative to position and prompt controls. No native latent mathematics or transferable causal state was demonstrated, but the sequence produced concrete requirements that a future substrate must satisfy before stronger claims are tested.

## Findings that survive audit

- “Under the current apparatus budget, this sequence of frozen residual-stream constructions is not yielding a native-mathematics artifact, so open-ended layer, task, and decision-rule repair stops here. This is an allocation pivot, not evidence that frozen pretrained residual streams lack usable native structure.”
- `state_bus_v1r1` licensed “repeatedly maintained supervised response control with donor-verbalizer-specific lexical/semantic steering,” not autonomous persistence, abstraction, general interchangeability, or native latent mathematics.
- `onewrite_recall_v1` closes “the fixed model/layer/source-state/16-dimensional encoder/injector/norm-cap/slot/objective/400-step/prompt construction—not one-write memory, persistence, block-12 capacity, or persistent state in real models generally.”
- For the rung-0/site-oracle pair: “At this exact site and prompt, finite strict-choice response is strongly tag- and context-dependent. Removing the learned shared J does not remove the concentration of effects, so J optimization was not its sole source; nevertheless, the concentration remains inseparable from baseline logit gaps, cross-name gradient averaging, local-to-finite extrapolation, the fixed norm, and the first-token greedy readout.” `reachability_v1` (audit #36, verbatim): `reachability_v1` is a preregistered measurement with classification `NO SLOT-SPECIFIC GEOMETRY CONCLUSION`: at the fixed block-12 final `Internal record:` slot in frozen Qwen3-1.7B-Base, 42–43 tokenizer-position steps before the queried logits, the mean over 24 training names of the \(0.25\|h\|\)-scaled centered Jacobian of eight tag first-token logits had top-mode energy 0.638 (name-bootstrap 95% CI 0.624–0.652), participation effective rank 2.279 (2.197–2.362), \(\sigma_2/\sigma_1=0.450\), and \(\sigma_3/\sigma_1=0.389\); a read-only audit recomputation found typical per-name geometry of similar width and 0.895 mean-energy coherence, so averaging did not create the result, while the eight preselected instruction-token position controls spanned top energies 0.579–0.731 and effective ranks 1.809–2.664 and all four fixed displayed-tag-order permutations produced broader spectra; at one finite dose the top three shared slot directions had median predicted-versus-realized centered-logit cosines 0.995, 0.944, and 0.995 and substantial secondary-mode responses, but sign-dependent magnitude and decoded-boundary asymmetries remained, so the result licenses a coherent several-mode local response under this exact prompt, vocabulary, site, layer, and dose, not a slot-specific dimension, a hard reachability limit, equivalence to generic positions, an explanation of the earlier two-tag pattern, or evidence about memory capacity.

The strongest unified explanation is correspondingly local and plural. Several frozen-model effects are parsimoniously explained by cue-redundant lexical-semantic response geometry rather than persistent state. Small base models could not support the more demanding rule-application instruments, although direct visible recall was valid. The chosen generic source anchor carried only weak tag information. Finally, the actuator’s apparent anisotropy was construction-bound and was not isolated from prompt, label-order, baseline-gap, or output-boundary geometry. These are four constraints, not one universal latent-space hole.

## The central sentence (audit #36)

> *The sequence did not show that the block-12 slot is too low-dimensional to carry state; it showed that this exact frozen-model interface never converted weak, presentation-bound source and response geometry into balanced, content-specific causal control, even though the slot has a coherent several-mode local effect on the registered output logits.*

## Methodological result and cost

The positive-control staircase was the decisive process improvement. It prevented held-out names, unseen wording, and long delays from concealing a proximal failure, and it separated instrument validity, source extraction, actuation, propagation, and readout instead of naming whichever downstream component was most convenient after a failure.

Three other governance rules mattered:

- Exact certificates remained diagnostics; primary judgments used tolerances, effect sizes, controls, and seed spread.
- One fresh audit governed each result and corrected overclaims without spawning sentence-by-sentence repair runs.
- Position, prompt, visible-copy, cue, counterfactual, random, and zero-hook controls were treated as parts of the scientific object rather than post-hoc explanations.

The cost was high. With the single audit attached to `reachability_v1`, the declared closeout accounting is 15 measurement or governance rounds to five artifact-building rounds, or 3.0:1. That exceeds the warning threshold. The correct response is this consolidation and closure, not another site, layer, model-size, or actuator repair.

## Requirements for a future substrate

A successor must satisfy these requirements in order:

1. Its behavioral readout must be valid on the unmodified base: visible information must produce the required behavior with adequate completion, while the cue-only arm must not.

2. The chosen source representation must demonstrably contain the fact under held-out source wording before an encoder is credited with extracting it.

3. A fixed oracle code must pass bounded, proximal behavioral control against wrong-code, random-code, cue, and zero-hook arms before source encoding is introduced.

4. Exactly one difficulty—delay, names, wording, or consequence family—may change at each staircase rung.

5. Primary evidence must be actual decoded behavior or another independently valid behavioral outcome, not likelihood uplift alone.

6. Site-specific geometry requires matched position and prompt/output controls. Neither an effective rank nor favored decoded labels may be called intrinsic to a site when generic positions or tag-order permutations reproduce the effect.

7. Norms, cap activation, causal distance, and pre/post intervention telemetry must be recorded so optimization, dose, site reachability, and retrieval are not conflated.

## What remains open

The mission still asks whether a denizen of a real latent space has stable notions of place, move, effort, composition, prediction, and causal state. These experiments do not determine whether such structure is distributed across positions or trajectories, exists at another layer or site, appears in another model family or scale, requires a context-conditioned actuator, or must be introduced by training. The synthetic navigator also remains an unrun calibration control, not evidence about pretrained language models.

Never say:

- Frozen pretrained residual streams lack usable native structure or native mathematics.
- Persistent state must be built rather than discovered.
- The toy and real-model programs exposed the same latent-space hole.
- Block 12 cannot support memory, reachability, or an eight-way channel.
- HESK and VORN define two reachable dimensions or an intrinsic subspace.
- The intervention wrote a fact that was later forgotten.
- The state bus demonstrated persistence, abstraction, or general interchangeability.
- `coordinate_v3` demonstrated a grammatical coordinate.
- `reachability_v1` established a low-dimensional slot or a general early-position geometry.
- The slot is equivalent to, or indistinguishable from, generic early positions; the two-tag pattern was proved to be boundary geometry; the finite-dose response is linear at 0.25‖h‖ (only directional agreement along the tested modes at one amplitude was shown).
- More steps, another site, a larger model, or a different actuator would either succeed or fail.

**README status:** Across two days of audited CPU experiments, no tested construction established a transferable causal state or native latent mathematics in a real model; the durable result is a localized set of instrument-validity, source-extraction, actuator, and

prompt/output-geometry constraints that any future substrate must satisfy.

# Vol 10 - State Archive: All Closed Lines (NLM rounds, toy program, frozen-residual lane)

*Verbatim inclusion of the repository's canonical document(s). Headers below belong to the source documents.*

--- SOURCE FILE: docs/STATE_ARCHIVE_closed_lines.md ---

# STATE archive — closed lines and prior campaigns, moved verbatim from STATE.md on 2026-09-05 (sections from "Prior campaign: Continuation-Refinement Calculus" downward, original order).

## Prior campaign: Continuation-Refinement Calculus (2026-09-04)

**Pivot from SVB (Codex-directed, 2026-09-04):** All SVB-campaign experiments
produced structured negatives (congruence, S3 composition, noncommutativity,
curvature). Root cause: scalar logit projections (the R^n trap). New direction:
study which future operations distinguish which states, not where states lie
in a vector space. Primary objects: separating languages Sep(x,y), refinement
tower Q_0 ← Q_1 ← ..., Brzozowski derivatives under actions. Theory document:
theory/CONTINUATION_REFINEMENT.md. One bounded CPU test on Qwen3, decisive.

---

## Prior campaign: Intensional Descent Criterion (2026-09-03 — 2026-09-04, CLOSED)

**Central claim under test:** Pretrained transformers implement proof-relevant
causal semantics — they compress execution histories into equality-witness
classes that are strictly finer than denotational state, strictly coarser than
token history, compositional across operations, and causally controlling later
inference.

**Formal framework:** theory/closed/INTENSIONAL_DESCENT.md (D10-D15, extending D1-D7).
Key structure: P →J→ I →q→ D factorization. Model's action factors through
intensional quotient I but NOT through extensional denotation D.

**Algebraic structure (Codex-derived):** I = P/≡_M is a **transformation monoid**
(not a group) acting on behavioral places, isomorphic to im(α) □ End(Q_M).
Graded by denotation via q: I → im(E). The identity fiber EqWit = ker(E)/≡_M
is a submonoid. If the leakage observable satisfies a separable depth-scaling law,
χ: EqWit → (R≥0, ×) is a **multiplicative character** of the monoid.

**Operator status (2026-09-04):** K_A as 3×3 stochastic matrix is DEAD.
The actual operator is a surface-specific, depth-invariant logit bias on
shadow probability: δ_L(s) constant across d2-d4 (CV=0.036 for ASSERT).
Quotient closure holds for single suffixes (100% ASSERT). BUT congruence
test FAILS: behavioral equivalence is NOT preserved under composition with
semantically heavy suffixes (ratio 2.6-13.2x). Text features predict
delta_L at R2=0.88.

**Curvature line (2026-09-04, CLOSED — Codex-adjudicated):** Confound-killing

control round completed: isochronous position-matched design (768 calls, 6 templates, 2 shadow digits, 2 padding families). G0-G3 PASS, G4-G6 FAIL. G5: κ=−0.542 nat, 12/12 block averages negative, CI [−0.698, −0.362] — but pad_diff_ok FAILS (0.329 > 0.10 tolerance). 93/96 individual cells negative, 3 PAD_BARE cells positive. Position-gain null (G4) failed to transport across template families. Codex verdict: Option (b) — real but qualified behavioral interaction, NOT confirmed intrinsic curvature. Line CLOSED per one-round authorization. Transferable residue: exact position matching did not produce representative-invariant magnitude; scalar position-gain law fails transport; response law is presentation-conditioned. Key observation: "This line is not working as a route to native latent-space mathematics: it remains scalar logit finite differences and OLS — the R^n trap."

**Distance from central claim: 0.** This IS the native math claim.

**Gate progression:**

 Gate 1 (Semantic Descent): CONFIRMED — ASSERT L=0.032, MISLEADING_ASSERT L=0.124, diff=+0.092 (t=21.23). Holdout: +0.121. Depth-scaling ~4x ratio across all depths (3.7, 3.9, 4.0). Variable-mention confound identified.

 Gate 1b (Confound Control): COMPLETE.
- 2×2 ANOVA: CONTENT DOMINATES at 6.3x (content +0.0915 vs var-mention +0.0145). Per depth: d2=32x, d3=6x, d4=4.9x. Replicates on holdout.
- Lumpability (F8): STRONG (R2 0.79–0.98 all roles). The (C,L,R) simplex projection is approximately lumpable — K_u is a well-defined operator on the simplex, not just a fitted summary. BOUNDARY (0.98) and MISLEADING_ASSERT (0.96) near-perfect.
- Multiplicative character: Step 1 PASS (cellwise ratio CV=0.214). Step 3: within-class CV 0.33–0.51 — a_u is NOT class-invariant, it is surface-specific. Step 4: K_a vs logit-bias cross-fit INCONCLUSIVE (no holdout data).
- R-preservation: ASSERT dR=−0.0066, MISLEADING dR=+0.0028 (both small, tentatively favoring K_a over logit-bias).
- Surface equivalence: Class A has 1 cross-role pair at eps_eq=0.01 (ASSERT:"State unchanged" ↔ ASSERT_VAR:"{var} is unchanged", max TV=0.009). Class M has ZERO qualifying pairs (best=0.022). Between-class p5=0.024.
- F6 Baseline: MARGINAL (+0.0064 TV over cheap features).

 Gate 2 v1 (Noncommutativity, same-role controls): COMPLETE — RECENCY_DOMINATED. Cross-role TV median=0.081 < same-role max=0.130. Same-role ASSERT nearly commutes (TV=0.006) but same-role MISLEADING is highly noncommutative (TV=0.097) due to extreme a_u variation (0.50 vs 1.44). Cross-role signal real but cannot be distinguished from MISLEADING internal variation.
Codex correction: same-role controls are the wrong null model. Need filler-based design with token-length-matched neutral fillers to absorb additive position effects.

 Gate 2 v2 (Noncommutativity, filler-based): CLOSED — POSITION_WITH_NONLINEAR_GAIN. 216 calls, 24 contexts, deterministic. Gate 1 (direct order) PASSES strongly: median TV(AM,MA) = 0.068 > 0.01. Gate 2 (excess interaction) FAILS after multi-filler robustness test: residual order contrast exists (medians 0.040–0.089 across 3 filler pairs, cross-pair corr 0.69–0.92) but scalar gain fit absorbs

it entirely (post-gain medians 0.003–0.009 < 0.01, 0/24 contexts above threshold for pair 2). The order effect direction is positional; magnitude is context-dependent. Nonlinear position gain is confirmed as the correct explanation.

- Gate 3 (Causal Relay-State Composition): Codex-designed decisive experiment. Compile operations into relay states at declared layer-position cut, mask original tokens, predict unseen compositions from atomic table, transplant relay states causally. BLOCKED on Gate 2, requires GPU.

**Codex theory verdict (Architecture Theorist, 2026-09-04):**
"Noncommutativity is cheap; stable equations are expensive." The transformation monoid exists for any sequential transducer. The native prize is model-discovered, representative-independent algebra with causal realization. Gate 2 noncommutativity is necessary but narrow — it proves an obstruction to commutative factorizations, NOT dimension bounds, compression, proof-relevance, or topology. The full native math claim requires the causal relay-state experiment (Gate 3).

**Logit-bias rival (Codex 2026-09-04 follow-up):** Content dominance alone does NOT defeat the rival — content-specific δ_u is compatible. Analyzer Step 4 was tautological (fixed with cross-fitting). R-preservation is the key discriminator: K_a predicts ΔR=0, logit-bias predicts |ΔR|≈0.026. Noncommutativity is the strongest overall discriminator — defeats K_a too.

**Active confound:** MISLEADING_ASSERT surfaces mention the variable name (3/4 do), while ASSERT surfaces don't. The +0.092 L difference could be partly a variable-mention effect. Gate 1b adds ASSERT_VAR (true assertions + var mention) and MISLEADING_ASSERT_NOVAR (misleading assertions - var mention) to disentangle.

**Kill conditions:** F0-F9 in theory/closed/INTENSIONAL_DESCENT.md. F6 (baseline) requires nested ladder M_state < M_cheap < M_cheap+role per Codex.

**Prior evidence:** SVB suffix ablation (a~0.38 for ASSERT vs b~0.13 reverse for REWRITE) supports IDC-N (extensional non-descent). Gate 1 partially supports IDC-C (compression) pending confound resolution.

---

## Prior campaigns (closed)

## Frozen-residual measurement lane (2026-09-01, CLOSED)

**The entire frozen-residual measurement lane is CLOSED.** Terminal diagnostic (Codex round 10) showed the OCI/RAC composition is ordinary logit addition through a linear unembedding — decoder competition, not native structure. Gate I: logit-additive null explains 99.1% of the composition effect (sqrt(JSD) = 0.0001, 12/12 top-1 match). Gate F: NO_INTERFACE — no template pair has baseline sqrt(JSD) < 0.15; the model has no template-invariant response fiber.

**Closure characterization:** Everything the OCI/RAC line found reduces to:
(1) factored encoding in hidden states (PCA/linear algebra, R^n scaffolding);
(2) logit-additive composition through the linear unembedding (decoder competition);
(3) template-dependent responses (no fiber invariance). None are native math.

**FBA-0 (Codex rounds 11-21, R21 GO → CAMPAIGN COMPLETE: FAIL).**

Distance from claim: 1 (engineered-factorization control).
Architecture: two-branch 16/16 independently-updated recurrent bottleneck (32 dims total).
Six-way comparison: FBA (33,664), flat GRU (40K), flat-matched (33K), asymmetric split (24/8, 34,688), modular (4×8, 34,688), flat bottleneck (37,760).
Environment: Z/8 × Z/4 POMDP, 16 opaque actions, T=3, 85/15 confusion matrix.
Oracle: historyless ~72-73%, recurrent ~95-96%. Split: 21/3/8 response classes.
Kill gates: K4/K6/K7a/K7b + paired effects. Theory: theory/closed/FBA_BRIDGE.md.

**Campaign results (3 seeds, 2000 epochs, 20.1 minutes total):**

- Seed 42: FBA=0.847, asym=0.924, K7b FAIL (cross=0.630 < null=0.722)
- Seed 137: FBA=0.915, asym=0.828, K7b PASS (cross=0.884, CI=[0.846,0.923])
- Seed 2026: FBA=0.897, asym=0.924, K7b FAIL (cross=0.414 < null=0.722)
- Joint predicate: 0/3 seeds pass. **OVERALL FAIL.**

**Key findings:** (1) K7b interchange is seed-dependent — passes brilliantly for seed 137, fails for 42 and 2026. (2) Asymmetric 24/8 wins 2/3 seeds on test accuracy; width allocation dominates product factorization. (3) Flat bottleneck matches or beats FBA (seed 2026: 0.926 vs 0.897). (4) Pre-registered gates (20pp, 15pp) too aggressive for actual 4-9pp effects. (5) Wrong-channel controls pass consistently (0.93-0.98).

**Transferable residue (Codex Round 1 HANDLE-1):** Separate recurrent write paths are insufficient for autonomous causal handles. Same-factor preservation is insufficient for composition. Width should track factor complexity. A handle claim requires off-episode intervention with future-response validation.

**HANDLE-mu Rung 1 (V1 FAIL, V2 campaign running seed 42).**
Distance-1 constructive control. Non-visual key-lock grid (7x7, partial visibility r=2). 5 causal handles (2 keys, 2 locks, goal; agent is shared context, excluded from handle graph). Behaviorally defined: i→_c j iff paired interventions differing only in i change j's next-response distribution. Dense typed slots (6x32, all-pairs messaging) as primary arm; learned-sparse and flat GRU as controls. Training: next-obs + next-event prediction only, no swap/graph supervision. Seven pre-registered gates.
Spec: theory/closed/HANDLE_MU.md. Runner: experiments/run_handle_mu.py.

**V1: FAIL (world too transparent, recurrent lift -0.003). V2: campaign in progress.**

**V2 seed 42 (R5 code, 64 levels, 128 trajs/level, 40 epochs, 3211s): ELIGIBILITY FAIL.**

| Model | Params | Val Loss | Event F1 | Status F1 |
|---|---|---|---|---|
| Dense | 19511 | 0.093 | 0.961 | 0.993 |
| Sparse | 19511 | 0.115 | 0.955 | 0.990 |
| CB w192 | 19079 | 0.189 | 0.966 | 0.959 |
| Historyless | 13175 | 0.168 | 0.862 | 0.932 |
| FlatGRU | 18574 | 0.455 | 0.845 | 0.877 |
| Oracle | — | — | 1.000 | 1.000 |

Gate outcomes (seed 42, OLD evaluator — 3 bugs present):

- Eligibility: **FAIL** (recurrent lift 0.098 < 0.10, CB status gap 0.034 > 0.03)
- Causal consumption: FAIL (0.127, buggy patch boundary + insufficient pair budget)
- Shielding: PASS (0.061)
- Timing: FAIL (miss_rate=1.0, aggregation bug — actual 46.3%)

**Evaluator repair (5 fixes, 2f9d3ce):**

1. Patch boundary: transplant before forward_step (was after — spec violation)
2. Timing aggregation: timing_misses/contacts propagated (was dropped → 1.0)
3. Cross-seed adjudication: numerical median of gate metrics (was boolean)
4. Pair budget: 512→1024 (204/handle, above 128 floor)
5. NumPy bool serialization: _NumpyEncoder (was default=str → "True"/"False")

**Post-Codex evaluator repair (13 fixes total, 4679c17):**
Codex NO-GO verdict on original 5 fixes identified 7 additional issues. All addressed:

6. Pair RNG uses data_seed (not model_seed) per shared-manifest rule (c0bb1fe)
7. Contact step recorded in causal_consumption entries (c0bb1fe)
8. Registered cell filter: only {(0,2),(0,3),(1,2),(1,3)} scored (c0bb1fe)
9. Contact delay filter: Rung 1 = τ≤1 only (c0bb1fe)
10. Intervention eval bank: 512 trajs/level for pair support (c0bb1fe)
11. Pair search: 500 attempts, budget 2560 (c0bb1fe)
12. Recurrent lift CI: level-clustered bootstrap, gate requires LB > 0 (5e631a6)
13. Cell-macro causal consumption CI: bootstrap matches spec estimand (5e631a6)
14. Shielding level clustering: proper level IDs instead of fake clusters (5e631a6)
15. Per-seed JSON rewrite after cross-seed adjustments (5e631a6)
16. Patch integrity gate: non-target slot TV with bootstrap CI (4679c17)
17. Identity permutation partition: 576/144 train/test split (4679c17)
18. n_pairs_total counts actual pairs, not causal contact rows (4679c17)

Smoke-tested: 4 successful runs, exit 0, all gates display correctly.

**Remaining:** Patch boundary spec amendment — Codex review in progress (was running when session ended). The current order (patch→obs+act→predict) is semantically correct for V2 latent keys because observation is broadcast and key state is exclusively in hidden memory, but spec says observe→patch→act→predict.

**Campaign status: FROZEN (2026-09-02).** Seed 42 ran under old evaluator (eligibility FAIL, lift 9.84pp < 10pp). Seed 137 ran under corrected evaluator but produced no result JSON (exit 0, ~21K CPU seconds, stdout buffering failure). Seed 2026 cancelled. Three independent Codex reviews (architecture review, process reflection, estimand mismatch analysis) converge: HANDLE-mu is calibration (distance-1), not the artifact. Infrastructure drift at 6:1 exceeds 5:1 halt threshold. No V3, no further evaluator amendments. Valuable residue: response-defined identity, shielding, timing, causal consumption, and composition gates.

**Codex V2 design gate (2026-09-01): conditional no-go, 7 blocking repairs.** Repairs implemented and committed (97dad28): event code fix, V2 oracle/intervention/counterfactual propagation, output path separation, policy randomization (first-key + lock order), blind goal probe, post-identification preflight with history ceiling, ControlB width ladder.

**HANDLE-mu V2 preflight PASSES (2026-09-01, V1 contract: canonical < 0.75).**
Post-identification analysis: canonical ceiling 0.6807 (< 0.75, V1 contract PASS), raw ceiling 0.7656 (diagnostic, exact model interface), hist ceiling 1.0000 (> 0.99). Memory gap: 31.9pp (canonical), 23.4pp (raw). All 4 cells balanced (~170 each). Goal bank healthy. Coverage 100%.

**Evidence gate: 4 Codex rounds pre-campaign + 2 post-seed-42 reviews.**
Pre-campaign fixes (all committed, f7a116d): goal_ok, bijection filter, ControlB F1

qualification + gate leak + cross-seed propagation, smoke/full separation, numerical median adjudicator, pair-support gates (>=64 pairs, >=16 levels), experiment-wide gate adjudication. Post-seed-42 structural review (3 bugs + pair budget) → 5 fixes (2f9d3ce, db2df73). Post-fix Codex correctness review: NO-GO, 7 additional issues → 8 more fixes (c0bb1fe, 5e631a6, 4679c17). Total: 18 evaluator fixes across 6 commits. 4 smoke tests passed. Patch boundary spec amendment pending Codex decision.
Spec: theory/closed/HANDLE_MU_V2.md.

Prior V1 rung 1 results: experiments/results/handle_mu/seed_42_rung_1.json.
V2 results: experiments/results/handle_mu/v2_*.json.

### PFC-0: Path-Fiber Calculus v1 (2026-09-02, TASK_POPULATION_VOID)

Distance-from-claim: **2** (Codex evidence gate correction) — K is a researcher-imposed 3×3 stochastic matrix acting on a 3-token softmax simplex; its composition is ordinary matrix multiplication. This is imported finite-dimensional probability algebra, not native latent-space math under the R^n standard.
Spec: Codex R3 lock (session 4). Runner: experiments/run_path_fiber_v1.py.
Config: experiments/config/path_fiber_v1.json.

**Design:** Four-corner path square (p00, pL, pR, pLR) with washout tail on Finch-3B entity-location task. 9 roots × 3 panels × 6 paths × 2 queries = 324 specs. Cross-fitted stochastic transports K_L, K_R learned from 3 corners on train roots, predict pLR on held-out roots. 7 baselines: parser, last-1, last-2, multiset, discounted history, primitive composition (Adam 3000 steps), causal 1-NN.

**Verdict: TASK_POPULATION_VOID**

| Gate | Value | Threshold | Result |
|---|---|---|---|
| Washed accuracy | 0.7917 | ≥0.95 | FAIL |
| Raw accuracy | 0.7222 | ≥0.95 | FAIL |
| Replay max TV | 3.1e-6 | ≤0.0001 | PASS |
| PFC coverage | 1.0000 | =1.00 | PASS |
| PFC mean TV | 0.0381 | ≤0.10 | PASS |
| PFC coherence mean | 0.0018 | ≤0.03 | PASS |
| PFC coherence p90 | 0.0027 | ≤0.08 | PASS |
| Raw defect mean | 0.0356 | ≥0.05 | FAIL |
| Wash defect mean | 0.0298 | ≥0.05 | FAIL |
| PFC advantage | -0.0187 | ≥0.02 | FAIL |

**Baselines (mean TV, lower=better):**

| Method | Mean TV |
|---|---|
| parser | 0.0194 |
| discounted | 0.0236 |
| last_1 / last_2 | 0.0248 |
| multiset | 0.0259 |
| primitive | 0.0312 |
| **PFC** | **0.0381** |
| causal_knn | 0.0440 |

PFC loses to every baseline except causal kNN (advantage +0.006, CI crosses zero).
All advantages have CIs entirely below zero except causal kNN.

**Diagnosis (Codex evidence gate corrected):** (1) Competence failure is garden-specific, not sequence-length: every failing arm targets garden (raw KG_O garden accuracy 0.000, washed OK_G garden 0.222); kitchen and office targets are 1.000. "Four actions exceed capacity" is unsupported; the issue is answer-token/location/prompt calibration. (2) "Washout erases the signal" is unsupported: raw-to-washed defect decrease is only 0.006 TV (CI [−0.0002, 0.0115]); one panel (OK_G) increases defect under washout. At most possible attenuation, not erasure. (3) Composed transport adds error vs identity: identity (predict pLR=p00) gives TV 0.0298, beating PFC 0.0381; root-paired identity-minus-PFC = −0.008, CI [−0.015, −0.002]. Single-edge K improves over identity by ~0.006 TV, but composition destroys the gain. Panel-additive residual (0.0197) beats K (0.0239).
(4) PFC coverage 1.0 only means SLSQP converged; coherence 0.002 says two near-identity matrices nearly commute — neither demonstrates latent structure.

Runner: experiments/run_path_fiber_v1.py. Results: experiments/results/path_fiber_v1/.

### PMO-0R: Path-Memory Observability Revised (2026-09-02, TASK_POPULATION_VOID)

Distance-from-claim: **1** — bounded continuation-distinguishability witness.
Spec: theory/closed/PMO_0R.md (Codex R1+R2 locked). Runner: experiments/run_pmo_0r.py.
Config: experiments/config/pmo_0r.json.

**Design (correcting PFC-0 defects):** Asymmetric endpoints (entities end at different locations), 4-bin response law {kitchen, garden, office, OTHER} with no renormalization, suffix injection via saved recurrent states, competence staircase, κ (commutation defect) + ι (entity interaction) dual observables, 9-method cross-fitted null ladder, two-band witness gates (registered 0.020/0.005, strong 0.050/0.020).

**Verdict: TASK_POPULATION_VOID** — direct fact competence failed (0/36, 0% accuracy).

| Gate | Value | Threshold | Result |
|---|---|---|---|
| Direct fact accuracy | 0.000 | ≥0.95 | FAIL |
| Relaxed accuracy (3-loc argmax) | 0.556 | — | diagnostic |
| P(OTHER) mean | ~0.65 | — | diagnostic |
| Model calls | 36 | — | — |
| Elapsed | 45.8s | <90 min | — |

**Root cause:** Finch-3B puts ~65% probability on continuation tokens ("answer", "question") rather than location tokens. The correct location IS typically the highest among the 3 location tokens (kitchen 23.9% vs garden 6.1%), but cannot beat P(OTHER)=65.1% as the competence gate requires. Even with relaxed competence (argmax among locations only), accuracy is only 55.6% due to strong kitchen bias (model picks kitchen even when correct answer is garden/office).

**Key finding:** PFC-0's 3-logit renormalization was hiding this fundamental model limitation. After renormalization, kitchen 68.5% looked like clear discrimination; the raw model barely distinguishes locations. Codex was correct to flag renormalization as a defect — it was also masking incompetence.

**Closure:** This response interface (4-bin + explicit-choice template) on Finch-3B is unsuitable. Per spec, competence failure closes the interface, not H_PMO or path memory as a concept. Entity discrimination (TV=0.43) and

bit-exact state replay remain confirmed.

Results: experiments/results/pmo_0r/result.json.

### RCQ-0: Real Causal Quotient on Finch-3B (2026-09-02, CLOSED — administrative/protocol)

Distance-from-claim: **0** — the quotient and action law ARE the native math.

Spec: theory/closed/REAL_CAUSAL_QUOTIENT.md. Runner: experiments/run_rcq0.py.

Config: experiments/config/rcq0_v1.json.

**Substrate (confirmed):** RWKV/v6-Finch-3B-HF. Entity discrimination TV=0.43 (PASS, gate >0.10). State replay TV=0.000000 (bit-exact). State injection: entity swap confirmed (TV=0.41/0.46). RWKV-4 models at ALL sizes FAIL entity discrimination (track location dominance, not entity-specific state). Entity discrimination emerges between 1.6B and 3B in RWKV-6 architecture.

**Task:** 2 entities (Avery, Blake) × 3 locations (kitchen, garden, office) = 9 joint states. 6 macro-actions. 2 probes. Teacher-forced log-likelihood scoring over 3 location tokens.

**Key finding: path dependence.** The model's recurrent state depends not just on the abstract entity configuration but on HOW it was described. Within-state word-order TV ranges from 0.0004 (symmetric states) to 0.2948 (office states). Median within-state TV = 0.09. This means the model genuinely distinguishes "Avery is in the kitchen. Blake is in the garden." from "Blake is in the garden. Avery is in the kitchen." — they are different behavioral states.

**9-state quotient: structural but non-compositional.**

- Ground-truth 9-state assignment (4 phrasings/state, 2 con + 2 held): within-class TV mean=0.12, max=0.33.
- Transition consistency: 0.86 (different phrasings of same state transition to different target classes 14% of the time).
- Composition top-1: 0.51 (4.6× chance, real signal but far from 0.90 gate).
- Self-composition (1 phrasing, no held-out): 0.65.
- Substitution: same-class TV=0.07 PASS, cross-class TV=0.36 PASS.
- Parser null: TV=0.19. Quotient composition TV=0.24. **No predictive surplus over text parser.**

**Diagnosis:** Post-action distributions differ from direct-statement distributions for the same entity configuration (path dependence TV ~0.25). The nearest-centroid lookup maps post-action states to wrong classes when path-dependent shift exceeds between-class gap. The 9-state model is too coarse for the model's actual behavioral state space.

**Affine behavioral dynamics (diagnostic, not native math):** Single-action affine fit TV=0.08. Two-action composition affine TV=0.21. Parser one-hot baseline TV=0.83 (unfair; fair parser-centroid comparison ~0.19 from RCQ). Codex ruling: affine fit is R^n diagnostic, not native math. It shows the dynamics have structure but the structure is an imported affine model, not discovered mathematics.

**Codex design gate verdict (2026-09-02):** Fixed 9-state quotient NO-GO. Affine-as-native NO-GO. Path dependence interesting but narrow (model-specific).

The R^n vs non-R^n mandate reframed: the coherent distinction is operational invariant vs coordinate artifact, model-discovered equivalence vs researcher-imposed labels. Recommended: one bounded predictive-state closure/refinement round using Nerode-style counterexample-guided right congruence.

**PSR-v1 result (2026-09-02, Codex evidence gate: NO-GO on headline claim):** Predictive-state refinement completed. 41 classes from 117 histories (14 suffixes in Γ). 3 refinement rounds. Right congruence NOT achieved (9 violations). Composition: 12/19 on selected-coverage subset (35 histories uncovered). On common 54-denominator: 12/54=22.2% vs parser 8/54=14.8%, 7.4pp gap not significant (Fisher p=0.229). **Reported 48.3pp surplus WITHDRAWN** — denominator mismatch invalidated it. Additional issues: (a) not valid Nerode refinement (classes merged 50→48→41 due to greedy averaging), (b) comparison unfair (quotient uses 14 suffixes + lookup table vs parser using only ground-truth abstract state), (c) simpler controls not run (kNN, memorization, last-action, shuffled transitions).

**Licensed sentence (Codex):** "In a transductive selected-coverage screen, a thresholded response-signature partition correctly predicted 12 of 19 covered two-action class labels; because right congruence failed, 35 histories were uncovered, the parser was scored on a different denominator, and simpler matched controls were not run, no predictive surplus or quotient action law is established."

**PSR-v2 result (2026-09-02, Codex evidence gate: INVALID_PSR_V2):** Attempted corrected adjudication. Frozen train/test split (d0+d1=63 construction, d2=54 evaluation), argmax quantization, construction-only transition table, full null ladder (parser, kNN, last-action, shuffled). 702 model calls. 21 classes from 6 suffixes. Coverage: 19/54=35.2%.

**Codex evidence gate verdict: INVALID, not a valid scientific negative.** Multiple outcome-bearing deviations invalidate confirmatory adjudication: (a) horizon safety violation (d1 suffixes query d2 behavior — cannot be assumed to "help the quotient"); (b) argmax instead of approved Q16 quantization — within-class TV 0.1542 (max 0.4998) confirms classes are not approximate predictive-equivalence classes; (c) right congruence "0 violations" is VACUOUS — all 9 d0 anchors are singletons, no eligible pairs exist to test; (d) action descent 0/0 is untestable, not a result; (e) coverage 35% vs required 90%; (f) no actual recurrent-state substitution (only signature comparison); (g) kNN comparison is target-informed (evaluation signatures used as kNN inputs). The run failed as an implementation of the approved design but does not falsify a stationary response quotient.

**Licensed sentence (Codex evidence gate, verbatim):** PSR-v2 is an invalid confirmatory adjudication, not a valid negative result: the implemented argmax quotient used out-of-horizon response laws, its zero-violation right-congruence diagnostic was vacuous because all depth-0 anchors were singleton classes, composition covered 19/54 histories, and action descent

and causal substitution were not tested; RCQ is therefore closed on this task by the bounded-round protocol, not empirically falsified.

**RCQ on entity-location tracking: CLOSED** — administrative/protocol closure following an invalid adjudication. Not recorded as empirical falsification. The PSR/RCQ line on this particular entity-location task is closed under the bounded one-round rule; do not run PSR-v3.

**Transferable residue (Codex):** (1) Horizon-custody law: depth(history)+ horizon(suffix) <= construction horizon. (2) Nonvacuity certificate: congruence/descent requires multiply represented source classes; 0/0=N/A. (3) Approximate identity: argmax cannot define predictive equivalence; need explicit within-cell diameter bound. (4) Fair evaluation: score abstentions on common denominator; task-clustered inference. (5) Causal boundary: response similarity is not substitution. (6) Multiple independently worded histories per intended operational state.

Runner: experiments/run_psr_v2.py. Results: experiments/results/psr_v2/.

<details>
<summary>Historical Falcon suffix-action construction — superseded</summary>

***Terminal correction:** The measurements in this block were produced through the defective multi-token cached continuation. Their arithmetic is retained as a runtime diagnostic; the central/native-object, faithful composition, contraction, and causal reactivation interpretations are not claim-bearing. The uncentered simultaneous-band reanalysis also carries no decision weight.*

### Historical suffix action algebra construction (2026-09-03)

Distance-from-claim: **2 after runtime audit** — formal diagnostic, not faithful-model evidence.

Formal construction of the behavioral suffix-action algebra from SVB data. Defines native mathematical objects using only legal actions, response-equivalence places, composition, reachability, and directed cost. No imported R^n geometry.

**Objects defined:** SVB transition world (D1 specialization), behavioral places Q = Z/~ (D5), suffix transition monoid S = A*/≡_Q, idempotence / residuation / commutator defects with binding thresholds, accessibility languages L_θ(q), directed cost c_θ(q).

**Hypotheses:**

- H-LRB: S is approximately a left-regular band (a^2 ≈ a, aba ≈ ab). **REFUTED** (2026-09-03). Idempotence holds but absorption fails: R(C,P) = TV(CPC,CP) = 0.091 [0.081, 0.100] and R(P,C) = TV(PCP,PC) = 0.141 [0.126, 0.154], both LBs > εTV = 0.06. Generators C and P are panel-locally approximately idempotent (passes registered rule). Bandness of composites (e.g., (CP)^2 ~ CP) is UNTESTED. Frozen predictions in theory/frozen_predictions_CP.txt are falsified.
- H-BAND2: (CP)^2 ~ CP and (PC)^2 ~ PC (free band). **REFUTED** (2026-09-03). BAND2(CP) = TV(CPCP,CP) = 0.107 [0.098, 0.117], LB > 0.06.

BAND2(PC) = TV(PCPC,PC) = 0.122 [0.108, 0.136], LB > 0.06.

The monoid is NOT a band. Composite idempotence fails.

- H-SAT3: CPCP ~ CPC, PCPC ~ PCP (length-3 saturation, non-band).

**BEST FIT, FORMALLY INCONCLUSIVE** (CP arm passes: TV=0.050, UB=0.056 ≤ 0.06;

PC arm borderline: TV=0.052, UB=0.064 > 0.06; heterogeneous across cells).

Registered joint rule requires both arms; licensed as best fit, not confirmed.

- H-GEN-IDEM: only generator idempotence. **REFUTED** — SAT3(CP) UB ≤ 0.06.
- H-Truth: suffix actions conjugate under truth-reversal involution. UNTESTED.

**Theorem:** truth-congruence reversal obstruction (proved on raw states Z).

**Empirical grounding (d3, 27 cells, TV metric):**

- Generator idempotence: I(C) = 0.050 [0.042, 0.058], I(P) = 0.021 [0.018, 0.023]. PASS (registered rule).
- Absorption: R(C,P) = 0.091, R(P,C) = 0.141. REFUTE — third suffix does real work.
- Noncommutativity: N(C,P) = TV(CP,PC) = 0.091 [0.075, 0.107]. Large, confirmed.
- CPC-CP sigma difference = +0.015, CI [-0.003, 0.031] — NOT established (crosses zero).
- PCP-PC sigma difference = +0.071, CI [0.044, 0.094] — established (history-dependent reactivation).

**Additional finding:** Generator idempotence does NOT propagate to products.

CPP vs CP: TV=0.063, CI [0.056, 0.070] — formally inconclusive (CI crosses ε_TV).

PCC vs PC: TV=0.076, CI [0.062, 0.089] — marginal evidence (LB barely above ε_TV).

These panel-level approximations are not a congruence.

**Pairwise structure (12x12 TV matrix, 2026-09-03):**

- Terminal cluster: {CC, CPC, CPCP, PCP, PCPC, CPP} all pairwise TV ≤ 0.096.

Tightest non-trivial pair: CC-CPCP (TV=0.035).

- Funnel property: after CP, both continuations converge — TV(CPC,CPP)=0.039.

CP is an approximate right zero (next generator doesn't matter).

- Surprising equivalence: CP ≈ PCC (TV=0.047).
- Contraction: C is contractive (mean r=0.67), P is near-isometric (mean r=1.03).

C drives convergence toward the terminal zone; P shuffles without shrinking.

- All conclusions scoped to cached-continuation pathway. Full-forward and

chunking-invariance checks open.

**Right-continuation test (2026-09-03):** CPC does NOT absorb C

(TV(CPC,CPCC)=0.060, INCONCLUSIVE). PCP does NOT absorb P

(TV(PCP,PCPP)=0.072, LB>ε). CPCPC genuinely different from CPC

(TV=0.099, REFUTE). The monoid does NOT collapse to a finite quotient —

words continue evolving past length 3. Sigma degrades with suffix length:

CPC=0.486 → CPCC=0.439 → CPCPC=0.393.

**Execution-mode diagnostic (EMI, 2026-09-03): all registered point contrasts exceeded tolerance.**

4 modes (L/W/G/F), 9 core words, 27 cells. 2079 calls, 5568s CPU.

All 54 word×mode-pair point comparisons exceeded the registered tolerance; the

post-hoc simultaneous max-statistic artifact was uncentered and is nondecision-

grade. L vs W: TV 0.33-0.42 (query-boundary

artifact). W vs G: TV 0.05-0.18 (generator packaging matters). Mode F

(full text, no cache): ALL defects NEAR (TV<0.016) — algebra vanishes

without KV caching. Spearman L/W/G: rho 0.54-0.69 (moderate structural

correlation). F vs all: rho -0.007 to 0.189 (uncorrelated).

</details>

**RUNTIME GAP LOCALIZED (2026-09-03): HuggingFace Mamba state continuation.**
Falcon-H1 `torch_forward` starts the Mamba SSM recurrence from ZERO state for multi-token cached continuation (`seq_len > 1`) instead of passing the cached recurrent state. `modeling_falcon_h1.py` line 819: `previous_states = torch.zeros_like(states[:, :1])`. Both `mamba_chunk_scan_combined` and `causal_conv1d_fn` accept `initial_states`; this path does not pass them. On the minimal registered probe, one-shot versus multi-token two-shot TV was 0.118, while one-shot versus tokenwise decode TV was 0.000000.

**Revised interpretation:** The recorded suffix algebra is not evidence for architecture mathematics. Its execution path omits direct cached recurrent and convolutional history, and the registered response law changes sharply relative to full-forward and tokenwise execution. Prefix information may still reach later computation through attention-conditioned hidden states, so the source inspection does not prove that Mamba receives no prefix influence or that the runtime gap causes every recorded suffix contrast. Full-forward is the faithful reference for the registered comparison; all Falcon-H1 SVB runs used the affected cached continuation and therefore require corrected remeasurement.

**Decode mode verification (2026-09-03, COMPLETE):**
Across four fixed 27-cell conditions, tokenwise cached processing of the 12-token query produced condition-mean 11-bin response laws within `1.2107523675e-6` TV of full-forward processing. The legacy multi-token cached query path was `0.546–0.885` TV from full forward. The rounded multi-token inflation range was 1.7x to 9.0x.

| Condition | Buggy σ | Correct σ | TV(decode,full) |
|---|---|---|---|
| d1_s0 | 0.747 | 0.142 | 9.3e-7 |
| d1_s1 | 0.722 | 0.080 | 5.3e-7 |
| d2_s0 | 0.691 | 0.402 | 1.2e-6 |
| d2_s1 | 0.677 | 0.292 | 1.1e-6 |
